CANETE, a seaport town in the N. part of Peru, is the capital of a province of its own name in the department of Lima. Pop. of the province in 1850, 17,658.

CANEY FORK rises in the Cumberland mountains in Tennessee, and joins Cumberland river at Carthage, Smith co.; length, 125 m.

CANFOO, or CANFU, called by the Chinese Kanpoo, an ancient town and seaport at the head of a bay in the province of Che-kiang, China. It was originally the port of Hangchow, and 2 Arabian travellers who visited the place in the 9th century describe it as the port for all the vessels entering China. The stream which once flowed past it, however, has become choked up with sand, and it is now deserted. Its trade has been transferred to Canton and Chapoo.

CANGA-ARGUELLES, José, a Spanish statesman, born in Asturias in 1770, died in 1848. He was deputy from Valencia to the cortes of 1812. After the return of Ferdinand his constitutional tendencies were so unwelcome to the court that he was banished to Peniscola, in Valencia, whence he was not recalled until 1816. After the revolution of 1820 he was appointed finance minister. While in this office he presented to the cortes a report on all the church and state property of Spain, and a paper on the condition of the Spanish revenue. In this remarkable paper he showed the insufficiency of the national income to meet current expenses, and that a very large deficit was annually accumulating. To meet this, he proposed an immediate loan, and to sell ⅓ of the ecclesiastical property, together with the small possessions in Africa, and to levy indirect taxes. These proposals created furious discussions, and, being hotly opposed, were adopted only in part. In 1821 Canga retired from the ministry, and in the following year was returned again as member of the cortes. From his seat he maintained his old attachment to the constitution, and insisted strongly on the necessity of reform in the finance department. When the constitution was suppressed, he fled to England, where he wrote a useful work, "Dictionary of the Spanish Exchequer, for the use of the Supreme Direction." He returned to Spain in 1829, but did not reënter upon public life. He afterward commenced a history of Spain.

CANGALLO, a town of Peru, on one of the head branches of the Apurimac, capital of the province of Cangallo, which has a population of 20,027.

CANGE, Du. See DU CANGE.

**CANGIAGO**, or **CAMBIASO**, **LUCA**, a Genoese painter, born at Genoa in 1527, died in Madrid in 1585. Invited by Philip II. to his court, to assist in the decoration of the Escorial, he painted in the ceiling of the church his picture of "Paradise," his most admired work.

**CANGOZIMA**, or **KANGOZIMA**, a fortified seaport of Japan, situated at the head of the bay of Cangozima, in the island of Kiou-Siou. The bay is 38 m. long, and from 6 to 12 m. wide.

**CANICATTI**, a town of Sicily, on the Naro, pop. in 1850, 18,000, with extensive mines of sulphur in the vicinity.

**CANICULA**, the dog star, also called **Sirius**, the brightest of all the fixed stars. The days when it rises and sets nearly at the same time with the sun are called dog days. It was much observed by the Egyptians, because the rise of the Nile occurs in the dog days.

**CANINA**, **LUIGI**, an Italian archaeologist and architect, died in Florence, Oct. 17, 1856, officiated for several years as professor of architecture in Turin, conducted the excavations at Tusculum in 1839, and those of the Via Appia in 1848, and wrote on them and also on church architecture, and on various kindred subjects.

**CANINI**, **GIOVANNI AGNOLO**, an Italian painter and engraver, born in Rome in 1621, died in 1666. He was a pupil of Domenichino, and his martyrdom of St. Stephen and of St. Bartholomew are 2 admirable altar-pieces.

**CANINO**, **PRINCE OF**. See **BONAPARTE**, **CHARLES LUCIEN JULES LAURENCE**, under **LUCIEN**.

**CANIS MAJOR**, a southern constellation containing the dog star.—**CANIS MINOR**, a northern constellation, whose appearance in the morning twilight gave the Egyptians notice of the approach of dog days.

**CANISIUS**, **PETRUS**, a German Jesuit, born at Nimeguen, May 8, 1524, died at Freyburg, in Switzerland, Dec. 21, 1597. His original name of De Hondt (the dog) he Latinized according to the usage of the time. He took a prominent part in the council of Trent in 1545, was selected by the emperor Ferdinand I. for his preacher, and did not cease until his death to hurl reproaches against Protestantism. He was the first who held the office of provincial, or ecclesiastical governor of the Jesuits in Germany, contributed powerfully in spreading the influence of the order in that country, and established Jesuit colleges at Prague in Bohemia, at Freyburg in Switzerland, and at Augsburg and Dillingen in Bavaria. He is the author of a larger and a smaller catechism. The best edition of the former is that of Antwerp of 1587, and the most recent edition that of Landshut, of 1842. The smaller catechism (*Institutiones Christianæ Pietatis, sive Parvus Catechismus Catholicorum*) has passed through more than 100 editions since its first publication in 1566, and has been translated into most modern languages, a new edition of the German translation having been published at Mentz in 1840.

**CANITZ UND DALLWITZ**, **BA** sian general and statesman, born in April 25, 1850, served in the Hessian army, and subsequently, after a had been concluded between the a and the Russian army, remained at the latter until 1813, when he returned. He was afterward present as the P gate in the Russian campaign again and officiated as ambassador at Co Hanover, and Vienna. In 1846, a death, he took his place as minister affairs, until March 17, 1848, when he his resignation in common with the others of the Bodelschwingh cabinet. 1849, Count Brandenburg sent him with a view of disposing the Aust ment favorably toward the Prussian, new German league; but he failed to any thing. He was the reputed author of the "Reflections on Strauss's Life of Jesus," appeared at Göttingen in 1837. He was author of a work on cavalry.

**CANKER**, a form of aphthous ulcer of the mucous membrane of the mouth, commonly seen in children, and connected with derangement of the digestive system. The ulcers are small, circular, filled with a white thick exudation, surrounded by a circle of inflammation, very sensitive; they originate in small, painful prominences, which are soon converted into vesicles, hence the name "vesicular matitis." When the ulcers are few they quickly disappear, their cicatrization hastened by astringent or caustic applications, and by the exhibition of gentle aperients. In unhealthy children the ulcers are apt to be profuse, and tend to spread to the oropharynx and stomach; in such cases there may be considerable constitutional disturbances, requiring the use of purgatives and alteratives. The predisposing cause is any thing that enfeebles the system, such as exciting cause any irritation in the mouth, foreign bodies, decaying teeth, or a general debility. The usual seat is on the inside of the lips and cheeks, and on the tongue, but may occur on almost any part of the mucous membrane. Billard represents the disease as a result of the secretions of the muciparous glands or in many cases they are too superficial. This is the explanation. When they occur in debilitated constitutions, in the course of febrile diseases, they form a painful and dangerous complication, from their liability to take on a gangrenous aspect. Appearances may occur epidemically in certain seasons, but are generally only a local affection, and for their removal only local application of these is the nitrate of silver, which changes the surface of the ulcer, and promotes rapid cicatrization; other favorite but less successful remedies are solutions of sulphate of copper, and gentian. The chlorate of potash, used internally, is specially

superficial affections of the buccal mucous membrane. The return of the ulcers may be aided by attention to the general rules of hygiene, especially to the diet, which should be nutritious, and easily digested.

**CANKER WORM**, the caterpillar of a noctuidopterous insect, or moth, of the subgenus *træ*, Linn. (or *phalanites*, Lat.), of the subfamily *Lyvernidae*, and the genus *anisopteryx*. The moths from which canker worms are derived and the females are wingless. The males have antennæ with a downy edging on each segment; the wings are large and silky, and, when the fore wings entirely cover the hind wings, the fore wings are ash-colored, with a dark spot on the front edge near the tip, and several white bands crossing them, with black dots along the sides and outer margin; the hind wings are pale ash, with a blackish dot in the middle; the expanse of wings is about 1.5 inches. This is the common American species, which is smaller and darker than the European and is the *A. vernata* (Peck); there are several other species, without the whitish bands, such as the *A. pometaria* (Harris). These worms usually come out of the ground about the middle of March, sometimes a little earlier according to the season, and continue to be seen for about 3 weeks; in mild winters they have been seen in every month from March to October; the females are most numerous in autumn and winter, and the males most numerous in the spring. The wingless females creep up the trunks of the nearest trees, and are killed in a few days by the males, when the mating takes place; the eggs are placed on the trunks in clusters of 60 to 100, the number varying by each female, and are attached with a proof varnish; soon after this the eggs hatch. The eggs are hatched from the 1st of May, at the time when the red worms, or *Lyvernidae*, and the young leaves of the trees begin to start; the young worms gather on the tender leaves, and creep into the buds and flowers; at first they make but small holes, but at last devour all the pulpy part of the flowers of the apple, elm, cherry, plum, lime, and other native and cultivated trees. The worms vary considerably in color within the limits of the species; when very young they are of a brown color, with a yellowish stripe down the back, the belly whitish, and 2 bands of black across the head; when fully grown they are ash-colored on the back, black on the sides, with a pale yellowish line below it; some are dull greenish yellow, others green with black stripes on the back, and others clay-colored; when full-grown they are nearly an inch long. After eating for about 4 weeks, they quit the trees on which they have been feeding; some creep down, but most let themselves fall from the branches by threads, as every one has seen by the roadsides; they burrow immediately into the earth, from 2 to 6 inches deep, according to the nature of the soil; they make little cavities in the earth by turning

themselves round, and are changed into chrysalids within 24 hours, those of the females being the largest; the chrysalis state may continue until the following spring, or it may cease in mild weather in the autumn. They come out of the ground mostly in the night. Nature seems to desire to confine the canker worms to a limited space, as the females have no wings, and bury themselves within the spread of the trees from which they descend; but accidents have extended them to remote localities. The canker worm has 10 legs, 6 anterior jointed ones, and 4 fleshy prop-legs behind; they are called span worms and loopers from their singular mode of progression; from the absence of the 8 intermediate pairs of prop-legs in the centre of the body, when creeping they arch up the back and bring forward the hind part of the body, and then, resting on their prop-legs, they stretch out to their full length in a straight line, and so repeat the spanning process.—The ravages of canker worms are not very apparent until June, when they are most voracious; but then the leafless and apparently withered fruit trees and elms afford a melancholy spectacle. The best way of destroying the canker worm is to prevent the females from ascending trees to deposit their eggs; various methods have been resorted to for this purpose, consisting in the application of viscid substances to the trunk, immediately on the bark or on strips of cloth, paper, or board; tar is generally used, and it should be applied from November, and renewed daily as long as the insects come forth; tin troughs filled with cheap oil a few feet above the ground have been tried with success on a small scale; melted India-rubber has been recommended in England. When the worms are on the leaves, they may be destroyed on small and choice trees by dusting air-slacked lime on them when wet with dew. Showering with a mixture of whale-oil soap in water, in the proportion of 1 pound to 7 gallons, will kill the worms without injuring the leaves or the fruit. By jarring the limbs many worms will descend with their silken threads, and may be easily killed. After they have entered the ground, they may be killed by digging or ploughing under the trees, scattering a few grains of corn, and turning a few hogs into the orchard; these animals will root up and devour the chrysalids, and will crush many with their feet. Canker worms are eaten by many species of birds; ground beetles also devour them; the potter wasp fills her clay cells with them as food for her young; ichneumon flies deposit their eggs in them, and the little maggots thence arising feed upon their substance; even their eggs are pierced by a small 4-winged fly, sometimes every one in a cluster being thus rendered abortive. No doubt beast, bird, and insect would be enough to keep the canker worms within their natural limits; but since the felling of the forests in which they naturally dwell, and the persecution of insectivorous birds which devour them, they seem to have increased in spite of

all man's destructive ingenuity. For fuller information on these pests, and the best means of destroying them, the reader is referred to Dr. Harris's treatise on the "Insects injurious to Vegetation."

CANNE, a village in the province of Bari, Naples. It occupies the site of the field of Cannæ, memorable for the defeat and fearful slaughter of the Romans by Hannibal, 216 B. C. The place is still called *Campo di Sangue*, or "field of blood."

CANNEL COAL. See COAL.

CANNELTON, a town on the Ohio river, Perry co., Ind.; pop. in 1853, 2,500. In the hills which surround it are found beds of cannel coal, lying in nearly horizontal strata 4 or 5 feet thick, and easily accessible. For the purpose of working these beds the American cannel coal company was incorporated in 1836, and to the improvements commenced by this company Cannelton owes its present flourishing appearance. Its mineral wealth, and its advantages as a manufacturing town, have produced such a rapid growth of population, that although 12 years ago it contained only 4 or 5 log cabins, it is now the largest town in the county, and contains several churches and elegant residences, a newspaper office, and a large cotton factory. This factory, which is called the Cannelton cotton mill, is built of variegated sandstone, and presents, from the river, an imposing appearance. It can manufacture 40,000 yards of sheetings per week. Fire-clay, limestone, and fine sandstone for building purposes, are found interstratified with the coal.

CANNES, a seaport town of France, pop. 5,557, in the department of Var. It is regularly built, lies on the road from Toulon to Nice, and has a fine promenade along the coast. The climate is unhealthy, but the neighboring country is fruitful in vines, olives, and oranges. An active trade is carried on in these products, and especially in sardines and anchovies. Opposite Cannes lies the St. Marguerite, one of the 2 isles in whose citadel the "man in the iron mask" was first imprisoned. Napoleon landed here March 1, 1815, on his return from Elba. A charming villa in the vicinity has been for several years the residence of Lord Brougham. An English chapel was erected at Cannes in 1855.

CANNIBALS, a term probably derived from the Indian language, and of the same family as the word Caribee, or Carib. Columbus relates that he was in great fear of the Carribals, which word was probably corrupted into cannibals. It signifies, as now used, eaters of human flesh. This practice is not, however, confined to the Caribs. The Greeks knew of tribes anciently who ate human flesh, and called them anthropophagi. In modern times, not only the aboriginal Caribees, but various tribes of the South sea islands, are given to the practice, which they generally indulge upon captive enemies.

CANNING, GEORGE, a British statesman,

born in London, April 11, 1770, died at the duke of Devonshire's villa at Chiswick, Aug. 8, 1827. His father, who was of an ancient family of Warwickshire, died when he was only one year old, and his education was left to his mother. She supported herself by performing upon the stage, until she was again married. He was sent, at the expense of an uncle, to Eton school, and from the first evinced the most decided literary abilities. He wrote poetry before he was 16, and engaged with some companions in the publication of a weekly periodical, called the "Microcosm," which was continued for a considerable time. From Eton he went to Christchurch, Oxford, where he gained high academical honors, and took a brilliant position as an orator. His vacations introduced him, by means of the friendship of Sheridan, to the conversation of Burke, Fox, Lord John Townshend, the duchess of Devonshire, and other leading personages of the whig party. It was through their influence, doubtless, that he relinquished his intention of studying for the bar, to devote himself to politics. He had not, however, entirely adopted their political principles, and in 1793 he allowed himself to be brought into parliament, on the tory side, by Mr. Pitt. During the whole of his first session, he had the sagacity to refrain from taking part in the debates, and to surrender his whole leisure to the careful study of the forms and practices of parliamentary assemblies. This enabled him, when he undertook to address the house, the next year, to do so with ease and self-possession, and to produce a marked effect. His success, indeed, so convinced Pitt of his ability, that the skilful minister suffered him to conduct the argument in several of the most important subsequent discussions. In 1796 he took office as under-secretary of state; in 1797 he commenced with others the publication of the political paper, the "Anti-Jacobin;" in 1798 he engaged in Wilberforce's plan for the abolition of the slave trade; in 1799 he was appointed one of the commissioners for managing the affairs of India; in 1800 he married Joanna, youngest daughter of Gen. John Scott, with a fortune of £100,000; and in 1801 he retired from office, to participate with Pitt and others in a most effective parliamentary war upon the administration. It was during the several subsequent sessions, while acting in opposition, that he acquired his highest reputation as a keen, sarcastic, witty, and eloquent speaker. Few men have appeared in parliament equal to him in showy declamation, cutting irony, and sparkling wit. On Pitt's return to office in 1804, he was made treasurer of the navy. After a brief retirement in 1806, occasioned by the death of Pitt, he reappeared in office in 1807, as secretary of state for foreign affairs, under the administration of the duke of Portland, in which position he particularly distinguished himself by the ability and skill, as well as by the spirited composition, of his state papers. In 1809 he became involved in a

growing out of the Walcheren expedition with one of his colleagues, Lord Castlereagh, which led to a duel, and afterward to the separation of both parties, together with the duke. During the session of 1812 Canning advocated the Catholic emancipation bill, set on foot by Mr. Grattan; and the success of that measure of justice and moderation was greatly indebted to the eloquence of Mr. Canning. He was the same day returned to parliament from Liverpool, and gave him its support again in 1814, and in 1820. In 1814 he was sent ambassador to Portugal; in 1816 he became president of the board of control; and in 1820, to participate in any way in the trial of Caroline, resigned his place, and travelled on the continent. In 1822, the response of governor-general of India was offered to him, and he had made his preparations to leave England, when the sudden death of Castlereagh, by suicide, recalled him to his post of secretary of state for foreign affairs. While in this position, in 1825, he refused to recognize the independence of, and to limit diplomatic intercourse with the several American republics, and soon carried his policy into effect. In 1827 he was appointed secretary to the dissatisfaction of the tory party, which, under lead of the duke of Wellington, Lord Bexley, Viscount Melville, Mr. Peel, and others, deserted him, and commenced to solicit an alliance with the whigs. Supported by Lord Brougham, Sir Robert Burdett, and Mr. Tierney, but had to meet a most formidable opposition, which required all the dexterity of his logic, the sharpness of his wit. Declaring himself finally inimical to parliamentary reform, to the repeal of the test and corporation laws, he was left without a party, and it was the vigor of his foreign policy alone which kept him in the ascendant. He spoke for the first time on June 27, 1827, and the next month signed the treaty between England, France, and Russia, for the settlement of the affairs of Greece (one of the earliest which he wrote in his youth was on the subject of Greece), when he retired for a short time to the duke of Devonshire's villa at Chiswick, where he died. A newspaper of the day, the "Examiner," which had not been friendly to him in politics, because of his want of liberality in the conduct of his foreign affairs, yet closed the announcement of his death with the following just and beautiful eulogium of his character: "On Canning, it is unnecessary for us now to dwell; the estimation of it has been often made. He was the last of the rhetoricians. He was less an orator, he would probably have been a greater man. He followed, however, the tawdry fashion of his day; and the glitter and finery could not disguise the thence they encumbered. Self-complacency was a prominent feature of his character, and

the nice description, *Omnium quæ diacrat feceratque arte quadam ostentator*, was peculiarly applicable to him. But if ever vanity was excusable in man, it was excusable in George Canning, who, endowed with every choicest gift of nature, had risen from a low condition to the highest office in the state, and seen centred in himself the best hopes of the best men in the civilized world. We read in the tales of superstition of men who have made compacts with the fiend; a Faustus could hardly have desired to be more than a Canning. A fine person for the love of women; a mind for the admiration of man; a golden tide of fortune which had its slacks, indeed, but no ebb; and a death which has abruptly left his character, as it was gilded with the glow of a world's best hopes." His "Speeches," with a memoir by R. Therry, 6 vols. 8vo, were published in London, 1828. He was buried in Westminster Abbey, near Pitt.—CHARLES JOHN, viscount, a British statesman, son of George Canning, born at Gloucester Lodge, Brompton, Dec. 14, 1812; distinguished himself in the classics at the university of Oxford; represented Warwickshire in the house of commons in 1836; and on March 27, 1837, after his mother's death (on whom the peerage was conferred in 1828), became viscount, and took his seat in the house of lords. In 1841 he was made under-secretary of state for foreign affairs, and subsequently chief commissioner of woods and forests. In 1851 he took a prominent part in the great industrial exhibition. In the ensuing year he became postmaster-general, with a seat in the cabinet under the Aberdeen administration. In 1855, on the resignation of Lord Dalhousie, he was appointed by Lord Palmerston governor-general of India, which office he still retains (Aug. 1858). The formidable sepoy rebellion broke out during his administration, and he was as much censured for his leniency at the beginning of the outbreak, as for his severity afterward. His proclamation, confiscating the property of the natives of Oude, elicited a strong condemnatory counter-despatch from Lord Ellenborough, president of the board of control, and in the discussions in both branches of the British legislature was generally pronounced to be harsh and ill-advised.

CANNING, SIR GEORGE STRATFORD. See STRATFORD DE REDCLIFFE.

CANNON, implements of war for throwing heavy projectiles, as shot and shells, by the explosive force of gunpowder. The most ancient form of the cannon is the mortar, a short and wide-mouthed piece of ordnance, originally used for throwing stones, and now applied to casting bomb shells. Cannon for propelling balls are hollow cylinders of gun metal or bronze, an alloy of copper with 8 to 10 per cent. of tin, or they are made of cast iron; and some heavy experimental pieces have been made of wrought iron, but the number of this class in actual service is exceedingly small. The severe trial to which the metal is put when in use requires a

material of great tenacity and hardness—the former to withstand the force of the explosive fluid applied to burst open the gun, and the latter to resist the wearing action of the ball as it pounds down upon the surface it rests upon, when first struck and perhaps temporarily flattened by the force of the explosion; an indentation is thus produced, which continually grows larger, and is soon followed by another in the upper surface a little in advance of the former, which also increases till the gun is worn out by this lodgment, as it is called. Cast iron, in the improved methods of preparing it, combines the required hardness and tenacity with cheapness more perfectly than any other material. But as formerly manufactured it was very uncertain in its character, often being far from homogeneous in texture, and at the best estimated capable of resisting a force applied to tear it asunder of only 20,000 lbs. to the square inch, while the tenacity of bronze was rated at 80,000 lbs.; and this beside was regarded as more to be relied upon for uniformity of character than cast iron.\* Its inferior degree of hardness, however, to cast iron, and its great cost, limited its use to the smaller-sized pieces, for which it still continues to be employed; while for every thing above field pieces cast iron is the material in general use, and is likely to take the place of bronze altogether. In strength, it may safely be rated as equal or even superior to that of bronze, as will be seen by reference to the experiments referred to below. Wrought iron possesses the greatest tenacity, but is deficient in hardness. The greatest objection to its use, however, is the difficulty of constructing large masses of wrought iron by continual reheating and forging, as new pieces are added and combined with those previously put together, without causing portions to change their texture and undergo a partial crystallization, thus weakening the mass without any sign of this change being visible. All the earlier guns previous to the 15th century were made of wrought iron, commonly of hoops incasing bars of the same material. It was by the bursting of such a piece in 1460 that James II. of Scotland was killed. In recent times wrought iron has been used with other materials in experimental guns made by a variety of methods, as over a lining of steel and over cast iron; and it has been put together and

welded in the form of hoops. A tenacity renders it the best material there is no question but these experiments be continued, till some method has been discovered of constructing a gun of perfect texture of it, hardened within to resist the wearing action of the ball. The facility with which malleable iron is now melted and cast to produce cast steel suggests this as a means of accomplishing this result. The improvements which have been made in all branches of industry, it is a marvel that cannon in general are not materially improved than those made 50 years ago. A 10-inch diameter of bore is now the standard instead of 7 inches, their strength proportionably increased, for the range is not so great as that of the old. In our own forts a 24-pounder was the maximum size in 1820. In 1850 there were 10-inch bore, carrying balls of 100 lbs. Attempts have since been made to construct larger pieces, but the difficulty of their enduring and safe in use has increased rapidly with the increase of their size. Little is gained in these attempts. The subject is constantly receiving the attention of scientific and practical men, and extended experiments upon a large scale have been conducted in many years past under authority of different governments. Our own has entered into extensive searches with great liberality, and the important reports of the officers and gentlemen engaged in the work have been published. The principal of these is the volume of Experiments on the Strength and Properties of Metals for Cannon, with a Description of the Machines for testing them, by Professor Treadwell, of Cambridge, Massachusetts, presented to the American Academy of Arts and Sciences in 1841, in a communication upon the same subject. He argues the practicability of constructing very large and efficient cannon, and proposes a method by which this may be done, which will be found in this article. In the year 1841, by the regulations of the Ordnance Department, an officer is required to make constant attendance at the foundries, where cannon are making, to examine and test them before it is used, as also in the first trial before another is cast from it. This has rendered it unnecessary to use a proof charge in the final proof, which would do serious injury to the gun without giving any indication of it; it has also been successful in increasing the average strength of cannon from 23,638 to 37,774 lbs. per inch. The strongest piece of iron ever tested was a sample of Greenwood (Orange co., Va.) brought by the proper number of experiments to that degree of density which was equalled with the greatest strength. In this the density was 7.304, and the tenacity 100,000 lbs. per inch. This method of

\* From the experiments of Major Wade upon the bronze cannon cast at Chicopee, Massachusetts, in 1850, it would appear that uniformity of character could hardly be attributed to bronze castings. Samples taken from different parts of the same gun showed a difference of density amounting to 20 lbs. in the cubic foot, and the extreme variation in samples from different guns amounted to 84 lbs. in the cubic foot; the difference in tenacity from a capacity to bear a strain of 23,108 to one of 54,531, being as 100 to 236. "The materials used in all these castings are of the same quality, they were melted, cast, and cooled in the same manner, and were designed to be similarly treated in all respects. The causes why such irregular and unequal results were produced, when the materials used and the treatment of them were apparently equal, are yet to be ascertained." The tendency of bronze to separate into alloys of different composition and strength, when cooled in large masses, was fully established in these experiments.

ling is a principle developed by experiments, made under the inspection

Wade, U. S. A. The transverse of some iron was found to be nearly 74 meltings and castings. From examined at the South Boston foundry in the same inspection, other curious developed, as that the cohesive power augmented by exposing the metal when

an intense heat; "and that this ceases as the times of exposure up to well ascertained) limit; and that, if beyond that limit, the strength of the hereby diminished." Experiments the same place upon the relative of cast iron bars 2 feet long and 2 are, made from metal kept in fusion periods of time before casting, made it hat the cohesive power of the iron, can be shown by its capacity to re-

strains, is increased by its contin- in fusion from 100 to 160, or 60

The longest time that the iron was ion was 4½ hours. The results of the ts of casting cannon in pairs, one one hollow, both of the same mixture appear likely to cause the old method

he cannon hollow at once, which oned in Europe in 1729, to be reëstab- d the universal practice of casting olid and then boring them out, to be

By means of a stream of water in- into the hollow core, as devised by lman, the cooling of the interior of is accelerated, while that of the ex- t is checked by surrounding it with . The metal is thus protected from

ontraction and consequent strain re- m differences of temperature. Two inch bore, of the same iron, possessing nd strength in a high degree, were solid and bored, and the other hollow. gun burst at the 73d discharge; the e withstood 1,500 fires, proving in- le by service charges. Another pair

guns burst—the solid cast gun at the and the hollow gun at the 249th. ous facts also are observed respecting of leaving the guns a long time be-

Eight-inch guns, cast solid and 30 days, stood but 72 charges; one of bore, proved 84 days after being cast, harges; another proved in 100 days charges; and another that lay 6 years ; cast stood 2,582 charges. The par-

st iron strained in the cooling by un- raction, are supposed by Major Wade ; themselves in the course of time, and e position giving the greatest tenacity.

st cannon ever made was constructed y Messrs. Horsfall of Liverpool, and to the British government. It is a ron gun, made by welding together bs of metal 3 feet long by 1½ broad, pon another in different directions, as was built up. The whole mass, ready

for boring, measured 15 feet in length, 8 feet 10 inches in diameter at the larger end, and 2 feet 10 inches at the smaller end, and weighed 26 tons. Its construction required the work of 7 successive weeks, day and night, and at times 40 men were employed at once about it. The hammer weighed 9 tons, and in using it especial care was taken, that the iron should never be struck when cold or partially so. It was first bored out 11 inches diameter, then 12½, and finally 13 inches, for a length of 13½ feet. No imperfection of any sort was discovered during the boring—no indication whatever of crystallization having commenced. When completed the weight was 21 tons 18 cwt., nearly 8 times that of the Stockton gun, which weighed 7 tons 17½ cwt. Its outside diameter at the breech is 44 inches; at the muzzle 27 inches. Its capacity is for a ball of 302 lbs. weight, which, with a charge of 90 lbs. of powder, is expected to be projected at least 5 miles. An attempt was made the previous year by Mr. Nasmyth to make a much larger wrought iron gun than this—one that should throw a ball weighing ¼ a ton 4 miles, with 225 lbs. of powder. By the unequal heating to which different parts of the great mass were subjected in the forging, the metal assumed in some places a crystalline form, by which it was so weakened, as to be considered unfit for use. It was proposed by Dr. Noad to endeavor to restore the fibrous structure by annealing. Prof. Treadwell regards these attempts, which are still continued in Europe, "to make wrought iron cannon by the process of fagoting or piling, as a strange engineering delusion." The tenacity required for cannon cannot be uniformly retained in iron subjected to repeated heatings and hammerings. He proposes to obtain the strength of wrought iron by constructing a cannon of cast iron, the thickness of the metal being ¼ instead of the whole diameter of the bore, as usual. "Upon this body he places hoops of wrought iron in 1, 2, or more layers. Every hoop is formed with a screw or thread upon its inside, to fit a corresponding screw or thread formed upon the body of the gun first, and afterward upon each layer that is embraced by another layer. These hoops are made a little, say 1/100 part of their diameters, less upon their insides than the parts they enclose. They are then expanded by heat, and, being turned on to their places, suffered to cool, when they shrink and compress, first the body of the gun, and afterward each successive layer all that it encloses." By making the hoops considerably smaller than the parts they surround, they accommodate themselves to the strain, and may, like all malleable bodies, be extended much beyond their power of elasticity without fracture. The screwing on of the hoops is regarded as essential, and also their being "spliced" to prevent their starting. The trunnions are to be welded upon one of the hoops. Cross fracture is guarded against by the cast iron body, and also by the outer rings breaking joints over the inner. Prof. Treadwell presents

a series of calculations, showing that a gun of 14 inches caliber, made in the manner proposed, and carrying a spherical ball of 874 lbs., will bear 68,960 lbs. to the square inch exposed to the fluid, or the pressure of 4,264 atmospheres. He also calculates that a pressure of 32,000 lbs. to the inch is required to give to a 14-inch shot an initial velocity of 1,600 feet a second, which is only half what the gun will bear; while, with a gun of this size, made of cast iron alone, its power of resistance is limited, according to the old estimates of the strength of cast iron, to 20,000 lbs. to the inch, or less than  $\frac{1}{2}$  that which may be required to obtain the velocity. He further calculates that a cannon of any size may be thus constructed capable of sustaining the pressure of 4,264 atmospheres, and one so made of 80 inches diameter—if such were practicable—would have precisely the theoretical capacity of giving to its spherical ball, weighing 8,670 lbs., the velocity of 1,600 feet a second. A patent has been recently granted to Capt. Blakely, of the royal artillery, England, for constructing cannon upon this principle, using cast steel instead of cast iron for the body. M. Thiery has also proposed a somewhat similar method, viz.: lining the interior of the mould with bars of wrought iron the length of the gun, set on end, and arranged at intervals of 8 inches or thereabout. When the cast iron is run into the mould the bars adhere to it, and the texture of these is not materially affected, excepting being partially changed to steel on the surface next the cast iron. The gun is then to be encased in hoops of wrought iron shrunk upon it, and the trunnions welded to one of them.—The Lancaster gun differs from other cannon in the bore being shaped very much as in some rifles, in a twisted ellipse or an elliptical twist. The form of the ellipse, however, in the rifle is but faintly expressed in the 2 opposite twisting grooves; in the cannon the greater proportional size of the grooves gives the elliptical form. These guns were found in practice in the Crimea to have an immense range, but they were uncertain in their aim, and enormously expensive, each discharge costing £20. Some of them burst in the most destructive manner; but whether this was owing to their being too light for their charge and weight of ball, or to the tendency of the ball to go straight forward, and thus wedge itself in attempting to pass the very gradual curve of the rifled bore, is undetermined. The principle of its construction seems to be a good one. The gun invented by Colonel Cavalli, of the Sardinian army, is somewhat upon the same principle. It is double-grooved, giving about a three-quarter turn to the projectile. This is of an oblong form, of cast iron, pointed at the top, convex toward the powder, and having 2 ribs running lengthwise to correspond with the grooves in the gun.—The greatest improvement recently introduced in the form of cannon, is in reducing the proportion of metal between the muzzle and the trunnions, which is found in guns of the

common mould to be largely in weight is thus placed about the strength is needed. The United States for the new are regarded as the most perfect constructed. Their peculiar proposed by Capt. Dahlgren, of the U. whose name they are generally length, range, and weight, the 8-in of Dahlgren does not materially differ from the 32-pounder, regarded as the best on board ship. Those of greater length are proportionally larger, with range also proportionally increased, as appears by the following from the Ordnance Manual:

*Dahlgren's 8-inch shell-gun*

Length of bore.....  
Weight.....  
Range at 5° elevation, at 9 feet above water level, charge 9 lbs.....

*Navy 32-pounder (Avery).*

Length of bore.....  
Weight.....  
Range at 5° elevation, 9 feet above water line, charge 9 lbs.....

A 10-inch Dahlgren has a length of 1 The casting of heavy cannon is rare at the blast furnaces where the metal is obtained from the ores. The quality of metal obtained is too uncertain, and is also inferior in strength to the same iron after several times remelted. The pig iron from the smelting establishments are of various grades of foundry iron, from the toughest gray metal to the hardest white metal, and these are mixed at the foundry and remelted according to the judgment of the founder. As in the casting of iron in blast furnaces—reverberatory or cupola furnaces—usually employed to furnish the metal for single casting, each supplying, it may be several tons. The metal, as it runs from the ladle, they are tapped, flows through channels in the sand into a reservoir, from which channels in the sand lead over the moulds, which have been prepared in the moulding bed or floor of the foundry. The liquid iron flows down these runners, and are slowly and steadily filled, without being conveyed with the metal to disturb the settling, or to injure its texture. The result is, perhaps, better attained in the casting of guns, the liquid metal being introduced into the mould at their lower portion. Several guns are usually moulded in the same sand mould is in sand enclosed in a cast-iron, called a gun box, made of several pieces which are bolted together as the crane one upon another in the shape of a clumsy imitation of the form within. The sand which fills the box receives its impression from the pattern, between which and each gun is a thin section of the case, in which the metal is poured in small quantities at a time, and is then rammed with clay to the proper shape, and the flat surface of each block of sand is which is to coincide with the

ckened over with a wash of fine charcoal and red water, to prevent adhesion as the differences are moved. By keeping the transverse sections slightly separated as the mould is dried, the sand projects a little, so that no sand can find its way between the sections making a fine joint. The gun box stands in the pit on its end or breech, the gun head, or portion beyond the mouth of the piece, and is cut off in the finishing, being below the level of the reservoir of the liquid metal. The lower section, in which is the mould of the breech and the cascabel, or extremity of the gun, is entire; the upper sections, commonly five in number, are in halves divided longitudinally, each half containing the mould of one-half the length of its section. These halves are bolted together by outside flanges, in such a manner that the sections are secured together. The trunnions, which make the axle on which the cannon is supported when in use, are moulded in the second section of the gun above the breech, lateral projections in the box affording room for the cylindrical cavities in which they are to be filled by the trunnions. The position of the mould is brought into a perfectly horizontal position by adjusting the box as the level indicates. Sometimes the whole is covered by ramming sand around the box, at the same time an open space is left around, which is covered over above to retain the hot air, preventing rapid cooling. The temperature of this space is sometimes increased by keeping burning in it for several days. Such is the usual method of casting solid cannon. By the improvement introduced by Lieut. Rodman, guns are now cast hollow of greatly increased strength. A tube formed on a tube of cast iron, which tube is water-tight and close at the bottom, is placed in the axis of the mould. Into the bottom of this through a smaller one placed in its axis, a current of water is discharged, and as the gun is being cast above the top of the piece constantly cooling the interior.—When the cannon is taken out of the mould, it is placed in a frame being secured at one end by the square block cast at the end of the cascabel, and the other placed in a collar a little back of the muzzle, in which it can revolve. The first operation is to cut off the head, which is 2 to 3 feet long. The object of this addition to the gun is, that if any portion of the casting, usually the head, may be rejected. The piece, if solid, is bored, a steel cutter fixed at the end of the frame made to penetrate, as the gun slowly revolves in its frame. When the boring is finished, the gun is finished upon the outside by the tools used in turning iron. It is then placed in the frame, the square block is cut off from the cascabel with a cold chisel, and the trunnions are dressed with the same instrument. A touchhole is drilled with a stock and bit. The piece is then ready to be proved, which is done in this country by testing the strength of a cylinder of the iron an inch in diameter and

2 inches long, cut out of the cannon, formerly from one of the trunnions, but now from the barrel near the muzzle. The specific gravity and other properties of the sample are carefully noted, and these, together with the trials to which it is subjected, and the hardness of the metal determined by a very exact method, give correct indications of the strength of the gun, without the necessity of submitting it to extreme proof by firing with constantly increasing charges, until the piece is destroyed. Indeed, to such perfection have these proofs been brought, that guns have been selected as of inferior quality from among a large lot, which, on reference to the books of the foundry, were found to have been the only ones of the lot made of hot-blast iron. According to the indications furnished by the tests, several guns are usually taken from each large lot of them, to be submitted to extreme proof—the selection being generally of those that appear to be the poorest, best, and intermediate qualities. These are fired commonly with charges of powder equal to  $\frac{1}{2}$  the weight of the ball, with one shot and one junk wad over it. The firing is continued, unless the piece previously bursts, to 500 rounds. Then 1 ball more is added with every discharge till the bore is filled. The powder is afterward doubled in quantity, and the bore filled with shot at each discharge. When it bursts, pieces are selected for further examination from the breech, near the trunnions and the chase. Guns are also tested by hydrostatic pressure, water being forced into the bore with increasing pressure, till it sometimes bursts the piece, or brings to light its hidden defects by opening the small fissures, that were concealed in the metal. It is not uncommon for it to appear upon the exterior of pieces, of which the thickness of the metal is 4 inches, exuding through as a thin froth, which collects upon the outside and forms drops and little streams. By this method, the exact pressure applied is known, and may be gradually increased to any desired degree. Sample bars are also cast together with the cannon, which furnish some indication of the strength of the metal. The different rates of cooling of the large and small mass, however, render their qualities somewhat dissimilar.—Bronze cannon are cast in a mould of loam, the pattern for which is prepared as follows: around a tapering rod much longer than the gun, soft rope is wound enclosing it entirely in its coils. Over this, when brought very nearly to the outer form of the intended body of the gun (not including the breech and the head), is plastered a layer of prepared clay or of plaster of Paris, and by causing the rod to revolve against a profile board having the exact outline of the gun, the model receives its shape. The models of the trunnions are then made of plaster and attached to it, and the whole is thoroughly dried. It is then washed over with a preparation of ashes or other substance to prevent adhesion, and several coatings of putty loam are laid on and dried till they resist the point of a knife.

These form the first layer of the mould. Other layers of moulding loam are added, till the whole thickness is about 2½ inches. The mould is then encased in iron bands, and more loam is laid on over them, to the thickness in all of 4 or 5 inches. Over this are put on more hoops and more loam again. The tapering rod is now drawn out together with the rope and the first coating upon it, and the plaster models of the trunnions are removed. The breech mould is prepared in a similar way, and set in an iron casing called the goblet mould, which supports the whole mass. The mould for the head is also made in the same manner. After being thoroughly dried, the 3 pieces are set up in the pit, firmly secured together, and the joints well plastered. Several moulds are usually prepared at the same time, and arranged in the same pit. The spaces around them are filled in with earth which is carefully rammed; the runners for the metal to flow in being made in this case to lead over the top of the head, as in casting iron guns. Such is a general description of the French method of casting bronze cannon, which is somewhat varied in this and other countries. When cast, the processes of boring and finishing are similar to those applied to cast iron guns, when they are made solid.—(See ARTILLERY, CASTING, and GUNNERY.)

CANNON, a central county of Tennessee, area 220 sq. m., drained by Stone's river and the Caney fork of Cumberland river. The surface is uneven and the soil generally fertile. Productions in 1850, 554,497 bushels of corn, 66,325 of oats, and 70,077 lbs. of butter; number of pupils in the public schools, 990. Capital, Woodbury; pop. 8,982, of whom 843 were slaves.

CANNONADE, in a general sense, the act of firing artillery during a battle or a siege. As a technical expression in tactics, a cannonade means an engagement between 2 armies in which the artillery alone is active, and the other arms are either passive or do not, at least, overstep the bounds of mere demonstration. The most celebrated instance of this kind is the cannonade of Valmy, in 1792. Kellermann awaited the attack of the Prussian army on a range of heights, his artillery placed in front of his troops. The Prussians drew up on the opposite range of the hills, brought forward their artillery, and the cannonade began. Several times the Prussian infantry formed for the attack and advanced a little; but, the French remaining firm, the Prussians withdrew again before coming within musket range. Thus the day passed, and the next day the Prussian army began their general retreat. In most general engagements such cannonades occur. They often form the 1st act of the performance; they serve to fill up the intervals between a repulsed attack and another attempt to dislodge the enemy; and they form the *finale* of most drawn battles. In most cases they serve more for purposes of demonstration than for any thing else, causing by a great waste of ammunition at long ranges that

almost incredibly small proportion of hits to misses which characterizes the artillery practice of modern battles.

CANNSTADT, a German town in the kingdom of Württemberg, on the Neckar, the seat of a superior bailiwick, a favorite resort of the people of Stuttgart, the distance from the capital being only 8 m.; also much frequented as a watering place, the 40 mineral springs in the town and its vicinity possessing a high reputation for their salutary effect upon bowel and nervous diseases. King William caused a beautiful Cursaal to be erected near the principal spring, the Wilhelmsbrunnen. Two establishments for cripples and scrofulous persons are favorably known abroad, and the mineral springs in the neighboring village of Berg are also resorted to. The Neckar is navigable near Caunstadt, and affords facilities for an active transit trade. Manufactures of cottons, woollens, and tobacco flourish, and the culture of the vine, as well as other agricultural products, diffuses prosperity among the population. In July, 1796, a battle was fought near the town, between the French and the Austrians. Upon the ruins of an old feudal castle of the house of Württemberg, which bore the same name, a Grecian temple, with the mausoleum of his queen, Catharine, was erected by King William in 1819. Many Roman antiquities have been found in the vicinity.

CANO, ALOXZO, surnamed EL RACIOYER, a Spanish painter, sculptor, and architect, born in Granada, March 19, 1601, died there, Oct. 5, 1685. He became so distinguished in each of these arts that his countrymen called him the Michel Angelo of Spain, although the title is due more to his versatility than to any resemblance in point of genius to the great Florentine. His "Conception of the Virgin," in the church of San Diego, at Granada, is considered his masterpiece. His works in sculpture and architecture are also numerous. He was a contemporary of Velasquez, and in 1639 was appointed court painter to Philip IV. His ungovernable temper on various occasions brought him in danger of the inquisition, and he was once put on the rack on suspicion of having killed his wife in a fit of jealousy, but was subsequently absolved from the charge. On this occasion his right arm was exempted from torture, as being *excellens in arte*. As an illustration of his whimsical character, it is related that on his deathbed he refused to take the crucifix from the priest on account of its bad workmanship.

CANOE (Fr. *canot*), a boat such as is built by savages, either by hollowing out a log or by stretching the skins of animals or the bark of trees over a light frame. Log canoes are made of large size from the white pines of the north and the cottonwood tree of the south, and are used principally for transporting freight upon rivers and smooth waters. Small ones serve the northern *voyageur* for short excursions; but for long expeditions, and even

overland from one river to another, is and rapids, the light birch canoe of us, which is easily carried upon the portage. These canoes are made of the white birch (*betula papyracea*) over light frames of white cedar. A selected of good size and sound bark, with great care the covering is stripped off entirely around the tree, and somewhat larger than the intended canoe. This is then fitted to the frame already set up in the river, and neatly fitted over it, the proper curvature of the bottom and sides being secured by flat strips of cedar, which are placed as ribs, and are attached at each end by longitudinal pieces which make the gunwale. Particular care is taken that the whole shall be unbroken, without a seam or joint. The sides pieces of bark are let in or cut out, as the shape of the canoe requires, the edges being sewed together with strips cut from the roots of the cedar, and covered over with tar and rosin, or with a varnish prepared from the gum of the balsam fir. One means the canoe is kept in repair while in use. Birch canoes made of bark are in the winter, last better than those of "summer bark." They are readily distinguished by their darker color, and are highly valued. Canoes of this kind are of all sizes, from those which may be paddled by one person of the water and carried by children, to those of 30 feet or more in length, in which Indians may undertake with safety long expeditions. A canoe of 16 or 18 feet may be carried for miles by an Indian without great exertion; and placed again in the water will convey him and his squaw and with all their worldly possessions. It is so unsteady in the water that one slips more easily than a white man, unaccustomed to it, and is suddenly than his feet placed unexpectantly upon smooth ice; the Indian rides fearlessly down the foaming rapids, and ventures into the salt water, where he may be seen leaping like a feather upon the water, managing to lift their bulky, slipshod passengers into his frail bark, with which he can safely to the shore.

(Gr. *κανων*, a rule). Collections of the writings of authors were called *κανωνες*, models. As applied to the sacred writings, the term has been used with various shades of meaning. Sometimes it signified merely a catalogue of persons or things belonging to the canon of books which were used in the church. In a more restricted sense it designated a list of all the books appointed to be read in public assemblies of Christians. In later times its significance was narrowed, and it was applied only to the collection of divine and inspired writings which are the rule of faith and practice. The New Testament was formed gradually in the course of years. The thought of gather-

ing together all the sacred books seems to have been suggested not before the time of Ezra, at which period the prophetic writings were closed and the historical works completed. It is supposed that the first 2 divisions, the "Law" and the "Prophets," were finished at or soon after the time of Nehemiah, while the 3d division, the "Holy Writings," including the book of Daniel, is believed by many recent critics to have been open some time longer. (See BIBL.) There is no knowledge respecting the author of the canon, and none respecting the precise date of its composition. The first mention of the collection is made by the son of Sirach, 180 B. C. Josephus speaks of it in its present form, enumerating all the books, and declaring that "during all this time which has passed, no one has dared to add to, to take from, or to change them." We may consider it to be a full collection of the books which the Jews, for reasons of their own, esteemed sacred or inspired. In their regard Moses held a place above all the prophets, being endowed with a peculiar inspiration; of course the writings ascribed to him were placed at the head of the compilation. The prophetic books and the compositions of David may have owed their place to the personal character and reputation of their authors. Others derived their title to inspiration from the nature of their contents, or from their great antiquity. Others again earned a place through the names attached to them, and were venerated as the compositions of Solomon, Ezra, Daniel, or Nehemiah. To whatever date we assign the completion of the canon, whether with the later Jews we suppose it finished after the time of Malachi (about 400 B. C.), or with modern scholars, later than Daniel, it is certain that this date was regarded as the close of the period of inspiration. For this reason, and likewise, probably, for the reason that they were not composed in Hebrew, the productions of later Jewish literature were not kept with the older books in the temple, nor included in the collections of sacred writings used for public reading. These works were held in higher esteem by the Greek Jews than by the Jews of Palestine, and the Alexandrine version, which the former regarded as inspired, had a large supplement containing Esdras, Tobit, Judith, Esther, Wisdom of Solomon, Ecclesiasticus, Baruch, Song of the Three Children, Susannah, Bel and the Dragon, 1, 2, and 3 of Maccabees. These compositions were not, however, even by the Greek Jews, considered as a constituent portion of the canon, but rather as an appendix to it, holier than any vulgar literature, and valuable as containing moral and religious instruction, but still not so peculiarly sacred as to be allowed to stand in the same rank with prophetic writings. The early Christians, being unacquainted with the Hebrew language, availed themselves of the Greek version, and naturally made use of all the books it contained, sometimes quoting the apocryphal books as if they were canonical; but when the subject became one of serious

study, the scholars generally accepted the judgment of the Jews. Still they were quoted with deference, used publicly, and in one or two instances spoken of as authoritative and divine.—The canons of the Greek church closely correspond with each other. The most ancient, that of Melito (A. D. 177), contained all the Jewish books excepting Esther, but excluded the apocrypha. With this catalogue agreed those of Gregory Nazianzen (A. D. 370), and of Amphilochius (A. D. 370). Origen's list includes all the Hebrew books, and the apocryphal Baruch. With him agree Cyril of Jerusalem (348), the council of Laodicea (363), and Epiphanius (368). Athanasius omits Esther, and retains Baruch. The apostolical canon, of uncertain date, admits 8 books of Maccabees, 1 of Judith, and recommends instruction in Ecclesiasticus. The catalogues of the Latin church coincide with the Jewish canon, in so far as they exclude no books reckoned as canonical by the latter; but 2 of them admit writings which the Hebrews rejected. Thus the canon of Augustine (A. D. 375) embraces the books Tobit, Judith, Wisdom of Solomon, Ecclesiasticus, 1 and 2 Maccabees; and the 3d council of Carthage adopted the same enumeration. Jerome, however, rejected these productions, chiefly, it would seem, because the number of canonical writings must be limited by the number of letters in the Hebrew alphabet. "The church," he said, "reads them for the edification of the people, but not to establish the authority of the doctrines of the church." The Catholic church, following the old Latin version, accepted the books regarded by the early Jews as apocryphal, declaring them to be canonical by a decree of the council of Trent. But the theologians of the reformation, Luther, Carlstadt, Flacius, and John Gerhardt, went back to the Jewish canon, and considered the apocryphal writings as independent and inferior collections. Some Catholic doctors, as Bern. Lamy, have made a distinction between the 1st and the 2d canon, the 1st only being of absolute authority.—The canon of the New Testament was formed upon substantially the same principles as that of the Old. For a century the Hebrew writings were the only Bible the Christians had. The letters of the apostles were publicly read in connection with the ancient Scriptures, and were listened to with the same respect. Gradually such epistles as were addressed to neighboring churches were gathered together in small collections; and later, other works of a historical character, which might recommend themselves by their intrinsic worth or their reputed authorship, were received by such communities as came in possession of them, and were used in public instruction. Many years elapsed before a complete and authorized collection was made. The earliest trace of a collection of New Testament books is found in that which Marcion had in the middle of the 2d century, consisting of 10 epistles of Paul, and a gospel supposed to have been St. Luke's. Half a century later the principal Christian

teachers, Irenæus, Clement of Alexandria, and Tertullian, agreed in receiving 4 Gospels, the Acts of the Apostles, Paul's 13 Epistles, the 1st Epistles of Peter and of John, and the Apocalypse. Respecting the Epistle to the Hebrews, Philemon, Jude, and 2 John, a difference of opinion was raised. At this time, the books were contained in 2 separate collections, one historical, called the *Evangel*, the other epistolary, called the *Apostle*. The next stage in the development of the New Testament canon is indicated by the ancient Syriac translation known as the *Peschito*, which belongs probably to the early part of the 3d century. This contained, in addition to the books acknowledged by Irenæus, Clement, and Tertullian, the Epistle to the Hebrews, and the letter of James; but it omits the Apocalypse, which dogmatic prejudices were bringing into disfavor. An ancient fragment, as old, probably, as the year 200, which was found a century and a half ago in the Ambrosian library at Milan, by Muratori, and is thence called the canon of Muratori, contains a mutilated catalogue of New Testament books then received. In this list are mentioned the Gospels, Acts, 13 Pauline Epistles, 2 Johannean, Jude, and the Apocalypse. James and Hebrews seem not to have been included. 1 Peter is spoken of doubtfully, and words half commendatory are applied to the "Shepherd" of Hermas. The accepted Scriptures of this age were held to be of divine authority. Origen was the first to divide the whole extant literature of the Christians into classes, distinguished as the genuine, the spurious, and the mixed. The genuine were those written by inspired authors, as vouched for by trustworthy tradition; the spurious were those that had no claim to apostolical origin, either from external evidence or internal character; the mixed were such as were of doubtful or contested authority, or had met with only a partial reception. The 4 Gospels, Acts, 12 Epistles of Paul, 1 Peter, 1 John, probably also the Apocalypse, he held to be indisputably genuine and sacred. In respect to Hebrews, James, 2 Peter, 2 and 3 John, and Jude, his mind was in a state of greater or less uncertainty. He appears to waver also in his judgment upon the Epistle of Barnabas, calling it a catholic epistle, and upon the Shepherd of Hermas, which, in one passage, he declares to be in his opinion "divinely inspired,"—so fluctuating in that age was the line that divided the canonical from the apocryphal writings. Origen's opinion, however, was too individual to be received as representing the persuasion of the church. Eusebius the historian, in the early part of the 4th century, prepared a catalogue of the New Testament Scriptures, based upon carefully studied traditions, both oral and written. In his classification the Gospels, Acts, 14 Epistles of Paul, and the first Epistles of John and Peter, are ranked as genuine and universally acknowledged productions of apostles. Among disputed books he mentions the Epistles of James and Jude, 2 Peter, 2 and 3 John, which he

as by the title of catholic Epistles. Other now by all deemed apocryphal, he spurious. To the Epistle to the Hebrews and the Apocalypse, Eusebius hesitates to give a place, being himself inclined, it seems, to receive them into the first class of Scriptures, but deferring to the popular opinion, which was against them. The council of the Greek church, that of Laodicea (A. D. 363), that of Cyril (A. D. 348), that of Nicaea (A. D. 325), and that of Gregory (A. D. 370), agree in accepting all those that compose our present collection, except the Apocalypse. Athanasius alone, and Cyril, included this. The catholic church were by this time generally received, not with entire cordiality. It is clear the canon of the Greek church was not closed at the end of the 4th century. The council of Carthage, which opened the canon of the New Testament to the admission of the apocryphal books, enlarged the canon of the New Testament by the reception of the Epistle to the Hebrews and the Apocalypse, and thus committed, pronounced it closed. The council of Trent (A. D. 1545) decreed (A. D. 1546) that the books of the New Testament be 4 Gospels, Acts, 13 Epistles, 1 to the Hebrews, 2 of Peter, 3 of John, 1 of James, 1 of Jude, and the Apocalypse. Jerome, speaking of Hebrews, says: "I know not the matter whose it is, for it is the property of an ecclesiastical man, and is daily read by being read in the churches." For the same reason he would admit the Apocalypse. The council of Carthage repeated word for word, in the year 397, the rule of the council of Hippo, only ranking Hebrews among Paul's 14 epistles. A few years after a catalogue of the sacred books was made by a decree from Pope Innocent I., which may be regarded as deciding finally the canon of the Latin church. There were still differences of opinion as to the Epistle to the Hebrews and the 2d and 3d of John; but there was room for change. The catalogue was not made up to the period of the reformation, notwithstanding the objections of Cosmas, 535, 550, Isidore of Seville, 636, and Nicephorus of Constantinople, 828; notwithstanding, the criticism of John of Damascus, who does not reckon the Apostolical Canons among the New Testament books, and the judgment of the council of Aix, 789, which would exclude the Apocalypse. The chiefs of the reformation in England, and the two Protestant churches in the Low Countries, in defining which the canonical books were, inclined to follow what they ascribed to be the testimony of the Holy Spirit in the Scriptures rather than the consent of the church expressed in ecclesiastical decrees. Luther's doctrinal test, and applied it to the exclusion of Hebrews, James, Jude, and the Apocalypse. His practice was peculiar to himself. At the same time Protestant theologians have paid little attention to critical studies, and have disguised themselves by efforts to establish the

genuineness of the New Testament writings upon grounds purely historical. The council of Trent, 1545, merely confirmed the canon of Hippo and Carthage, condemned all dissent, and set the seal of oecumenical authority upon the received collection. This mandate of Rome had its effect upon the Greek church, which forthwith canonized the Old Testament apocrypha, and soon laid aside its doubts respecting the Catholic Epistles and the Apocalypse. Thus the great body of Christians, Catholic and Protestant, east and west, with the above exceptions, accepted the same sacred Scriptures. Small sections among the Protestants have dissented. The Socinians, in the 16th century, adopting methods of investigation severely critical, have thrown doubts upon several writings whose genuineness had been left unquestioned for centuries. The same process has been continued to the present day by theologians of different schools, especially in Germany. The Swedenborgians, discarding critical methods entirely, and receiving no dogmatical writing as inspired or canonical, set summarily aside the decrees of councils and the verdicts of scholars, and hold that the 4 Gospels and the Apocalypse are the only Scriptures of the New Testament written under the full influence of the Holy Spirit. They also deny inspiration to the purely narrative and dogmatic writings of the Old Testament, Chronicles, Ezra, Nehemiah, Esther, and the books of Solomon; finding a broad line of distinction between these and the others in their doctrine of correspondences.

**CANON**, an ecclesiastical dignitary who possesses a prebend, or revenue allotted for the performance of divine service in a cathedral or collegiate church. Canons were originally priests who lived in community, appointed to assist the bishop in his duties, and supported by the revenues of the bishopric.—**SECLAR CANONS** are those who, in progress of time, have left off the custom prevalent in monasteries of living a community life, and have the privilege of enjoying the returns of their respective benefices. The obligations of the canons are contained under the 8 following heads: 1, the duty of residing in the place where the church they belong to is situated; 2, assisting at the canonical offices which are celebrated in the church; and 3, attending the meeting of the chapter at the appointed times. They cannot be absent from their benefices for a longer period than 3 months, and are obliged to sing or recite their office in choir. In their collective capacity they are called a chapter, and form the council of the bishop. In each chapter there are dignitaries. The name was originally applied to all the clergy, but was afterward confined to those who were connected with the cathedral church, or to specially privileged churches.

**CANON**, in music, a species of vocal composition in several parts, in the form of a perpetual fugue, in which the voices begin at intervals, one after the other, so that each voice sings the strain of the preceding one and all

sing different portions of the melody at the same time. It differs from the ordinary fugue in requiring that the subject be repeated by each part.

**CANON**, a Spanish word, signifying a tube, flute, or pipe, now in common use in the territories bordering the Mexican states, to designate the deep ravines, or gulches, worn in the hills and mountains by descending torrents of water.

**CANON LAW**, the public and general code of laws of the Catholic church. This church claims to be a perfect visible society, containing within herself all that is necessary for a complete and independent organization. Hence she has her own rulers, rights, and laws. Some of these laws given by Christ himself or by the apostles in his name, are held to be immutable; others have been promulgated by the ordinary ecclesiastical authority, and can be modified or abrogated by the power whence they derive their force. The discipline or practice of the church is therefore partly unchangeable and partly changeable. The changeable discipline, deriving its origin from the ordinary ecclesiastical power, has been different in various times and places. An immense organization extended over the face of the earth must of necessity, while retaining on all essential points the same practice and laws, admit in minor things of those local differences which are required by circumstances. Hence, beside the general law of the church, there are in every particular country peculiar and local rights, customs, and practices, which form what is called the code of particular or national churches. These, however, are subject to the supreme authority, which can at any time annul them, should such a course be judged expedient or necessary. Thus, beside the general law of the church, Roman Catholics in the United States are regulated by the decrees of the councils of Baltimore and of the provincial councils held in the different provinces which have been approved of by the competent authority.—There is also another source of difference in ecclesiastical polity. From the very beginning the eastern and western churches, although agreeing in the same faith and in the observance of the same moral law, and looking upon each other as integral portions of the same church, have yet observed on many points a totally different ecclesiastical discipline. This state of things continues to the present day, and the oriental churches in communion with Rome retain their own liturgy, and their peculiar observances. Hence, the canon law of the Latin or western church is different in many points from that of the Greek or eastern.—The divisions of ecclesiastical law can be marked as follows: 1. The general law of the church, binding all her subjects of all nations and countries. 2. Laws peculiar either to the oriental or Latin church. 3. Laws that are observed by only one particular or national church, belonging to either of these two divisions. 4. Diocesan regulations which have no force out of the bishop-

ric for which they are made.—Canon comprises the general laws for either of churches, eastern or western. Thus the canon law of the oriental and of the Latin church. To the knowledge of this canonist must unite an acquaintance with the particular laws and customs of his own province, beside that of the statutes of the diocese to which he belongs, in order to apply his general rules and principles to practical cases which may fall under his jurisdiction. The authority whence ecclesiastical laws derive their force, is held by Catholics to be vested primarily and principally in the vicar of Christ. General councils possess the same authority. These consist of all or of the greater number of the bishops of the church. The decrees of a legatine council, that is, one presided over by a pope either personally or through his representative, when ratified by the same authority, are binding over the whole church. These two fountains of authority from which all laws derive their vigor. Patriarchal and provincial councils legislate merely for the particular of the church under their jurisdiction, their legislation being subject to the approval or rejection of the pope. Bishops have the power to make laws or statutes for their own dioceses; these are sometimes promulgated in synods, which are composed of the priests of the diocese.—As the discipline of the church has not always been the same, it has been and is different in different times and places, so, too, canon law has not been uniform. Many regulations which were of force have been subsequently modified or totally abrogated. Hence the chief difficulty in the study of canon law is to discern that which is in force and that which has fallen into disuse.—The laws of the church have for the most part embodied in collections. These have naturally been modified as the laws themselves have suffered changes. The history of canon law is a narrative of these modifications. For some time after the death of the apostles, there was in all probability no written collection of laws. The saints who lived during this period had vividly in their minds the decrees and teachings of the Lord, who had conversed with the Lord. In the course of time, unruly and rebellious spirits began to manifest themselves, and discipline suffered many serious violations. As these occurred, decrees were enacted either to punish the transgression or prevent its recurrence in the future. These decrees generally were confined to the locality in which the crime had been committed, and by degrees, through the influence of similar circumstances, were adopted by the whole church. Thus, in the early centuries, many new regulations had been introduced, and the primitive discipline had been more or less modified. This led to the necessity of making a collection of the new laws, so that all might know

port, and thus uniformity, at least on the principal points of discipline, might be secured. The first collection we meet with is composed to have been promulgated either at the end of the 2d or the beginning of the 3d century. It is called that of the *Canones Apostolici*, or "Apostolical Canons." This name is given because these laws were represented as having been promulgated by the apostles. This, however, is not true of them, at least as they appear in this collection; for they bear the marks of a development of organization not existing in the apostolic times. Most probably, during the 2d century, the rules given by the apostles for the guidance of the faithful began to be committed to writing. By degrees new laws were added to them, and the collection thus gradually assumed its present form, retaining the name to which, in a certain sense, it was originally entitled. Whatever may have been its origin, it represents faithfully the discipline of the eastern church toward the latter part of the 2d and commencement of the 3d century. All, however, did not agree as to the contents of the canons; the Roman church recognized only the 50 which had been translated into Latin by Dionysius Exiguus; the eastern church, after the council in Trullo, in the 6th century, received 85.—The work called *Constitutiones Apostolicæ*, or "Apostolical Constitutions," is intimately connected with the collection of canons. It is proved by Beveridge that it appeared toward the end of the 3d century. It does not throw any new light on the discipline of that period, as it agrees on all points with the canons.—The next collection that we meet with in the East is that which was produced in the council of Chalcedon, in the 5th century. It was called the *Codex Canonum*. It seems to have contained originally the canons enacted in the general council of Nice, and in those of Ancyra, Neo-Cæsarea, and Gangra. These 3 councils, although not œcumenical or general ones, had obtained great authority throughout the whole eastern church, and their enactments were universally adopted. In course of time the *Codex* was enlarged by the addition of the canons of a council held at Antioch, and of those of the council of Chalcedon itself, and lastly of those adopted in the next general council held at Constantinople. These were the principal collections of canon law in the early centuries.—In the West there seems to have been no collection of this sort made before the council of Nice. Custom, the decrees of the bishops of Rome, which were issued as occasion required, and those of particular synods, were the basis of ecclesiastical legislation during the first 3 centuries. The canons promulgated at the council of Nice were translated into Latin immediately after the celebration of the council, and were received in the western church, together with those enacted a short time afterward at Sardica. After some time 2 Latin translations appeared of the *Codex* which was used at Chalcedon; one was called *Isidoriana*, or of Isidore; the other

*prisca*, or ancient. In reality, then, up to the 6th century there was no regular collection of ecclesiastical laws in the western church. This want was at that period supplied by Dionysius Exiguus, a learned monk, who published a celebrated collection, which has ever since borne his name. It contained the principal points of the legislation of both branches of the church: the 30 canons of the apostles, then those of Nice, Ancyra, Neo-Cæsarea, Gangra, Antioch, Laodicea, Constantinople, and Chalcedon, translated from the Greek; the 21 canons of Sardica, from the Latin original, together with 138 enacted in different councils of Africa. These formed the 1st part. The 2d embraced the decretals of the popes Siricius, Innocent I., Zosimus, Boniface I., Celestine, Leo the Great, Gelasius, and Anastasius II. These decretals were letters sent by the popes to different bishops or churches, containing those decrees which they deemed necessary for the maintenance of discipline and the good of religion. These, as is evident, formed no unimportant part of church law. To the above mentioned were afterward added the decretals of the popes Hilarius, Felix II., Simplicius, Hormisdas, Symmachus, and Gregory II. The collection of Dionysius thus augmented was presented in the 8th century to Charlemagne, by Pope Adrian I., when the former came to Rome. Adrian did not give it any new public authority; yet from the fact of his having presented it, and from the *quasi* sanction thereby bestowed, it acquired great importance, and was called emphatically the *Codex Canonum*, or code of canons. Such were the principal documents through which access could be had to the knowledge of ecclesiastical legislation, during the first 9 centuries of the Christian era.—Thus far the science of ecclesiastical legislation had advanced in a regular and more or less uniform way. The churchmen had copied the forms of the old civil lawyers, and many made ecclesiastical polity the study of their lives. With the destruction of the western empire, and the universal subversion of all the ancient landmarks of civilization and learning, the church law had to undergo some of the calamities of the age. The barbaric rulers often brought charges against leading ecclesiastics, either for the purpose of confiscating the property of the church, or of revenging the condemnation of their vices; and as the knowledge of canon law had shared in the decline of all science, the churchmen were left unprotected, from a want of acquaintance with laws which would have extricated them from their difficulties. A new collection was therefore required, and did in fact appear, but unfortunately the real erudition of the work was tainted by an inexcusable spirit of imposture on the part of the author. He gave himself a feigned name, that of Isidore Mercator (merchant), or Peccator (sinner). It is not very clearly known who he really was. The most probable opinion seems to be that his real name was Benedictus Levita, or the Deacon. If this be

true, Isidore lived at Mentz in the 9th century. The documents of which this collection was composed can be divided into 8 classes. There were some perfectly genuine, and attributed to their real authors; next, others substantially so, but published under the name of popes or councils to whom they did not belong; others, again, were altogether spurious, and perhaps invented by Isidore himself. Yet even this last class contained only in legal form what already existed in the discipline and immunities of the church. All the evil done by Isidore was done to erudition and history, not to the discipline of the church, which remained the same as before. The English bishop, Beveridge, after much erudite and patient toil, discovered that all the decrees or letters invented by the impostor were in reality nothing but tissues of passages selected from the canons of councils, epistles of popes, and works of ecclesiastical writers, especially of the 5th and 6th centuries. The age in which Isidore lived was not one in which a historical fraud was likely to be discovered. He was everywhere held in honor, till on the revival of letters the new light shed upon this branch of criticism led at first to doubts as to the genuineness of parts of his work, and afterward to the discovery of his imposture.—During this time the collection of John Scholasticus, who flourished in the 6th century, was the principal one in the East. Photius revised it, and added many important laws, and it yet remains the basis of the legislation of the Greek church. Up to the 13th century the principal collections in the West were those of Burchard, Ivo, and Cardinal Deusdedit. They added nothing new to the preceding collections; the troublesome times in which they lived did not afford much liberty for new legislation, or leisure for the study of ancient documents. At last, however, the light dawned, sciences and literature began to be cultivated, and Europe again appreciated the benefits of mental improvement. To the 12th and 13th centuries belongs the honor of having initiated this better state of things; then commenced in reality the revival of letters and civilization. Law was one of the sciences which seemed to meet with most favor in the new order, and formed one of the most important branches of study in the rising universities, especially in that of Bologna. The civil law of the Roman empire became the subject of profound and toilsome investigation. It was natural that in the mediæval society on which the church exerted so powerful an influence, her legislation should be an object of the research of the student, and that canon law should thus become a science to which persons were to devote themselves exclusively. The new state of affairs called for a new collection, which could be used as a class book. Gratian, a Benedictine monk, a native of Tuscany, undertook the task, and published in 1151 his *Concordantia Discordantium Canonum*. This was composed of various texts of Scripture, of the *Canones Apostolici*, of the decrees of general and partic-

ular councils, of the of  
of extracts from the writ of the  
of the enactments of the civil  
empire, or of the F It  
ward the title of *Decretum*  
now known. It lab defect of its time, was knowledge and cri many spurious do  
most part, taken from the It cannot therefore be relie received any public approbation of the  
A spurious or false canon re authority from the circumstance been incorporated in the *Decretum*.  
its faults, however, it is a truly great wonderful work, considering the age it appeared. Gratian is the father of  
of canon law, the bold pioneer, who courage to penetrate this pathless decrees, canons, decretals, decisions, and instructions, to mark out some well-defined points, and to establish certain signs, to guide posterity in their way.—In more recent times, when general attention had been called to the inaccuracies of the *Decretum*, many attempts have been made to correct it. Antoninus Augustinus, a learned canonist of the 16th century, devoted a great deal of time and pain to this object. A commission was appointed by Pope Pius IV. to attend to this important work, which was accomplished during the pontificate of Gregory XIII. The persons composing it are commonly known under the name of Roman correctors.—After Gratian many learned canonists either published new collections, or improved or commented on those already existing. Among these were Bernard of Pavia, Gilbert and Bernard of Compostella. However, their works lost almost all their importance on the publication of the collection of Pope Gregory IX., which introduced a new era in the science of church legislation. Gregory has been truly styled the Justinian of canon law. He saw the necessity of a more authentic work than that of Gratian, of one which, by receiving the approval of the legitimate authority, should become the public code of the church. He intrusted the execution of this idea to St. Raymond de Pennafort, a learned Dominican friar. He faithfully fulfilled his trust, and in 1234 promulgated the celebrated 5 books of decretals. These embraced all the laws of the church then in force, containing those texts of Scripture which referred to disciplinary matters; the decretal letters of the popes, from Gregory the Great to Gregory IX.; the *Canones Apostolici*; the decrees of the councils, from that of Antioch to the 4th general one of Lateran; together with many passages of the fathers, which embodied generally received customs or salutary regulations. In publishing this collection, Gregory enhanced its value by giving it the approbation of the holy see, and commanding it to be received as authentic in all ecclesiastical tribunals, and in all schools of

Thus, for the first time, was given to the law a code of general church law, stamped with the seal of ecclesiastical approbation.—

Gregory VIII. added, in the 4th year of his pontificate, another book to the 5 of Gregory IX. It contained the canons of the second general council of Lyons, together with the most important decrees issued by himself. It was the 6th book of decretals, and received the authenticity that had been given to the 5th. Such, too, was the collection made by Innocent V. shortly afterward, which embodied various decrees of this pope, together with those of the general council of Vienna. These collections commonly receive the name of *decretals*, though originally called the 7th book of decretals. Next came 2 collections, known under the title of *Extravagantes*, laws, which were, wandering outside of the regular

The first contains the decrees of John XXII., the other those of the popes from Urban IV. to Sixtus IV. These different collections, beginning with that of Gregory IX., form what is called the *jus antiquum*, or ancient law, in contradistinction to the *jus recens*, or modern law.—After the great schism of the West, the general council of Constance, convoked to put an end to that schism, passed decrees for the extirpation of abuses, and recommended the pontiffs to prosecute the good work with vigor; but the many and incessant troubles that distracted the attention of Rome, rendered this extremely difficult. When Luther raised the standard of private judgment, and set at naught the authority of the church, what the pontiffs had so long desired at last became feasible; a general council was convoked, and set to work in good earnest to reform the Catholic body. To this effect many new enactments had to be adopted, and the wise disciplinary decrees of the council of Trent form the basis and principal part of modern canon law. Beside these, there are various bulls and briefs of the popes issued for the most part to execute or to explain more fully the canons of Trent. These are precisely the same documents that were anciently styled decretals.

They are to be found in the *Bullarium*, an important work, first commenced by a Roman lawyer, Laertius Cherubini. He began with Leo X. and intended to bring his work down to Sixtus V., but died before completing it. His son, Angelo Maria, however, finished it. There is also the *Bullarium Magnum*, published by Jerome Mainardi, containing the letters or bulls, from those of Leo the 10th to those of Clement XII. There is another one containing the bulls of Clement XI., another again embracing those of Benedict XIII. The *Bullarium* is yet constantly published, and now has been brought down to the years of the reign of Gregory XVI.—The form of the Roman chancery form also a part of modern canon law. These are 71 in number, and are intended to regulate the business of this important office, to which are confided

the many and weighty questions relative to ecclesiastical benefices. These rules were first established by John XXII. They are in force only during the lifetime of each pontiff, being adopted by him at the beginning of his reign. The decisions of the congregations of cardinals enter also into the present code. They are binding for the whole church when given in answer to general questions, or when especially declared to be so. Lastly, the *concordats* with different princes or governments, which are made in order to regulate those modifications of general legislation that the exigencies of the times or other circumstances may demand, are a prominent feature in the present state of ecclesiastical polity, and are gradually effecting important changes, by making what was before but a solitary exception to become an almost universal rule.—This is the history of canon law in its general bearings on the Catholic church. We have refrained from mentioning those details which have reference to particular provinces or nations. Canon law, in its present state, is almost as voluminous as was the ancient Roman code. While one small volume in octavo contains all the dogmatical decrees on matters of faith, ponderous folios are filled with disciplinary decrees. This is inevitable. A dogmatical decree remains always in force, is never modified or repealed; discipline necessarily undergoes modifications and changes.—The canon law is used, under certain restrictions, in the ecclesiastical courts of England and the courts of the 2 universities.

CANONICA, LUIGI DELLA, president of the public works of Lombardy, born toward the middle of the 18th century, died in Milan in 1844. He was as much distinguished for his genius as an architect as for his public-spirited beneficence. Among his principal achievements are the Palazzo Bellotti and his own sumptuous residence, the Casa Canonica, the theatres Ré, Carcano, and Filodrammatico at Milan, 2 theatres at Brescia and Mantua, and the new theatre at Parma, which, after his design, was built by Bettoli. His most celebrated work is the amphitheatre della Porta Vercellina at Milan, begun in 1805 by order of Napoleon. His labors brought him not only fame, but wealth to the amount of \$700,000, of which he bequeathed \$17,000 to the academy of Milan, the interest to be used for the education of poor artists, and \$85,000 to the primary schools of Lombardy.

CANONICAL HOURS, the different portions of the breviary or divine office in the Roman Catholic and Greek churches, arranged for use at certain hours of the day. According to the original custom, still preserved in some strict monastic orders, matins and lauds should be recited soon after midnight, prime early in the morning, tierce, sext, and none at 9, 12, and 3, vespers late in the afternoon, and compline in the evening. The usual custom is, however, at present, both in the public singing or recitation of the office in choir, and in the pri-

vate reading of it, to say matins and lauds on the preceding evening, the little hours at some convenient time in the morning, and vespers and compline at any time in the afternoon. The office is obligatory on clergymen in the major orders, the members of monastic communities, and those who hold benefices. It is chiefly composed of the psalter, and lessons from the Scriptures and the acts of the saints and martyrs, with hymns, versicles, and prayers interspersed. A great diversity of offices have been and are in use. The one most generally used in the Catholic church of the West is the Roman breviary.

CANONICUS, an Indian chief of the Narraganset tribe, born about 1565, died June 4, 1647, was the firm friend of the English, and especially of Roger Williams, whom, to use the words of the latter, he loved "as his own son to his last gasp." From him Williams obtained, March 24, 1638, the grant of land for his settlement of the future state of Rhode Island. During his life the Narragansets were engaged in several Indian wars, but remained at peace with the white men. Many years after his death, however, under the famous King Philip, they became involved in a war with the English, which resulted in their extermination.

CANONICUT, a small island in Narraganset bay, in the state of Rhode Island. It is fertile, and contains the town of Jamestown. On the southern extremity, which is called Beaver Tail, is a lighthouse. The length of the island is about 8 miles, and its average breadth 1.

CANONIZATION, in the Roman Catholic church, a solemn declaration that a beatified servant of God possesses a special glory in heaven, on account of which he is proposed to the special veneration of the whole church. After the beatification of the deceased has taken place, the principal condition which is exacted, in order to go on with the process of canonization, is that the newly beatified should perform 2 miracles, which must stand the test of a most rigorous examination and be judicially approved by the competent tribunal. After this, several consultations are held, the pope issues the decree of canonization, and a magnificent ceremony takes place at St. Peter's church, at which the pope officiates in person.

CANONSBURG, a post borough of Washington co., Pa. It is the seat of Jefferson college, a flourishing institution with 8 professors, 197 students, and a library of 10,000 vols. Pop. 627.

CANOPPI, ANTONIO, an Italian scene-painter, born in 1773, died in St. Petersburg in 1832. He received his first education from his father, who was employed as civil engineer by the duke of Modena, and after occupying himself for some time with fresco-painting, he was subsequently employed as scene-painter in Venice and Mantua. Compelled to resort to flight at the time of the French invasion, he first betook himself to Vienna and afterward to Moscow, where he was engaged in the decoration

of many palaces, which, however, were burnt in the great fire of 1812. From that time until his death he was engaged as scene-painter of the imperial theatre of St. Petersburg. His most admired efforts in that branch of art were his architectural scenes for Mozart's "Magic Flute," and for "Semiramis."

CANOPUS, a star of the first magnitude in the constellation *Argo Navis*. It is in the end of the rudder, and is 87° from the S. pole. It is therefore a southern circumpolar star, and is never visible in the latitude of the northern states of the Union.

CANOPUS, or CANOBUS, in Egyptian mythology, a water god, represented on vessels of a spherical shape. These vessels were used by the ancient Egyptians to keep the water of the Nile in good drinking condition. The worship of Canopus was superseded under the first Ptolemy by that of Serapis—a Greek inscription in honor of Serapis at Canopus having been discovered, by Mr. Hamilton amid the ruins of Alexandria.—In ancient geography, Canopus was one of the most remarkable towns of lower Egypt, near the most western mouth of the Nile. The name of the town is variously ascribed to the divinity of the same name and to Canopus, or Canobus, the helmsman of Menelaus, who died in Egypt of the bite of a serpent, after his return from Troy, and who was buried on the site of the town.

CANOPY (Gr. *κατασκεύη*; from *κατα*, a gnat), a net spread over a bed to preserve the sleeper from insects. In architecture, an ornamental projection over doors, windows, &c.; also, a hood or covering over thrones, niches, tombs, &c. Canopies are also borne over the head in processions.

CANOSA (anc. *Canusium*), a town of Naples, province of Terra di Bari, S. W. of Barietta; pop. about 8,000. It contains a cathedral of the 6th century, the remains of a gateway near the river Ofanto, of a splendid amphitheatre, and the tomb of Bohemond, prince of Antioch. It was subdued by the Romans 818 B. C., until which time it had been hostile to Rome ever since the Samnite war. It is frequently mentioned in ancient classic history, and is spoken of by Horace in the journey to Brundisium. Herodes Atticus constructed an aqueduct to supply it with good water. The Romans called the inhabitants *bilingues*, as they spoke both Greek and Oscan. The mule drivers of Canusium were noted for their skill, and were always selected by Nero as his charioteers. The remains of the Roman army after the defeat at Cannæ, in the 2d Punic war, took refuge in Canusium. Canusium was on the direct route from Brundisium (Brindisi) to Rome. Remarkable ancient tombs discovered in 1868, in the vicinity of Canosa, and the contents sent to the museum of Naples, were described by Millin (Paris, 1818). They generally contain empty vases.

CANOSSA, a small town near Reggio, in the duchy of Modena, Italy. It contains a castle in which the emperor Henry IV. performed

before Pope Gregory VII. in 1077.

1. **THEODORE**, an adventurer and seaman, born at Florence, about 1807. His father a captain and paymaster in the army; his mother a native of Piedmont, after receiving an ordinary school education, resolved to follow the sea, and made his first voyage in 1819, in the American ship *Albatross*, from Boston, from Leghorn to Calcutta.

From Boston, sailed to various parts of the coast, was shipwrecked near Ostend, and again landed on the east of Cuba, where he fell into the hands of a gang of pirates, one of whom claimed him as an uncle, befriended him for some time, and then sent him to an Italian grocer at Havana, who was secretly concerned in the African slave trade. In a vessel owned by a Frenchman, carrying a crew of 21 scamps of various nations, Canot made his first voyage to Africa, in 1826, landing at the slave factory of Fatick, on the Rio Pongo, Senegambia. During a mutiny on board and helping to suppress it, he saved 108 slaves under 15 years of age, 22 inches high, the young adventurer

in the service of the owner of the factory, named Ormond, but commonly called "John," whom he attended in the capacity of secretary and agent, for 3 or 4 months. His old friend, the grocer of Regla, convinced him of the imprudence of his trade, and sent him a slave schooner, which he successively freighted with 217 negroes, receiving a commission, while the Cuban owners derived from their sale a clear profit of \$41,438. Canot became a favorite with the natives, whose proposals of matrimonial alliance were exceedingly embarrassing. He visited various parts of the neighboring country, in pursuit of an opportunity to study the workings of the slave trade, in which he had determined to engage, by collecting by the aid of the African stock of slaves for his newly established station at Kambia near Bangalang. An English vessel was sent out to him from Cuba, and he was

of which died soon after arriving. Canot was ordered to take his place in command, and accordingly sailed for Regla, but was soon captured by 2 British cruisers after a hard fight.

In the presence of the surgeon and steward of the British cruisers he made his escape in a small boat, with one companion, and reached the coast of Senegambia. In May, 1828, his factory and stock of slaves were destroyed by fire. He afterward made a voyage in a vessel at Sierra Leone, in which he rescued 200 slaves wrested from a trader in the hands of the Portuguese. In June, 1828, he sailed to Cuba, where he remained 8 months. Three more expeditions were made; in the first he lost 300 slaves by a storm; in the last he was taken by the British, and condemned to 10 years confinement in the hospital of Brest, in France, but after about 3 years of confinement he was pardoned by Louis XVIII. He resolved still to pursue his dangerous trade, and he returned to Africa, and was the first to resume the slave traffic at New Sestos, an ancient principality governed by a Bassa

chief. After meeting with various adventures here in his expeditions among the surrounding tribes, we hear of him in 1839 on a pleasure trip to England. He returned to New Sestos and in 1840 shipped to Cuba 749 slaves. He now resolved to abandon his illicit course, entered into partnership with Mr. Geo. O. Redman, a London merchant, and obtaining from an African chief a valuable grant of land at Cape Mount, established there in 1841 a trading and farming settlement under the name of New Florence. He made a trip to New York some time afterward. In March, 1847, New Florence was destroyed by the British, who suspected it to be a slave station, and Canot subsequently removed to South America, where he engaged in legitimate commerce. He resided for some time in Baltimore, U. S., and finally received from Napoleon III. an office in one of the French colonies in Oceanica. A narrative of his adventures, written from his own notes and conversation by Mr. Brantz Mayer, was published in New York, in 1854.

**CANOVA**, ANTONIO, an Italian sculptor, born Nov. 1, 1757, at Possagno, in the province of Treviso, died in Venice, Oct. 12, 1822. He sprang from an ancient family, who, for generations past, had followed the trade of cutting the stones which abound in the hills of Asolano and the adjoining country. Young Antonio was put to the same trade. In his 9th year he executed 2 small shrines of Carrara marble, and the remarkable aptitude which he displayed arrested the attention of Giovanni Falieri, a Venetian senator, who placed him, in 1771, under the instruction of a Bassano sculptor, of the name of Torretti, who, in 1773, removed to Venice. Here Canova surprised his friends in 1774, by the execution of the statues of Orpheus and Eurydice. These were well received, and followed by the group of Dædalus and Icarus, and several other works of art, which enabled the artist to prosecute his studies in Rome, Falieri having obtained for him a pension from the Venetian government of \$100 a year for 8 years. He visited Naples, Herculaneum, and Pompeii, and, taking every opportunity of improving his knowledge of the works of antiquity, he soon produced his great statue in marble of "Apollo crowning himself with Laurel;" but his reputation was not firmly established until the completion of his "Theseus vanquishing the Minotaur." His next undertaking was a monument in honor of Clement XIV.; he obtained the permission of his native country to settle permanently at Rome, where after 4 years of arduous labor, the monument was opened to public inspection in 1787. By 1792 he had completed another cenotaph to the memory of Clement XIII.; and gradually he became so overwhelmed with commissions, that he had to extend his studio, which soon almost covered the whole street. Among the many works which appeared from his chisel, from 1795 to 1797, his groups of Cupid and Psyche standing, and of Venus and Adonis, are

the most celebrated. During the revolution of 1798 he visited Germany, and on his return retired to his native village, where he devoted himself to painting, his picture of the "Descent from the Cross" being especially noteworthy. On his return to Rome, he produced his "Perseus with the Head of Medusa," which by public decree was placed in one of the *stanz*i of the Vatican. In 1802 Napoleon invited him to Paris, where he modelled a colossal statue of the emperor, which was not completed before 1808, and afterward passed into the possession of the duke of Wellington. In 1805 he executed his "Venus Victorious," and in the same year he completed his monument of Christina, archduchess of Austria, erected in the church of the Augustines at Vienna. This is considered the master-work of his monumental productions. He revisited Paris twice, in 1810, when he modelled the bust of Marie Louise, and executed the statue of Letitia Bonaparte, for which in 1819 the duke of Devonshire paid \$6,500; and in 1815, when he removed to Italy some of the works of art which had been carried to Paris by Napoleon. His reception at Rome was brilliant; the pope inscribed his name in the golden volume of the capital, and conferred upon him the title of marchese d'Ischia, and a pension of about \$3,000. For his native village, Possagno, he designed a temple after the model of the Parthenon of Athens and the Pantheon of Rome, of which the foundation-stone was laid July 11, 1819. He executed the bass-reliefs, and a great altar-piece for the interior, which he had begun 20 years before; but his earthly career was drawing to its close. Some of his most popular works were wrought by him shortly before his death, as the group of Mars and Venus, the colossal figure of Pius VI., the Pieta, the St. John, the recumbent Magdalen, &c. Among his later works is a Washington, of colossal size, in a sitting attitude, now in the state house at Raleigh, N. C. In May, 1822, he paid a visit to Naples, where he had undertaken an equestrian statue for the king. On his return, his health became more and more impaired, and he died shortly afterward at Venice. His remains were deposited in the church of Possagno. The same monument which he had designed for Titian, was dedicated to his memory in 1827, in the church de' Frati of Venice, and another monument to his honor was raised by Pope Leo XII., in 1833, in the library of the capitol.

CANOVAI, STANISLAO, an Italian ecclesiastic and historian, born in Florence, March 27, 1740, died there Nov. 17, 1811. Having taken holy orders, he officiated afterward as professor of mathematics at Cortona. In 1788, as a member of the academy of antiquities, he contended for the prize which was offered for an essay on Americus Vespucius. He opposed the common opinion that Columbus was the first discoverer of the new world, claiming that Vespucius one year before him had touched upon the northern part of the continent and had landed in Brazil. His paper gained the prize, but produced much

controversy. He published an Italian translation of Gardiner's tables of logarithms writings, and enjoyed also the reputation of a worthy ecclesiastic. When Alf Canovai waited on him to manifest his spiritual wants.

CANROBERT, FRANÇOIS CÉTA, a French general, born in Brittany. Belonging to a good family, he was admitted to the military school of St. Cyr, and nevertheless enlisted afterward as a soldier; but within 4 years reached the rank of sub-lieutenant. In 1835 he went to Algeria and served as first lieutenant in the 1st regiment of Mascara. Being promoted to a second lieutenant, he distinguished himself in 1837 at the battle of Constantine, and received the rank of lieutenant of the legion of honor. He displayed great courage in many encounters with the Arabs, and made a major in 1842, and lieutenant in 1846. With the 64th regiment of the 1st division he marched against the formidable Kabyles, and forced several tribes of the lower Kabyles to submission, and was made a colonel in 1846. Since the revolution of Feb. 1848, his military career has been rapid. An expedition against Ahmed Sghir, bey of Constantine, had excited several tribes to rebellion, and in 1849 against the Kabyles, he was promoted to the rank of brigadier-general. He made a successful inroad on the Arabs, whose strongholds he destroyed, and added to his popularity among the soldiers by procuring for him the appointment of a general of camp to Louis Napoleon. After the revolution he was one of the commissioners sent to the departments in order to expedite the execution of those who had attempted to resist the new act. In 1853 he was appointed general of division, and in 1854, upon the formation of the army of the east, he was placed in command of the 1st division, set out, March 18, 1855, for the Crimea, and was slightly wounded at the battle of the Alma. The emperor having placed him secretly with the supreme command in case of an emergency, he assumed the command after the resignation of St. Arnaud, at the battle of Inkerman; but shrinking from the responsibilities of a general-in-chief, he transferred his command to Pelissier, May 16, 1855, after which he returned to France, where he was received with great distinction by the emperor, who sent him on a mission to Denmark, Sweden, and conferred upon him the medal of Crimea, and the rank of marshal of France. From the British queen he received the grand cross of the bath, and he received the command of the 3d of the 1st military provinces into which France was divided by the imperial government.

CANSO, or CANSEAU, GUY OF, the strait between Nova Scotia and Cape Breton, leads from Northumberland strait into the Atlantic. Length 17 m., breadth 2½ m.

CANSTEIN, KARL HILDEBRAND, a German, founder of the Canstein Bible society

v. born at Lindenberg, Aug. 4, 1667, in, Aug. 19, 1719. Obligated by illness from the army, in which he had as a volunteer, he devoted himself to publication of the Scriptures, conceiving use of printing since so extensively used own by the name of stereotype. His institution at Halle, first founded by others, has been continued with the access to the present time, having printed at the lowest prices about 5,000,000 of the Bible in the German language, those in the Bohemian language. The from the sales is employed exclusively new editions of the Scriptures, which secure permanent existence to the institution. At his death he left to the orphan asylum of his library and a part of his fortune. A charitable society which bears his name now carries on the work of the Franke institutions of Halle, so called after August Hermann Franke, the founder of the orphan asylum, and of other philanthropic establishments.

CANTABILE, in music, denotes the easy sounds of a melody, in contradistinction to highly elaborated passages. A piece where the melodious element is predominant is called cantabile.

CANTABRIA, a district of ancient Spain, lying on the bay of Biscay, and including, according to some of the earlier geographers, now the provinces of Oviedo, San-Basque, and Guipuzcoa. After the Roman invasion, when the country became known, the name was restricted to the district of Santander and the E. part of Oviedo, which was included in that part of the peninsula known as Hispania Tarraconensis. On the N. the territories of the Autrigones, Varduligi, and Vascones; on the W. the river Salia separated it from the country of the Astures, and on the S. boundary was formed by the Cantabric mountains. The river Ebro (Iberus) runs near the district occupied by the Cantabri.

One of the several tribes into which the Cantabrians were divided. Pliny mentions the Cantabri, of which Juliobriga alone was of any importance.—The Cantabri were a hardy and warlike people, and of all the Iberian tribes they opposed the stoutest resistance to the Romans, and though more than once forced to nominal subjection were never wholly subdued. A portion of them acknowledged the supremacy of Augustus, but the bulk of the tribe preserved their independence among the valleys of their mountains, while others, more than submit to foreign masters, sought to free themselves by their own hands. After their first subjection, 25 B. C., they several times rebelled, and were almost exterminated by Agrippa, P. A., and under Tiberius called forth the vigorous exertions of the empire to keep them in check. Horace celebrates their independence and spirit, and Strabo describes them at length as a fierce people, "savage as wild beasts" and the rudest in the whole peninsula.

They have transmitted many of their characteristics to their descendants.

CANTABRIAN MOUNTAINS, a range in the N. part of Spain, formed by a W. prolongation of the Pyrénées, and extending from that chain parallel with the S. shore of the bay of Biscay, W. to Cape Finisterre. They bear various names in the different provinces through which they pass, the best known being those of Sierra de Aralar, Salvada, Ordunte, Anafia, Sejos, Albas, Peña, Mellara, mountains of Asturias, Sierra de Peñamarella, Mondoñedo, Quadramon, and Tecyra. Some of the summits are rugged, precipitous, and clad with magnificent forests; others are crowned with perpetual snow. The maximum elevation is about 10,000 feet. The mountains are crossed by roads from Pamplona to Tolosa, from Bayonne to Vittoria, and from Burgos to Bilbao.

CANTACUZENUS, JOHANNES, a Byzantine emperor and historian, born in Constantinople about A. D. 1300. He began his career during the reign of the emperor Andronicus, under whom he was first lord of the bed-chamber. He was a relative of the royal family, while his talents gained for him the confidence of the people. Andronicus and his grandson and legitimate successor, Andronicus II., were not altogether harmonious. A revolt of the grandson was the result, which was temporarily settled by his being admitted as a colleague to the throne. Three years later, in 1328, a fresh revolt broke out, and Andronicus I. was compelled to abdicate. Cantacuzenus had attached himself to the victorious heir in the outset, and therefore retained under Andronicus II. the honors he had before enjoyed; he was also made generalissimo of the Byzantine forces. Meanwhile the distracted state of the empire during the revolt had furnished occasion for the incursion of the Ottoman Turks, which gave Cantacuzenus an opportunity to display his military skill. He was unsuccessful against them, but rendered valuable service to the empire in reuniting to it Lesbos and Ætolia, and bringing to an honorable termination the piracies of the Genoese in the Ægean. The emperor, dying in 1341, left his son, John Palæologus, 9 years of age, to the guardianship of Cantacuzenus, who soon aroused the jealousies of the empress-mother, Anne of Savoy, and to save his life he assumed the purple at Adrianople in 1342. The civil war which resulted was at first amicably concluded by his admitting his ward Palæologus as the colleague of the throne, and giving him his daughter in marriage. But the jealousy of the empress-mother raised a new sedition in 1353. Cantacuzenus abdicated, and retired to a monastery; where he devoted himself to literature, and produced a history of his life and times, from 1290 to 1360, in 4 books, printed in Paris in 1645 in 8 vols. folio, in the collection of the Byzantine historians. He also wrote several theological works, among which is a defence of Christianity against Mohammedanism, which drew from

Pope Gregory XI. a commendatory letter. Cantacuzenus ended his days in his monastic retirement, as did also his wife, who had retired to a convent on his abdication. It is not certain in what year he died.

CANTAGALLO, a town of Brazil, in the province of Rio de Janeiro, inhabited by Swiss settlers. The town was formerly rich in gold mines, which are now exhausted.

CANTAL, an inland department of France, mostly formed of the S. part of ancient Auvergne. It is nearly covered with mountains of volcanic origin, the highest summit of which is the Plomb de Cantal. The climate is severe, the snow generally lying on the mountains for several months together. Chestnuts are the staple article of food for many inhabitants, who live also on buckwheat, rye, and potatoes; the wealthy classes alone use wheat. The agricultural portion of the department is on a level plateau between Murat and St. Flour; very small parcels of arable land being found in the mountainous region. The declivities of the mountains present fine pastures and meadows, where large herds of cattle are kept during the summer. Large quantities of butter and cheese are produced. There are a few factories of coarse woollens and linens, coarse lace, copper and brass, paper-mills, &c. Many natives of the department annually emigrate in search of employment. These are generally known as Auvergnats, and distinguished by industry and a saving disposition. Pop. in 1856, 247,665.

CANTALUPO, a town of Naples, province of Sannio or Molise, memorable for a French victory over the Neapolitans in 1798, and for a destructive earthquake, in which many lives were lost, in 1805.

CANTATA, a somewhat elaborate vocal composition, ordinarily written for a single voice, with a thorough bass, and comprising recitative and air. Its invention has been ascribed to Barbara Strozzi, a Venetian lady, in the 18th century, and also to Giacomo Carissimi, pontifical chapelmaster, about 1650. It originally assumed the form of an opera, with voice parts and accompaniments of violins and other instruments, but was subsequently restricted to a few melodies, interspersed with recitative, and adapted to a single voice.

CANTEEN (Fr. *cantine*), a small wooden or tin vessel, used by soldiers to carry liquors, cooked victuals, &c.; also a little coffer or chest for holding an officer's eating and other utensils; and, lastly, a public house licensed in British garrisons for the use of the soldiery.

CANTEMIR, DEMETRIS, hospodar of Moldavia, born Oct. 26, 1673, died Aug. 23, 1723. His father, Constantine, held the same office from 1685 to 1693, and his brother, Antiochus, from 1695 to 1701. Demetrius having spent the early part of his life in Turkey, where he acquired not only a high reputation for literary attainments, but also for military and political ability, assisted in the overthrow of Bassaraba, the hospodar of Wallachia, and could only be

prevailed upon by the Turkish to become hospodar in his place, by way of eventually becoming ruler also of his former country. He entered upon his office Nov. 1710, but Turkey having disappointed him in these anticipations, and the Russians being successful in their first expedition into Moldavia, he concluded, April 1713, a treaty with Peter the Great, by which Moldavia was to become an independent principality under the protectorate of Russia, and Demetrius to be the hereditary sovereign, to furnish to the czar's expeditions against Turkey a contingent of 10,000 men. This enterprise, however, was not successful, and the czar was forced to retreat, but demanded the surrender of Demetrius, who followed him to Russia, where he received extensive estates in the Ukraine, with the right of sovereignty over them, and with the rank of a prince in the Russian empire. He was also made privy councillor, and in 1720 accompanied the czar on his expedition to Persia, but illness compelled his return. He aided in the establishment of the academy of St. Petersburg, and was one of the kindred institution at Berlin. He was proficient in 11 languages, and the author of many works on Turkey, Moldavia, and the Mohammedan religion, the best of which is his history (in Latin) of the rise and decay of the Ottoman empire.—**CONSTANTINE DEMETRIS**, a learned scholar and statesman, son of the preceding, died in Constantinople in 1709, died in Paris. He was carefully educated in St. Petersburg, and took for some time a prominent part in the political affairs, officiated as Russian ambassador at various courts of Europe, and gained much credit by his diplomatic, but still more by his literary achievements. Among his most notable works are his Russian translations from the classics, and 8 books of satires, which exerted a powerful influence on the development of Russian literature. Many of his works have been translated into French and English.

CANTERBURY, a city of Kent, in the south-east of England, on the river Stour, 55 m. by road, 81 m. by rail from London. The city has no important manufacturing position. It is one of the richest of the rich agricultural county of Kent, and a large quantity of produce is disposed of here. A local trade is also carried on with the surrounding district. Among the public buildings, beside the churches and the charitable institutions, are the guildhall, market place, corn and hop exchange, and the public museum. There is a cavalry barracks, and a city. Its principal celebrity is derived from its historical associations, and from its position as the metropolitan see of all England. The city is mentioned in the time of the Romans, with the name *Durovernum* (from the ancient *Duro*, a river). It was the capital of the kingdom of Kent, and it was here that Augustus the First, Ethelbert and 10,000 of his Saxons, were buried in the cathedral, which was restored and enlarged during the present century, and now pre-

st beautiful interiors in England, was in 1180. The great tower is of remarkable height. The windows are of painted glass, and colors are exceedingly rich. The length of noble structure is 514 feet, extreme breadth 11 feet. The crypts beneath are considered to be the finest in England, and contain several chapels. The cathedral was founded by Archbishop Lanfranc, completed by Anselm, and consecrated by Archbishop Corbel, in presence of Henry I. of England, David, king of Scotland, and all the English bishops. Augustin was the first archbishop, and died here between 604 and 614. The celebrated archbishop, Thomas à Becket, was murdered before the high altar in 1170. There are numerous monuments in the cathedral; among others those to the memory of Henry IV. and of the Black Prince. There are several other fine old churches in Canterbury, one of the most interesting of which is St. Martin's. In St. Dunstan's the head of Sir Thomas More was found in 1835, which had been buried by his daughter. There are also various architectural relics of past ages. One of the most interesting of these, the great Augustin monastery, long used as a brewery, has been redeemed from its modern uses by the munificence of a private individual, Mr. Beresford Hope, who purchased it, and presented it to the church as a missionary college, defraying the expense of the restorations and enlargements. There are several educational establishments in the city; the grammar-school, an endowed school attached to the cathedral, the national British and infant schools, a blue coat and a gray coat school. There are also numerous charitable institutions. There is a fine hospital. By the liberality of another private individual, Alderman Simmonds, a field, called the Dane John, containing a high mound, was laid out, and converted into a very pleasant garden for public use. The borough of Canterbury is governed by 6 aldermen, 1 of whom is mayor, and 18 councillors, and returns 2 members to the house of commons. Pop. in 1851, 18,398.

**CANTHARIDES** (Gr. *κανθάρης*, a beetle), coleopterous insects of several species, made use of in medicine. The most preferred is the *cantharis vesicatoria*, a foreign fly, procured mostly in the southern parts of Europe, but to some extent in all the temperate regions of Europe and western Asia. A species called the *C. vittata*, or potato-fly, is common upon the potato plant of the United States; it is much used as a substitute for the foreign fly, and is by many regarded as equally efficient. It is even adopted in the pharmacopœias as official. Other species, too, are known in this country, and are in some parts of it exceedingly abundant. The potato-flies appear on the plant in the mornings and evenings of August. During the day they disappear in the earth. They are collected by shaking them off into a basin of hot water. They are from  $\frac{1}{4}$  to  $\frac{3}{4}$  of an inch in length, and of a shining golden green

color.—Cantharides are imported from the countries on the Mediterranean, and from St. Petersburg. The Russian flies, which may be distinguished from others by their superior size and peculiar copper hue, are the most esteemed. In the larvæ state the cantharides live in the ground upon the roots of plants. The flies of southern Europe usually swarm upon the trees in May or June, selecting such as the white poplar, privet, ash, elder, &c. The early morning is the proper time for collecting them, when they are in a torpid state, and will easily let go their hold. Persons protected with masks and gloves beat the trees, and the flies fall upon a linen-cloth spread to receive them. They are then deprived of life by being exposed to the steam of hot vinegar. This method of destroying them dates back to the times of Dioscorides and Pliny. When dry they are carefully packed. If kept in air-tight vessels, they will retain their properties for many years; but if exposed, they will soon putrefy, particularly if reduced to powder. For this reason they should be kept whole until wanted for use. Being then powdered and mixed with ointment or lard, they make a valuable preparation for blistering plasters. Care is required in its application, as troublesome sores, and erysipelatous inflammations are apt to follow its use. Internally administered, the medicine acts as a stimulant, principally upon the urinary and genital organs; its use is attended with danger, as it acts in large doses as a powerful and highly irritating poison.

**CANTHARIDIN**, a principle derived from the alcoholic tincture of the cantharides insect. It was discovered in 1810 by Robiquet. When the strong solution is set aside, the cantharidin separates in crystals like plates of mica or spermaceti. These are volatilized by heat and pass off in white vapors, which condense in acicular crystals. Being soluble in ether, it is used in the preparation of blistering papers, and the principle being extracted, the flies are sometimes used to adulterate the genuine article.

**CANTIOLES**, or **SONG OF SOLOMON** (*Shir-hashirim* in Hebrew, the *ασμα των ασματων* of the Septuagint, the *Canticum Canticorum* of the Vulgate), the 4th book of the Hagiographa, and the 1st of the so-called Megilloth, has its name of Song of Songs from the superior beauty of its language and poetry. In a number of dialogues and soliloquies, written in most harmonious verses, it gives a glowing description of the tender, chaste, and faithful love, as well as of the beauty of two lovers betrothed; or bride and bridegroom; of rural scenes among the mountains of Lebanon and Hermon, among the hills and vineyards of Engedi, and in the environs of Jerusalem and Thirza; and of love itself, sweeter than wine, more fragrant than ointments, which cannot be bought, nor quenched by waters, nor drowned by floods. It is ascribed to Solomon, whose palaces, gardens, chariots, horses, guards, and wives are men-

tioned, enhancing by the contrast, the charms of calm rural life, full of song, innocence, and love. In regard to its form, its plot, and the order of its parts, as well as to its subject, it has been variously classified by ancient and modern writers; by Origen, in the preface to his comments, as an epithalamium in the form of a drama, which is also the opinion of Lowth and Michaelis; by Bossuet as a regular pastoral drama of 7 acts, giving the scenes of 7 days, of which the last is the Sabbath; by others as a collection of songs or idyls. Dr. Adam Clarke regards it as a poem *sui generis*, composed for the entertainment of marriage guests. Its canonicity has also been a matter of controversy; it seems to have been in question with the Jews at the time of the Mishna. Theodore of Mopsuestia, the friend of St. Chrysostom, attacked it most vehemently with arguments derived from the erotic character of the book, and was severely condemned for his attacks. Origen, who is said to have written 10 books of comments on the Canticles, containing no less than 20,000 verses, and his admirer Jerome, are among its most prominent defenders, supported by the circumstance that the book is contained in all the Hebrew copies of the Scriptures, in the translations of the Septuagint, of Symmachus the Jew, and of Aquila, and is mentioned in the most ancient catalogues of the church, commencing with that of Melito, bishop of Sardis, who lived in the 2d century, though not expressly by Josephus. Modern criticism has also questioned the authorship of King Solomon, and several Aramaic words, the *yod* in the word David, and the abbreviation of the relative *asher*, &c., have been quoted as evidences against the generally accepted antiquity of the book, though none of these is conclusive. But no subject has excited more and livelier controversies, or has been a source of more learned and contradictory disquisition and scrutiny, than the question of the literal or allegoric and mystic sense of the book. Many modern critics both among Jews and Christians, not unsupported by the opinions of ancient and grave authorities, contend for the literal sense. They also widely differ in the interpretation of the meaning and object of the book. These writers account for its reception into the canon on the ground of its praise of faithful love, of conjugal affection, and the chastity of monogamy, or of a misunderstanding of the collectors. The more ancient opinion, on the other hand, which is alone regarded as orthodox in both church and synagogue, defends the allegorical, religious, and sacred character of the songs. Thus, on the one side the subject is the love of a shepherd, of a youthful king, &c., and the beloved is a shepherdess, an Ethiopian princess, or, according to Grotius and others, the daughter of Pharaoh, wife of Solomon; while, on the other side, love appears as a spiritual affection, as the love of the God of Israel for his chosen but abandoned people, according to the Chaldee paraphrast, the rabbis, and even Luther; of Christ for the church, between the soul of the believer

and Christ, or as the connection between divine and human nature, according to current in the church. Aben Ezra, a philosopher of the 12th century, finds in the book the hopes of redemption for Israel; Keiser, the restoration of the law by Zerubbabel and Ezra; Hug, an allusion made in the time of Hezekiah to the remnant of the 10 tribes to Judah; the love of wisdom; the alchemists, search for the philosopher's stone. Dr. Baum, of Cracow, brings the book down to the time of Hadrian, finds in it the last outburst of Jewish patriotism and love of liberty. The *harai bather* the mountains of Bashan, heroically defended by Bar-Cokeba. The authors above mentioned, who have written upon the Canticles, the names of Le Clerc, Rosenmüller, Eichhorn, J. Wette, Ewald, Robinson, and Stuart, are mentioned, as well as those of Mendelssohn. Dr. J. Mason Good, who have published the most valuable translations. Of those of Jerome one is extant.

CANTIUM, in ancient geography, a tract in Britain which nearly corresponds to the present county of Kent. The inhabitants (*Cantii*) were spoken of by Cæsar as the most civilized of the native British tribes.

CANTO FERMO (It. firm song), a term applied in ancient church music to the chants or melodies sung without accompaniment, or only harmonized with organ. In such compositions the notes are of equal length, and the structure of the music of the simplest kind. After the invention of the organ, the melody was harmonized with skill and effect, and to such improved vocal composition the name of *canto figurato*, or figured singing, was given, to distinguish it from the *canto fermo*.

CANTON, a town of Canton township, the seat of justice of Stark co., Ohio, beautifully situated on an excellent meadow called Nimishillen creek, in the midst of the finest wheat-growing district in the state since the completion of the Ohio and Pennsylvania railroad from Pittsburg to this place in 1852, has increased wonderfully in size and importance. Bituminous coal and limestone are found in the vicinity. In 1852, the town contained 3 iron foundries, 3 woollen and gun-barrel factories, a bank, an academy, and 4 newspaper offices. Pop. in 1853 estimated at from 3,000 to 4,000.

CANTON, a city of China (lat. 23° 7' 113° 14' E.), the chief emporium of the East, and superior in population and wealth to any other native Asiatic commercial city. In regard to the value of its trade, it ranks in the world next to Calcutta. It was, till 1842, the sole point of European commerce with China, and its commercial distinction has been attributed to the advantages derived from this intercourse, but a careful study of its political sources, and of the enterprises

a different conclusion. It is the chief of the commerce of China with Japan, China, and the islands of the lago. The Cantonese are the farmers of sugar estates and mines in through their ingenuity and energy ore found so abundantly in that coun- een rendered available; they are the urers and traders of Cochin China, ra, Sumatra, Borneo, Celebes, and other nds of the eastern seas, we find the four-fifths of whom are from Canton, as chief directors of coffee culture, sole f tin, the cultivators of spices, the idlers among the semi-civilized people terior, and the leading bankers of the cities; they are also the principal f the inter-insular and coastwise trade. as much the case 3 centuries ago as it day. Barbosa saw in 1511 the great Malacca crowded with their junks, th silks, porcelain, saltpetre, iron, ys, and incense; taking in return pep- l, cotton, opium, and various drugs and he great junk fleet, composed of anging from 500 to 1,000 tons burden, es opposite the European hongts at contributes more to the wealth of the the European fleets which anchor at a. The junk fleet bears annually ants to Asiatic continental and in- us. There are several Canton corre- s at Batavia, Singapore, and Bangkok, rth from \$3,000,000 to \$12,000,000. e regard the position of Canton, we , though more remote from the sea northern commercial rivals, Shang- po, and Foo-choo, it is very favorably to take advantage of the monsoons its junks to the ports of S. E. Asia. ion for internal trade is also highly , situated upon the Choo-kiang or er, formed by the juncton of the Pe- d Yuh-kiang. The river Pe flowing the Yuh, or western stream, with fluents, which have deep waters and a rrent, are navigable throughout the tent of the rich provinces of Quang- Quang-tong, of which latter Canton is d, and derives its name, through Eu- rruption of the language, from this although its proper native name is o-foo, or the "Pearl City of Com- The products of the rich valley by the Mey-ling, Yung-ling, Ya-shan, eu-shan ranges of mountains, area q. m., pop. 60,000,000, have no other ut Canton, and before the establish- hanghai as a port of foreign entry, the of the Yang-tse valley and populous lake basin were brought down the r to Nanngan; thence by portage a pass in the Mey-ling mountains, 24 nn-huing, a considerable town at the vigation of the Pe, and thence down u. The natural water ways of the

rich valley which forms the background of Canton are tapped at innumerable points by artificial conduits, forming a net-work of irrigation and water communication, far surpassing any thing of similar character in any other country. The aspect of the landscape, beheld from the fortifications in the rear of the city, is exceedingly picturesque. Far away among the beautiful verdure and shrubbery of the plain, you behold the gilded masts of junks gliding in all directions, intermingled with the pointed roofs of villages and the spires of pagodas. This beauty of distant Chinese scenery does not appear in the approach to Canton, and the traveller who for the first time passes through the great delta or archipelago below the city, is disappointed by the aspect of the sluggish stream, the low mud banks, and the dead treeless level lying beyond. Large foreign vessels must come to anchor at Whampoa, 12 m. below the city, and to this point they are guided by the famous 9 story pagoda of Whampoa. From thence you proceed to the city in a sampan, or "dollar boat" (the name derived from the charge), passing the Boca Tigris, upon which are situated the Bogue forts, which extend their white walls to the summits of the hills on Great Tiger island. About 4 m. from the city is anchored the "boat town," or the 40,000 covered river boats, which are the constant homes of the half million of Tankia, that strange, amphibious, pariah race of China, who are never permitted to enter into cities; who subsist by fishing, and various singular occupations, such as the rearing of myriads of ducks, of puppies, cats, and rats for the epicures of Canton; and who also recruit the piratical sampans, which infest the mouth of the Canton river and almost every portion of the coast. The Tankia fleet is a home for the city's swarm of prostitutes, and it sends forth its painted floating dens to visit the European and American ships. Between this floating city of outcasts and the point of landing at the foreign quarter is the anchorage of the great junks engaged in foreign Asiatic trade. The foreign quarter, with its handsome 3 story edifices, presents a striking contrast to the low, dingy, tent-like dwellings of the Chinese. This quarter comprises about 4 acres of ground, 2 of which, on the water side, are laid out in walks, planted with shrubbery and ornamental trees, in the centre of which stands an English church. The esplanade immediately within the sea wall, which is an agreeable promenade in the cool of the morning and afternoon, is called Respondentia Walk, and is the chief resort for recreation of the European and American residents. The inland half of the quarter is occupied by the factories or hongts and residences of Europeans, whose flags, hoisted daily, display 8 or 9 different nationalities. When a respectable stranger arrives here with letters of introduction, he is generally received and hospitably entertained at the mansions of the merchants, especially the English and Ameri-

can, who have generally commercial and dwelling establishments at Macao and Hong Kong. For the accommodation of the less fortunate European stranger there are a couple of hotels, conducted on semi-European principles; that is, Chinese in service, chamber accommodation, and filth, and European in diet; but to the curious and hardy traveller, the hotel of Acowo affords a far better opportunity for acquiring a knowledge of the people and city than a residence at one of the princely hongas. Though the Cantonese have been represented as being of all Chinese the most hostile to strangers, yet it has been the experience of several intelligent travellers, that a courteous and cheerful deportment has always secured immunity from insult in visiting portions of the city distant from the foreign quarter; and even rambles with ladies in company have been extended without molestation through the country, around the fortifications of the walled city proper. The walls are 80 feet high, 15 feet thick at the base, narrowing toward the top, built of oblong blocks of sandstone, from 1 to 2 feet in length and thickness, though some portions are partially of brick. This circumvallation forms an enclosure 7 m. in extent, and is entered on different sides by 12 great gates; 4 of which are called partition gates, being in that portion of the wall which separates the city proper from the suburbs, or portion accessible to foreigners. The walled city, as viewed from a commanding height outside, is little else than a rusty, irregular, concave plain of tiled roofs, corners of jutting angles and horns, red flag posts in pairs before the mandarins' houses, and towering above all, widely separated, 2 great pagodas. One of these is 160 feet, and the other 170 feet high. There are 124 josh houses, or small temples, in the city and suburbs. The streets, about 600 in number, are narrow and tortuous, and never designed to permit a European wheeled vehicle to pass, as they barely afford a passage for the palanquins borne on the shoulders of a couple of men, the only means of conveyance for those who are not pedestrians. All goods are transported on the shoulders of porters, who are to be found in such immense numbers, and offer their services at such low rates, that the cost of the maintenance of horses and vehicles is evidently unnecessary amid this swarming population, which is estimated variously at 1,000,000 and 1,500,000, and, including the population of the boat town, perhaps exceeds the latter estimate. Each street is generally appropriated to some particular branch of trade or handicraft; one is called Looking-glass street, another Curiosity street, and another Egg street, where the singular spectacle is beheld of millions of eggs, chiefly ducks' eggs, which are prepared for preservation, and form an item in the foreign Asiatic trade, as well as in the home consumption. The proprietors of the various shops are noted for an unusual degree of suavity. When not engaged within, they

are ever seen standing in the door-ways of their establishments, and, in an amusing jumble of mongrel English and Portuguese, most pertinaciously solicit the attention of the passing European. The Cantonese shopkeeper extends a liberal hospitality to his customers; he always has a refreshing cup of tea to present, wine and other refreshments; and if his civilities and largesses fail to secure a purchase he parts with his visitor with the same unfailing politeness with which he received him. This disposition marks the Canton trader in all parts of Asia. Provisions of all kinds are abundant and cheap in Canton; and few localities can compare with it in point of salubrity. The innumerable children that encumber the narrow pathways, and crowd almost every canal boat, attest the wholesomeness of the climate. This swarming life seems to flourish amid an astonishing amount of dirt; the thousands of women who wade in the filthy river mud at low water, in quest of various mollusks have each generally a child suspended at the backs; and this burden seems to be an invariable appendage of a Tankia woman, when she sculls her sampan along, flaps from side to side the head of her comical-looking little spring. This teeming hive of the human sends forth annually about 40,000 trading adventurers and laboring coolies to different parts of Asia, and of the latter lately to Australia, California, South America, and the West Indies. The temperature ranges from 75° to 90° between June and August, and 50° to 80° in January and Feb. Snow fell in the city in February, but had never before been seen by a living inhabitant. Most of the rain falls in May and June, but in much less quantity than during the rainy season in the same latitude on the Indian peninsula. The S. W. monsoon causes a clear sky, and brings a refreshing and invigorating air from Oct. to Jan. A good deal of complaint of unhealthiness is complained of in the foreign quarter, especially among the ladies; but it must be attributed to their luxurious and heavy European diet, and to the entire absence of suitable exercise.—The first intercourse of Europeans with this city was in 1517, when Emanuel of Portugal sent 8 ships of war to accompany an ambassador, who went to Canton and obtained permission for his government to establish a trading post near the city. This was ultimately fixed at Macao. The English failed in an attempt to open a post there. In 1634 they made another attempt with a greater number of ships; but the expedition was abortive through the opposition of the Portuguese. The perseverance of the English finally gained for them a position in the European trade with Canton, which they still maintain. Their imports in 1822, before the opening of other ports to foreign trade, were valued at \$17,500,000 of British manufactures, \$18,000,000 of colonial produce; with a total value of \$19,000,000, of which \$11,000,000 was of tea. The United States rank

tain in commercial importance at the enterprising merchants of Salem. The operations of this trade, commenced at Canton amid the dangers and vicissitudes of the revolution; and this commerce gave employment to 90,000 tons of goods, taking to Canton \$2,750,000 of American manufactures and produce, chiefly coarse cloths, lead, and ginseng, and returning 1,000,000 of Chinese products, of which 500,000 was of tea.—On May 26, 1841, the British failing to obtain redress for certain wrongs, captured the forts which command Canton and compelled it to pay a ransom of 600,000 to save it from bombardment. In 1856 the British again took possession of the fortifications of Canton. Again in combination with the French, they commenced hostilities against the city, which they captured without much loss, Jan. 5, 1858. An English prison still (Sept. 1858) occupies the city.

CANTON, JOHN, an English savant, born at Gloucestershire, in 1718, died March 1789. Having pursued the study of science with so much diligence as to interest in himself many persons of eminence, he entered as an assistant, for the term of 5 years, the Royal Society at Spital square, London, and at the expiration of that time succeeded to the mastership of the discharge of the duties of which he continued the rest of his life. In 1745, the discovery of the Leyden vial turned the attention of the world to the subject of electricity, in which he made several valuable discoveries, almost equalled only by Franklin. He was the first in England who verified Franklin's hypothesis of the identity of dynamic electricity and lightning. In 1750 he submitted a paper to the Royal Society on the method devised by him of constructing artificial magnets. This secured him an election to a membership in the society, and an award of a gold medal. A paper on the possible elevation of the atmosphere, one on the phenomena of shooting stars, another on the electrical properties of the atmosphere, and another on the variation of the barometer, with appended observations for one year, another on the compressibility of water, and a series of experiments, followed each other in quick succession. This last-mentioned paper brought him, in 1765, a second medal from the Royal Society. The last paper Canton submitted to the society, was to prove that the buoyancy of the sea arises from the solution of its animal substances.

CANTON RIVER (Chinese *Choo-kiang*, or *Choo-kiang*), the lower part of the Pe-kiang, a river of China. It is navigable inland a distance of 300 m., flowing through the provinces of Kiang-tong and Kiang-see. Opposite the city of Canton, and for some distance below, it is studded with small islands, planted with rice and surrounded by a number of forts. It is here very busy with shipping, and deep enough to admit of vessels of 1,000 tons burden. The ships of many nations, however, always discharge

and receive their cargoes at Whampoa, a place 12 m. lower. At a point about 40 m. below Canton the river takes the name of Boca Tigris.

CANTU, CESARE, an Italian historian, poet, and philosopher, born in Brisio, Sept. 5, 1805, educated at Sondrio in the Valtellina, where he taught belles-lettres at a youthful age, resided afterward in Como, and next at Milan until 1848. One of his earliest works, entitled *Ragionamenti sulla Storia Lombarda nel Secolo XVII.* ("Lectures on the History of Lombardy in the 17th Century"), 8vo, Milan, appeared in a second edition in 1842-'44, and contained liberal ideas that brought upon the author the animadversion of the Austrian government, which condemned him to a year's imprisonment. During his confinement he composed a historical romance, entitled *Margherita Pusterla* (Florence, 1845), which has become very popular. His great work, on which his reputation will chiefly rest, *Storia Universale* (Universal History), appeared first in 1837, at Turin. It has been since revised and reprinted at Palermo and Naples, and translated into German. A French translation by Aronx and Leopardi, was published in Paris in 1843. The greatest proof of its merit and success, however, are 8 large editions published in Turin; the last edition, carefully revised by the author, reaching 85 vols. 12mo. The work is divided into the narrative, followed by volumes of documentary history, and various illustrative essays by the author, and concludes with tables and appendices giving a résumé of the whole work. The style is fresh and vigorous, and yet, after the manner of his countrymen, elegant and sustained. Cantu has been a man of great industry and close application, for although he uses the works of others, he is still unhackneyed and free from imitation. This great history is a monument honorable to him and to Italy. He possesses a critical spirit, and is fully up to the time in which he lives, and in his judgments on literary and political characters he seeks to be just as well as independent. The great learning of Cantu is not the only trait that distinguishes him as an original character among many of his countrymen less profound, yet better known than he to the English and American public. He is a friend indeed of liberty, and has suffered as we have seen in her cause, yet he is a devoted admirer and practical follower of the doctrines of the Roman Catholic church. All these traits combined give a peculiar character to his history, and render it both interesting and important. His religious lyrics are found in all popular collections of that kind of poetry, and are much esteemed by his countrymen. Other works, for which he has acquired general esteem, are: *Parnasso Italiano*, *Poeti Italiani Contemporanei, maggiori e minori* ("Italian Parnassus, Contemporary Italian Poets, Major and Minor, &c."), Paris, 1843; *Storia di Como* ("History of Como"), Milan, 1847; *Algisio, o la Lega Lombarda* ("Algisio, or the Lombard League"), Milan, 1846; *Letture giovanili* ("Ju-

venile Readings"), 4 vols., published about the same time, a work devoted to popular education, which has been translated into several languages, and has passed through more than 80 editions; *Storia della Letteratura Italiana* ("History of Italian Literature"). Finally, one of his most popular works is the *Storia degli ultimi Cento Anni* ("History of the last Hundred Years"). It was published first at Florence, 1851, and translated into French by M. Amédée Renée (Paris, 1853). It has since passed through several editions, among which is a recent and revised one issued at Turin. Cantu was obliged to leave Milan at the time of the eventful insurrection of 1848, as he would have been imprisoned had he remained there. He has since returned to Milan, where he is devoted to historical and philosophical studies.

CANTU, or CANTURIO, a town of Lombardy, pop. 5,864. It has had iron manufactures ever since the 10th century, and contains an ancient church, remarkable for a tall and slender belfry, used during the middle ages as a beacon.

CANTYRE, a narrow peninsula of Scotland, forming the southern point of the county of Argyle. It is terminated by a light-house, whose light is seen at a distance of 22 m.

CANUTE THE GREAT, KNUD, or KNUT, the 2d king of Denmark of that name, and first Danish king of England, born in the former country about 995, died at Shaftesbury, in England, in 1035. He was the son of Sweyn, king of Denmark, and accompanied his father in his victorious campaigns in England. Sweyn, having proclaimed himself king of England, died in 1014, before his power was established, and appointed Canute his successor there. The latter was immediately driven out by Ethelred, the representative of the Saxon line, and fled with 60 ships to the court of his brother Harold, king of Denmark. Harold enabled him to collect a large fleet in the north to prosecute his cause in England. He invaded that country anew in 1015. He fought many battles with Edmund Ironside, who had succeeded his father Ethelred, in 1016, and was finally victorious at the battle of Assington. After this battle, Edmund and Canute agreed upon a division of the kingdom. To Canute were assigned Mercia and Northumbria, while the Saxon prince preserved West and East Anglia. By the death of his brother Harold, he obtained the crown of Denmark (1016). In the same year, and but one month after the ratification of the treaty of partition, Edmund died, and Canute became sole king of England without farther resistance. He refrained from murdering the children of his late rival, and sent them to his half brother, Olave, king of Sweden. He put away his wife, Alfgive, the daughter of the earl of Northampton, and espoused Emma, the widow of Ethelred the Saxon monarch (1017), on the condition that their children should succeed to the throne of England. He made the greatest exertions to gain the affections of his English subjects, to whom his Danish origin was no recommenda-

tion. He accordingly disbanded his Danish army, retaining only a body-guard. He endeavored to blend the 2 races as far as possible, and to induce them to live in harmony with each other. He erected churches, and made donations to abbeys and monasteries on the scenes of former conflicts and massacres. In a witenagemote at Winchester, he compiled a code of laws which is still extant. In this code he denounced those who kept up the practice of pagan rites and superstitions, and forbade the sending of Christian slaves out of the country for sale. Although Canute generally resided in England, he made frequent visits to Denmark. He carried with him on these occasions an English fleet, English missionaries, and English artisans. He promoted 3 Englishmen to the newly erected bishoprics of Scania, Zealand, and Fionia. In 1025 he was attacked by the king of Sweden and defeated; but in the night, Earl Godwin, at the head of the English contingent, surprised the Swedish camp and dispersed the enemy. His absence from Denmark, and the bestowal of so many dignities in Denmark upon his English subjects, made him unpopular in that kingdom. To appease this discontent, he left behind in Denmark his son Hardicanute, then aged 10 years, under the guardianship of his brother-in-law Ulf (1030). In this year he made a pilgrimage to Rome. He was well received there by the pope John, and by the emperor Conrad II., who gave up to the Danish king all the country N. of the river Eider. From the pope he obtained privileges for the English school established in Rome, and an abatement of the sums demanded from his archbishops for the *pallium*; and from the various princes, relief for all English and Danish pilgrims and merchants, from all illegal tolls and detentions which they had endured on their route to Rome. He returned from Rome to Denmark. In 1028 he made an expedition into Norway, expelled Olave, and restored Hacon who swore allegiance to him. In 1029 he returned to England, and his Danish subjects proclaimed Hardicanute king of Denmark. Canute immediately returned to Denmark, put down the revolt, and executed the traitor Ulf. In 1031, Canute was acknowledged king of Norway, and laid claims to the crown of Sweden. On returning again to England, he allowed his son Hardicanute to share with him the Danish crown. His reign is very important in the constitutional history of Denmark. Canute issued the first national coinage of Denmark, and published the first written code of Danish law, wherein the custom of private vengeance was prohibited. He raised the clergy in their corporate capacity to a separate estate of the realm, and instituted the Thingish or royal guard of 8,000 men. The members of this body were all men of good family, and rich enough to equip themselves at their own expense. From them sprang the Danish order of nobility; they were tried only by their peers, and formed with the king the highest court of

Canute's last campaign was against King of Scotland, respecting the possession of Cumberland, but before the armies engage the 2 kings were reconciled, and great stipulations concerning the tenure of Cumberland were renewed (1033). Canute was buried at Winchester. By Emma he had children, namely, Hardicanute or Canute Hardy, and a daughter, Gunhilda, married to Henry, the son of Conrad II., of Germany, emperor. By Alfgive he left 2 sons, Sweyn and Harold. To Sweyn was given the crown of Norway; Hardicanute retained that of Denmark, and Harold, surnamed Harefoot, took possession of that of England. Canute is most popularly known, not by his extended rule and legislative enactments, but by the familiar story of the monarch, the courtiers, and the disobedient sea.

CANVAS-BACK (*fuligula vallisneria*), a member of the family *fuligulæ*, or sea-ducks, peculiar to North America, and celebrated as the most delicious of all water fowl, perhaps of all birds, without exception; though on that point authorities and epicures differ. The sea and bays and estuaries are the principal haunts of this genus. Sir John Richardson states, that

*fuligula vallisneria*, the canvas-back, *fuligula ferina*, the red-head, and *fuligula rufirostris*, the ring-neck, breed in all parts of the countries, from the 50th parallel to their most northern limits, and associate much on the water with the *anatinae*. The male canvas-back has the region of the bill, the top of the head, chin, base of the neck, and adjoining parts dusky red; sides of the head and whole length of the neck deep chestnut red; lower neck, fore part of breast and back, pitch black; the rest of the back white, closely marked with fine undulating lines of black; rump and upper tail coverts blackish; wing coverts gray, speckled with blackish; primaries and secondaries light slate color. Tail short, the feathers pointed; lower part of the breast and abdomen white;

the same color, finely pencilled with black; lower tail coverts blackish brown, intermingled with white. Length 22 inches, wing 9½ inches. The bill is bluish black; the feet and

are dark slate color, the irides fiery red. The female is somewhat smaller, and is less brilliantly and less distinctly colored than the male. This species is not found in any part of Europe. Its richly flavored flesh is admitted to be superior to that of any other of the genus.

The canvas-back duck returns from its breeding places at the north about the first of November, and during the winter extends its range to the southern parts of the seacoast of the United States. It is not unfrequently shot on the eastern part of the Great South bay of Long island, in Long island sound, on the shores of bays of New Jersey, at Squan beach, Barnegat, Egg harbor, and in the estuary of the Delaware; but, in all these localities, it is but a common duck, in nowise superior to many others, and decidedly inferior to the red-head.

It is only in the Chesapeake bay, about the confluence of the Potomac and Gunpowder rivers, where it becomes itself, the king of all wild fowl. This excellence is attributable solely to the peculiar food which it finds in that estuary, a plant commonly known as wild celery, botanically as the *zostera vallisneria*, or *vallisneria Americana*, which is on no account to be confounded with the *zostera marina*, or common eel-grass. This plant, of which the canvas-back duck is so fond, that it derives from it its specific name of *vallisneria*, grows on shoals, where the water is from 8 to 9 feet in depth, which are never wholly bare. It has long, narrow, grass-like blades, and a white root somewhat resembling small celery, whence it has its vulgar name; although it is unnecessary to say that it has no real connection whatever with that plant. This grass is, in some places, so thick as materially to impede a boat, when rowed through it, by the opposition it offers to the oars. It is on the root alone of this grass that the canvas-back feeds. For these roots the canvas-backs dive assiduously and continually, tearing up the grass, and strewing it on the surface of the water, in long, regular windrows, like hay from the mower's scythe. The duck rises to the surface as soon as he has obtained the reward of his labor, in the shape of his favorite root, which he cannot swallow under water; and, before he has got his eyes well open, says Mr. Wilson—though, with all due deference to the eloquent pioneer of American ornithology, it may be well doubted whether so expert a diver as the canvas-back ever shuts his eyes—is robbed of his meal by the impudent widgeons, or bald-pates, as they are called in America, which never dive, but, being equally fond of the root of the *vallisneria*, depend on their adroitness and agility to rob the industrious canvas-backs. On this account the bald-pates congregate eagerly, as far as they are allowed to do so, with the canvas-backs; who, however, live in a constant state of contention with their thievish neighbors, and, being by far the heavier and more powerful fowl, easily beat off the widgeons, who are compelled to retreat, and make their approaches only by stealth at convenient opportunities. With the canvas-backs also associate the red-heads, the scaups, or, as they are called in the Chesapeake, the black-heads, and some other varieties, with which they feed on terms of amity.—The excellence of the flesh of the canvas-backs causes them to be much sought after for the market, but in the waters which they frequent they are so strictly preserved by the real sportsmen, who abound in that part of the country, and have obtained the control of most of the shores, that the worst methods of poaching are prohibited. The canvas-backs will not fly, like geese and many of the species of ducks, to decoys; and the anchoring of batteries on the feeding flats, and the sailing after the birds on their grounds with boats, are not permitted under any circumstances, which has preserved

thus far this delicious fowl from extermination. The ordinary mode of killing them is by shooting them on the wing, from behind screens, or blinds, as they are termed, of reeds, arranged on the projecting points of land, over or in the vicinity of which the fowl are compelled to fly in going up and coming down the bay, to and from their feeding grounds. The velocity at which they fly, as well as the height of their course, renders it extremely hard to hit them; and a great allowance must be made in taking aim, in order not to shoot far behind the object, which will surely be the case if the sight of the gun be laid directly on the passing fowl. Add to this, that the feathers on the breast of this duck, as of many others of the family, are so closely compacted together, of so thick and elastic texture, and so matted by the aid of the oil from the gland in the rump with which the bird lubricates them, that any ordinary shot, striking on the breast, as the fowl comes toward the shooter, will make no more impression than it would on the breastplate of a French cuirassier. The best and most deliberate fowlers, therefore, when they have time to do so, let the flights pass, and then shoot them with the grain of the feathers. A remarkable propensity of these birds is to be attracted, with a most singular and insatiable kind of curiosity, by the appearance of any unusual sight on the shores; and anything of this nature will induce them to leave their feeding grounds, and swim in great flocks of thousands together, perfectly fearless, or rather reckless, to the places where men lie for them in ambush. It is said that the scaup, or black-head, can be allured in this manner more easily than the canvas-back; and that the red-heads and widgeons, when they are alone, cannot be deceived at all, though, when in company with the others, they will fall into the same error, and accompany the flocks to their own destruction. Advantage has been taken of this habit to ensnare the unwary birds to their ruin, by a system which is called toling. It is thus practised: A long range of screens is set up along the shore, within a few yards of the water mark, behind which the shooters lie concealed, with small openings at intervals to permit the egress and ingress of a small cur-dog, the more like a fox the better, and so also the odder his appearance and the more remarkable his color, who is taught to run back and forward in front of the blinds, performing all sorts of curious tricks and antics, to attract the attention of the fowl. So soon as this object is attained, they will swim up in a body within easy gun-shot; and so totally are they infatuated and demented by their curiosity, that so long as the shooter holds himself concealed, and the dog continues his deceptive gambols, so long can the stupid birds be drawn up, to receive volley after volley, until they are decimated or destroyed, perfectly regardless of their dead or wounded companions, through which they will continue to advance on the muzzle of the gun. The only thing necessary to be ob-

served in this sort of shoot the flock, which is so deceptive is the effect of shooting water. The plan adopted by the fowlers is, in taking aim, to see the water of the nearest fowl, in a flock of hundreds, clear relief above the sight of the water. The charge will fall into the water, and not into the flock. By good sportsmen, however, it is deemed any other way of shooting canvas-backs than on the wing, from points, is held to be rank poaching. When the river is so cold that the water will freeze, vast numbers of all these ducks congregate at the open air-works, and a fearful slaughter is made of them. The weather at such places; as many, it is said, that 88 canvas-backs having been killed at the discharge of a heavy gun. Wounded canvas-backs are expert divers, and are extremely difficult to recover; wherefore it is usual to be accompanied by a good Newfoundland retriever.

CAOUTCHOUC, India rubber, called by the South American Indians *cauchú*, the milky juice of a number of trees and plants, is found in Brazil, Guiana, Peru, &c., and in the East Indies. The poppy and lettuce, and the euphorbia, afford a similar exudation. The American tree, from which this article is derived, has been variously named by naturalists. It is the *jatropha elastica* of Persoon, and the *serpentina* of Schreber and Willdenow, and the *anensis* of Aublet. The Asiatic tree which furnishes the greater part of the supply for the East, are the *ficus* and *urceola elastica*. The former is one of the noblest forest trees being sometimes 74 feet and its height is not less than 100 feet. In Assam, beyond the Ganges, are found the most extensive forests of it; but the quality of the product is inferior to that of the American tree. The French astronomers sent to Peru were the first to call attention to this article. The tree was afterward discovered by Frisbau in Cayenne in 1751.—The tree is found in Para, S. of the equator, in Brazil, furnishing immense quantities of this article to the world. The trees are tapped in the morning, and during the day, a gill of fluid is received in a cup placed at each incision in the bark. The fluid is turned when full into a jar; and at once to be poured over any piece of wood or a wooden last covered with cloth, of which it takes as much as is required. In a similar manner, it is made by accretion of green layers. As these layers are applied, their hardening are hastened by exposure to the sun and heat of a fire, and thus the article acquires its ordinary black color. When exposed to the sun alone, it is white within, and brown without; when pure, it is white. Complete drying requires exposure to the sun; during this time it becomes soft enough to receive impressions, and is thus ornamented by

collect it upon balls of clay in the bottles and various fanciful figures, in which it is often exported. They also make tubes, which they use for torches. The mould over which the bottles are formed, broken up, is extracted through the

From the custom among the natives of representing their guests with one of the bottles furnished with a hollow stem, to use as a syringe after meals for squirting water into the mouth, the Portuguese gave the name *ringat* or syringe to the gum and alcohol which produces it. The moulded bottles are brought into Para suspended on poles so that they do not touch each other, as for a long time they continue sticky. Beside great quantities of this substance which leaves Para in large quantities, the exportation of shoes alone has for years past to about 800,000 annually. ("Brazil and the Brazilians," by J. Fletcher, p. 553.)—It is not only in various moulded forms, as bottles, buttons, cutting animals, rudely shaped shoes, but is also for exportation, but a method devised by Mr. Lee Norris, of New York, for preserving the juice, as it comes from the tree, and shipping this in air-tight vessels of glass. The liquor is first filtered and then well shaken with about  $\frac{1}{8}$  of its weight of strong ammonia. On being poured on a smooth surface, and exposed to a temperature of 70° to 100° F., the ammonia, removed by the action of the oxygen of the atmosphere, evaporates, and leaves the substance in the form of the object which holds it. In this state a pure white appearance.

It is of a pale yellow, of the thickness of a pencil, and of a sourish odor, and of specific gravity 1.1.

The pure caoutchouc, which separates on being poured, rising like coagulated albumen to the surface, as the mixture of the juice with alcohol is heated, has the specific gravity of 1.1.

This being skimmed off like cream, it is found to constitute about 32 per cent of the juice. It may also be precipitated by hydrochloric acid. On being pressed between folds of cloth and dried, it becomes brittle. It swells by long-continued exposure to boiling water, but regains its form after some time. Alcohol does not dissolve it, but precipitates it from its solution. Oil of turpentine, coal naphtha, and benzene are among its best solvents, as also is a hydrocarbon, called caoutchoucine, obtained by distilling the crude caoutchouc. The addition of acid and alkaline solutions have no effect. On evaporating its solution, the substance is recovered in some instances elastic and in some brittle, so as to serve the purposes of a material which possesses the properties of the rubber; or it is obtained in an adhesive state. By some of the English authorities it is dissolved in linseed oil, in the proportion of 1 lb. of oil to 1½ lb. of caoutchouc.

Booth states that it is not soluble

in linseed oil, nor in the oils of lavender, cloves, and cinnamon.—At the temperature of about 248° F., caoutchouc melts and remains in a sticky condition, unless long exposed to the air in thin layers. It readily inflames and burns with much smoke. Its elasticity is very remarkable; and when a piece of it is stretched, heat and electricity are evolved. If a piece is kept distended for 2 or 3 weeks, its elasticity is lost; exposure to temperature as low as 40° produces the same effect; but the application of a gentle heat immediately restores it. This property is taken advantage of in the manufacture of elastic textile fabrics, woven of the inelastic threads, which are afterward made elastic by heat. At 600° it is partially volatilized, and the vapor when condensed is the oily substance called caoutchoucine, which has been before mentioned as a good solvent of caoutchouc.—According to the analysis of Prof. Faraday, the gum is a hydrocarbon consisting of 8 equivalents of carbon and 7 of hydrogen, which would require the proportion of 87.27 of carbon and 12.73 of hydrogen in 100 parts. The numbers found by him were respectively 87.2 and 12.8. The juice, as obtained from the tree, gave in 100 parts—

Caoutchouc was long known before its most valuable qualities were appreciated. Dr. Priestley refers to it in the preface of his work on "Perspective," printed in 1770, as a substance which had just been brought to his notice, as admirably suited for rubbing out pencil marks, and as being then sold at the rate of 8 shillings sterling for a cubical bit of about  $\frac{1}{4}$  an inch. It was afterward applied to the preparation of varnishes. The chemists soon found how well adapted it was to connect with flexible joints the glass tubes required in their operations; a thin sheet freshly cut being laid around the ends of 2 tubes, and slightly pressed together, adhered, as if it were originally made in this cylindrical form; or, as usually practised, the slip is folded around a single tube, and the 2 ends lapped upon each other being cut with scissors instantly unite: this may then be slipped over other tubes. It came then to be used to render cloths water-proof, and as its properties and those of its compounds with sulphur, for example, were better understood, it was found to be adapted to a multitude of uses. Its elasticity and flexibility were qualities required in many important surgical instruments, some of them of tubular form. The elastic bands and threads found numerous applications in the arts and trades; by the bookbinder they have been used for securing the leaves of books, giving flexibility and freedom of opening to the volumes; and for a great variety of springs they have taken the place of steel. Upon the English rail-

ways the elasticity of caoutchouc in gradually resisting compression, has caused it to be made into buffers, which reduce the jar caused by the railway carriages striking together. In the same way it is used in this country in piles of circular disks for the springs upon which these carriages rest; and a patent has been granted here for laying the rails themselves upon the same material. By reason of its density and flexibility, it is suitable for many of the uses to which leather has been applied; while its imperviousness, and resistance to the action of substances which destroy leather, give it some important advantages over this material. This is particularly the case in the packing of metallic joints to render them steam-tight. In thin sheets it has been used for taking impressions of engravings. In this form it is an excellent material for covering the mouths of bottles, and for other applications requiring the exclusion of air and moisture. In a melted state it makes lutes that are of service in chemical operations; and it may also be moulded and hardened into ornaments of intricate forms. It makes with other ingredients a cement, called marine glue, which is unsurpassed in adhesiveness when applied to join surfaces of wood, and is not affected by moisture. Masts of vessels have been so firmly spliced by its varnish, that when broken, the fracture is always found to be in the whole wood. It has been stated that the timbers of a ship might be more strongly glued together by it, than they are held by bolts. To make this glue, a pound of small fragments of caoutchouc is dissolved in about 4 gallons of rectified coal tar naphtha, the mixture being well stirred. In 10 or 12 days, when the liquid has acquired the consistence of cream, twice its weight of shell-lac is added. It is then heated in an iron vessel having a discharge pipe at the bottom. As it melts it is kept well stirred, and the liquid flowing out is received upon slabs, and thus obtained in the form of thin sheets. It is applied after heating it to  $248^{\circ}$  F., with a brush, being kept sufficiently soft after spreading, by passing iron rollers of the temperature of  $150^{\circ}$  over the surface, as may be necessary, until the joining is made. In England, blocks of caoutchouc combined with other substances have been used for paving stables, lobbies, and halls. The entrance for carriages to Windsor castle is thus paved. Among the most prominent of the numerous other uses of this valuable substance, alone or in combination, may be named machine belting, water pipes or hose, baths and dishes for photograph and chemical purposes, coverings of telegraph wire, boots, shoes, toys, life preservers, clothing, furniture covers, travelling bags, tents, beds, water pails, &c., &c. New uses are constantly discovered for it, as new properties are developed in the various chemical and mechanical modes of treating the article.—For most of the purposes to which it is now applied, it is either uncombined with other substances, or it is in the form of a sulphuret of caoutchouc, or what is called the

vulcanized caoutchouc. To pound, the crude article is first washed and thoroughly cleaned from impurities and adulterations by a series of washings with water, steam, and mechanical action. In the English process, the little pieces are cut and torn with iron teeth in a cylinder of cast iron, which is so small that 100 lb. of caoutchouc make a charge. So much heat is generated in this process, that cold water is used to wash the substance is soon made dry, and then ground dry in another mill with iron chisels, which cut into the mass a network of fine lines for the escape of the confined air, which burst out with frequent explosions. A little quick-lime is worked into it. In other machines it is kneaded and rolled in various ways, and finally a number of balls thus treated are brought together and powerfully squeezed by a screw press in iron moulds, in which being firmly set, they are left for several days. This process is somewhat modified in different establishments. In some the mill is not used, but the pieces are rolled into sheets, from which thin sheet rubber are sliced by the aid of suitable knives worked by hand, and kept wet. The sheets are at once pressed into the purposes to which this form is adapted. In machinery of great ingenuity the threads of any desired degree of fineness are made. If then required to be joined, a cord is made with a pair of scissors, each blade being a fresh surface upon each piece, being brought together and pressed between the fingers, they at once form a perfect joint, provided no moisture or grease has been on the surfaces. As the threads are repeatedly pressed, they are deprived of their elasticity, and between the moistened fingers are pressed so that they are elastic again 8 times. After remaining on the press 8 days, the threads are wound upon bobbins, and are then ready for weaving or for sewing. Threads of various degrees of fineness may be made from 1 lb. of the caoutchouc making a thread 8,000 yards in length. In another machine is divided in 32,000 yards from one pound. It is also made by covering the caoutchouc with threads of silk or other material. In India, caoutchouc threads are knitted with cotton, or linen. The stuff is made by passing a hot iron over it, and by stretching the caoutchouc to shrink and regain its elasticity. Too great extension of the article would be stretched so as to destroy its elasticity, is prevented by making the threads of the warp of the same material as the weft, so that these shall receive the process of Messrs. Aulard and Grenelle near Paris, a thread of any size may be obtained of any size of caoutchouc after being cleaned and made into a paste of the consistence of

macerating it 12 or 15 hours with one its weight of sulphuret of carbon, about 5 per cent. of alcohol is added. It is well kneaded by compressing it through fragments of wire gauze placed in a cylinder, and is then forced through a series of holes at the bottom of another cylinder by threads as they issue from these taken on a web of velvet, from which to another of common cloth, and are allowed to run along for 600 or 700 feet, when they become dry and hard by the evaporation of the solvent, and are received each one in a cup. Another kind of thread is that which is obtained by the vulcanizing process, of which we will be given further on. These, retaining their elasticity, are woven only as they are extended by weights. In their use for making or corrugated fabrics were first produced, the shrinking of the threads drawing the surfaces of the cotton or other material to which they were applied.—The water-proof cloth known in Great Britain from the name of John Mackintosh, are made by coating the cloth on one side with a layer of India rubber varnish; or sometimes 2 strips of cloth coated are laid together and compressed so that they form one body, with the caoutchouc exposed between the 2 parts. The disagreeable odor which these stuffs commonly reflect by the coal-naphtha, turpentine, or other solvent employed to liquefy the caoutchouc, should the natural juice be applied, as from the tree, and its inspissation taken off from the cloth, the dissolving process and its disagreeable effects would be avoided.

The steam from heated aromatic resins and the smoke arising from their combustion when made into pastilles, as also the sulphur mingled with the vapors of alcohol and alcohol, have been used with more success to deodorize these fabrics. They are sometimes immersed in disinfecting solutions for the same object.—Vulcanized caoutchouc is a combination of this substance with sulphur, was first prepared by Mr. Charles Goodyear of New York, to whom a patent was granted in February, 1839. He afterward introduced another process by which lead was introduced, in the form of white lead, into the mixture, the white lead and sulphur being used in preparing paint, 7 parts of the lead to 1 of the latter, and then mixed with the caoutchouc dissolved in some essence. The lead has the effect of rendering the compound more compact and heavy. Perhaps the peculiar chemical properties, for which this compound is so remarkable, are as advantageously obtained by the simpler mixture of sulphur and caoutchouc. The compound of sulphur and caoutchouc is remarkable for possessing a higher elasticity than caoutchouc alone, and retains this at low temperatures, even below the freezing point; neither is this property of the substance being frequently stretched, or exposed to a high degree of heat without

change; at a temperature above 280° F. it is charred, but it will not melt, unless exposed to flame. In its preparation, after the ingredients have been well incorporated together, it is heated in close vessels to nearly its charring point, the effect of which is to give it, beside its more perfect elasticity, a power of resisting the action of the solvents which liquefy the natural product, and also to greatly increase its resistance to the action of acids and other corrosive fluids. Its adhesiveness is lost, so that freshly cut surfaces cannot be made to unite. The combination with sulphur has also been effected by exposing the rubber to the action of sulphurous fluids, as the sulphuret of carbon and the chloride of sulphur. An immersion for 1 or 2 minutes in a mixture of 30 or 40 parts of sulphuret of carbon to 1 of chloride of sulphur, it is found, will serve to vulcanize caoutchouc, this being subjected to the usual high heat. While at this temperature, if compressed into moulds, as those used in forming shoes, the form is retained on cooling. Magnesia also has been applied by Mr. Goodyear, it is said, for the purpose of giving that degree of hardness to the material, which renders it well adapted for the manufacture of fancy boxes, combs, canes, buttons, knife-handles, &c., its appearance and tenacity being like that of horn, but its elasticity has disappeared. Sulphur in the proportion of 1 part to 8 of caoutchouc is probably all that is essential to give the hardness, provided the mixture be exposed to a sufficiently high temperature for a long time. Magnesia and some other matters introduced have the effect to lighten the shade. The heat is applied to the articles buried in pulverized soapstone by the introduction of highly heated steam.—In the different manufactories of this article a great variety of processes have been introduced, and a high degree of chemical skill and of mechanical ingenuity has been applied to perfect the operations. The highest success, as is shown by the superior reputation of the goods even in the English markets, has been attained in the American establishments, the credit of which is due to the untiring perseverance and ingenuity of Mr. Goodyear. The following table presents the U. S. imports and exports of caoutchouc during 1856 and 1857:

	Year ending June, Same period,	
	24, 1856.	1857.
Imp. of manuf. caoutchouc.....	\$97,796	\$139,535
“ unmanuf. “ .....	1,045,576	882,058
Total impa. into U. S. from foreign countries.....	\$1,143,372	\$1,021,593
Re-exported of the foreign import of manuf. caoutchouc.....	\$18,579	\$62,593
Re-exported of the for. imp. of unmanuf. caoutchouc.....	120,802	64,491
Exports to foreign countries of home-made caoutchouc shoes (655,230 pairs).....	427,266	231,129*
Exports of other manuf. of caoutchouc.....	665,002	\$12,267
Total expa. U. S. to for. countries	\$1,232,719	\$770,596

\* 257,202 pairs.

England imported from foreign countries, from Jan. 1 to June 1, 1857, 5,433 cwt. of caoutchouc, and during the same period of 1858, 9,155 cwt.

CAPE, the extremity of a portion of land projecting beyond the general line of the shore.

CAPE ANN, the S. E. point of the town of Gloucester, Essex co., Mass., the N. limit of Massachusetts bay. The whole of the rocky peninsula forming this part of Gloucester is also called Cape Ann, including the village of Squam in its N. E. part. This peninsula is a headland of sienite, which forms low hills, over the surface of which the rock is very generally exposed to view. The lands are strewn with the greatest profusion of bowlders, many of great size; and beds of pure white sand are intermixed with the ledges and bowlders. Valuable quarries of sienite for building purposes are worked most conveniently for shipment. The place is much exposed to the prevalent N. E. storms; but it offers a small, well-sheltered harbor among the rocks, where coasting vessels often take refuge. There are on the shores of this harbor 2 fixed lights, 500 to 600 yards apart, and 90 feet above the water. Lat.  $42^{\circ} 38' 18''$  N., long.  $70^{\circ} 34' 42''$  W. Distance from Boston 31 m., N. E. by E.

CAPE BABELMANDEB, formerly called Jebel-Manhali, is a conical basaltic rock, 865 feet high, on the N. side of the strait of the same name, between the shores of Arabia and Abyssinia, uniting the Red sea with the Indian ocean.

CAPE BÉARN, a promontory of France, on the Mediterranean. On Mount Béarn, which forms its summit, is a first class light-house.

CAPE BLANCO, or OXFORD, near the S. W. part of Oregon territory, is near the mouth of Rogue river on the Pacific coast.

CAPE BOEO (anc. *Lilybaeum Promontorium*) is on the W. coast of Sicily, 1 mile from Marsala. It is the point of Sicily nearest to ancient Carthage, and at an early period became an important naval station. The naval victory of the Romans over the Carthaginians, which put an end to the first Punic war, was gained near this point.

CAPE BOJADOR, of western Africa, is formed by the termination of a range of Mount Atlas, and until doubled by the Portuguese in 1488, had long been the S. limit of European navigation.

CAPE BON, or RAS ADDER, a headland of Tunis, on the Mediterranean, is the northernmost point of Africa.

CAPE BRETON, a British American colony S. E. of the gulf of St. Lawrence, lying between lat.  $45^{\circ} 27'$  and  $47^{\circ} 5'$  N., and between long.  $59^{\circ} 40'$  and  $61^{\circ} 40'$  W.; area 3,120 sq. m. It is divided from the mainland by the gut of Canso and St. George's bay. The island contains some high land, and the coast is well indented with harbors. The Bras d'Or is a remarkable inlet of the sea, which almost divides the island into 2 parts, and occupies a very large part of the insular outline. It is 55 m. long and 20 m. wide, and varies from 70 to 800 feet in depth. In it there is an island

called Boulardrie island, which contains a little Bras d'Or. Beside these sea-water gulfs, there are several fresh-water lakes in the island. Granite is found at the Bras d'Or, gypsum in various parts. Coal in large quantities exists in the island, and upward of 50,000 tons were raised in 1851. A rich iron ore is also found. There are about 64,000 acres of land under cultivation, producing cereals and root crops, with butter and cheese. There is a boundless supply of salt and fresh water fish. The inhabitants are occupied in agriculture and fisheries; they also carry on domestic manufactures of cloth and flannels. The number of vessels built in 1851 was 24, tonnage 2,593, and of boats 468. The value of imports that year was about \$154,000, and of exports \$260,000. Entrances, 476 vessels, tonnage 43,848; clearances, 377 vessels, tonnage 35,570. The vessels employed in the fishery of 1851 numbered 21, tonnage 463, with 83 men; and the boats 654, with 1,200 men. The quantities of fish cured were: dry-fish, 21,458; salmon, 344 barrels; shad, 28 barrels; mackerel, 9,428 barrels; herring, 6,118 barrels; alewives, 53 barrels; while the fish oil obtained amounted to nearly 25 percent. of the quantity furnished by the other parts of Nova Scotia.—The first settlement in the island was made in 1712, by the French, who called it *Isle Royale*, and who constructed 8 years afterward the fortification of Louisburg, on the S. E. coast. It was taken from them by the British colonists of New England in 1745, and is now included within the government of Nova Scotia, returns 2 members to the Nova Scotia house of assembly, and is divided into 3 counties, namely Cape Breton, Victoria, and Inverness. Pop. of both counties in 1851, 27,580; 11,498 of whom are Roman Catholics, 8,968 members of the Free church, 3,452 of the church of Scotland, 2,156 of the church of England; the Presbyterian church of Nova Scotia, 106; Baptists, 581; Methodists, 685; Independents, 73; the rest consisting of other denominations, with a small sprinkling of native Indians.

CAPE CARTHAGE, a promontory of N. Africa, in the Mediterranean. Traces of the ancient city of Carthage are found near it.

CAPE CATOCHE, a headland at the N. E. extremity of the peninsula of Yucatan, Central America. It was on this spot that the Spaniards first landed on the American continent, and Bernal Diaz tells us that within 6 miles of the cape they saw a large town which they named Grand Cairo.

CAPE CHARLES is at the N. entrance of Chesapeake bay, and forms the S. extremity of Northampton co., Va. N. E. of it, on Smith's island, is a light-house with a revolving light.

CAPE CLARENCE is a headland at the N. extremity of Jones's sound, Baffin's bay. It is surrounded by inaccessible mountains whose summits are covered with perpetual snow.

CAPE CLEAR, a headland of co. Cork, Ireland, is on an island of 1,506 acres, with a light-house on an abrupt cliff 455 feet high.

**CAPE COAST CASTLE**, a town and fort of Africa and capital of the British settlements on the coast of Upper Guinea; pop. about 10,000. The town is regularly built, in a well-wooded poorly watered district, and has a damp, unhealthy climate. It exports gold dust, palm oil, and tortoise shell. The settlement is governed by a president of council and subordinate officers. The fort, which is the best on the coast, stands on a granite rock projecting into the sea, and has near it 2 small outposts called Fort William and Fort Victoria.

**CAPE COD**, the sandy peninsula making the S. E. extremity of Massachusetts, and (excluding the neighboring islands) co-extensive with Barnstable co., already described. This body of land, commencing at the line between Plymouth and Sandwich, extends E. about 35 miles, its width beyond Sandwich rarely exceeds 8 miles. It then bends to the N. and gradually to the N. W., extending about 30 miles to Provincetown. The curve still continues around to W., S., and E., enclosing the fine land-locked harbor of Provincetown. This latter portion does not average half the width of the former, and is greatly indented by bays, both on the land and inner sides. The northern extremity is called Race Point. On this there is a revolving light 155 feet above the level of the sea, in lat.  $40^{\circ} 40' N.$ , and long.  $70^{\circ} 14' 48'' W.$  There are, however, many other light-houses upon the cape. The so-called Cape Cod light is on the highlands (highlands), 200 feet above high water mark, in lat.  $42^{\circ} 2' 24'' N.$ , and long.  $70^{\circ} 18'' W.$  This is a fixed light. Cape Cod bay is a body of water included in the arm of the opening into Massachusetts bay on the N. E.—Cape Cod was discovered May 15, 1602, by Captain Bartholomew Gosnold, of the bark *Concord* of Dartmouth, in an expedition of discovery, made principally at the expense of Henry, earl of Southampton, friend and patron of Shakespeare. To the "mighty headland," which he called it, he gave the name of Cape Cod, from the quantity of codfish taken off its shores. The first people landed and spent a day wandering about—the first authenticated visit of whites on the coast of Massachusetts. Captain Gosnold cruised around outside the cape to Buzzards bay, and landing on one of the Elizabeths spent some weeks exploring, and taking in furs, with which he returned to England. The next year, 1603, another English expedition, employing 2 vessels, 1 of 50 and 1 of 26 tons, made the same voyage, passing also along the coast. It continued to be known to the occasional voyagers of this period; but on Nov. 9, 1620, it was especially made memorable by the arrival of the *Mayflower*, which brought to New England the first company of permanent settlers, and the next day cast anchor in the harbor of Provincetown. Here, on the 11th, before the company disembarked, was drawn and signed by the males the since famous compact, by which they became a body politic, subject "to such government and gov-

ernors as should by common consent" be chosen. At that time the extremity of the cape does not appear to have been so entirely destitute of agricultural interest as it has since become. The pilgrims found on the shores patches where the Indians had planted corn, and obtained supplies of the grain. Mention, too, is made of their bringing back to the vessel a boat load of juniper. The lower portion of the cape is for the most part a waste of barren sand-hills, covered only here and there with a little beach-grass; among them are found numerous ponds, by the sides of which a little arable land is occasionally obtained; and along the shores are extensive salt-water marshes. Toward the head of the cape pitch-pine and oak trees of several species form extensive forests, in which the pines predominate. In Sandwich and Plymouth is a wide range still occupied by the wild deer, the only place in Massachusetts in which they have not been exterminated. The cape is more destitute of rocky formations than of trees. Not a ledge raises itself anywhere above the sand, nor is one met with by sinking wells, until passing in a northerly direction beyond the bounds of Plymouth. Boulders are abundant, and often of great size, particularly near the head of the cape. The depth of sand is nowhere known. About Provincetown it is kept in motion by the winds, and its hills are shifting dunes. The curved form of the extremity suggests the possibility of its having been produced by the prevalence and preponderance of the N. E. winds, the heavy surf rolling up the sands upon the shore, and the winds moving them gradually toward the S. W.—Though a sandy district, the cape is no barren waste; its numerous bays furnish many harbors, and about these are pleasant and thriving villages of intelligent and enterprising people. Their chief means of support are navigation, fishing, and the manufacture of salt. These towns are the nurseries of seamen, and have furnished the masters of many of the best ships of the American merchant service. They belong to the class referred to by Edmund Burke in his address to the house of commons in 1774, a class then as now favorably known in all parts of the world: "No sea that is not vexed by their fisheries; no climate that is not witness of their toils. Neither the perseverance of Holland, nor the activity of France, nor the dexterous and firm sagacity of English enterprise, ever carried their most perilous mode of hardy industry to the extent to which it has been pursued by this people."

**CAPE COLONY**, or **CAPE OF GOOD HOPE**, a colony of Great Britain in the southernmost portion of Africa, between lat.  $28^{\circ} 38'$  and  $34^{\circ} 51'$  S., long.  $18^{\circ}$  and  $28^{\circ}$  E. Area estimated by British authorities at 250,000 sq. m., though it does not exceed 200,000 according to the best German geographers. It is bounded N. by the Gariep, or Orange river, N. E. and E. by the Keiskamma, Great Kei, and Kraai, or Grey river, S. E. by the Southern ocean, S. and W. by the Atlantic. Its greatest length from the Cape pen-

insula to the mouth of the Keiskamma river is over 600 m., its breadth over 400 m. The formation of the surface is that of a terraced country rising from the S. coast by a series of parallel chains of rugged and barren mountains toward the broad table-land which extends from the Orange river N. far beyond the tropic. This table-land is marked off to the S. by a mountain range sweeping from lat.  $30^{\circ}$  in a crescent-like form  $2^{\circ} 30'$  S., then E. and N. E., where it connects with the Amatola mountains of Caffraria. Portions of this range are the Roggeveld (rye-field), Nieuwveld (new-field), and Sneeuw (snow) mountains, the highest peaks of which rise to an elevation of 10,000 feet above the level of the ocean. The flats lying back of this girdle of mountains have a hard, clayey soil, without any vegetation except in the vicinity of the Orange river. The 2d terrace (going from N. to S.) consists of the Rough Roggeveld, the Warm (or low) Bokkeveld, the Cold Bokkeveld, and the Great Karroo, a sort of table-land or elevated basin, thinly covered with an argillaceous soil, largely impregnated with iron upon a substratum of rock or gravel. This arid plain, covering an area of over 20,000 sq. m., at a medium height of 3,000 feet, is for  $\frac{3}{4}$  of the year as hard as baked brick, and almost without any vestiges of vegetation. Only in early spring, when the rain, descending in torrents, fills the otherwise empty river beds to overflowing, plants appear with surprising rapidity. The W. descent of the 2d terrace is formed by the Kamis and Tulbagh chain, which begins at the mouth of the Elephant river, in wild and craggy isolated rocks of most singular forms, which, coming more closely together as the range sweeps to the E., at last unite in the compact mass of the Karroo. The S. descent is formed by the Zwarteberge (Black mountains) running nearly 400 m. from W. to E., and by a parallel chain running (under the names of Zwellendam, Uteniqua, and Zitzikamma mountains) from Worcester S. E. to Zwellendam, thence E. about 200 m. to the mouth of the Great Fish river. The average height of these ranges is 4,000 feet; their greatest elevation, 6,500 feet. The 3d or lowest terrace is the coast district, the S. W. corner of which is filled by the rugged and precipitous Table mountain (8,582 feet), while the Hottentot Holland, or Drakenstein range, radiating near Worcester from the Tulbagh and the Zwellendam chains, sweeps in a southerly direction to the E. coast, terminating in Cape Hanglip. Between this range and the Cape peninsula or Table mountains, there extends a broad sandy plain, the Cape flats, from which it would appear probable that in former times the peninsula was surrounded by the sea. The mountains belong to the sandstone formation, resting upon a basis of granite. Where the granite rises above the level of the surrounding country, it gives rise to many streams of water, but otherwise aridity prevails.—Rivers are numerous, but very few of them are navigable. The more important

flowing into the sea on the S. coast are the Breede (Broad) river, the Gauritz, the Camtoos, the Sunday, the Bush, the Great Fish, and the Keiskamma river on the W. coast the Great Berg river, and the Orange or Elephant river. The Orange river (discovered in 1777 by Capt. Gordon, and named in honor of the dynasty of Orange), having a length of 1,000 m., an average width of 1 m., and in the rainy season a depth of 50 feet, flows through the larger part of southern Africa from N. to S. W.; but only on its upper course is it navigable by the colony. The Great Fish river (discovered by the *Infante* of the Portuguese) rises about 100 m. from its mouth. But nearly all the rivers of the colony have the characteristics of arid rivers, drying up almost entirely at the end of the rainy season, leaving only shallow pools of brackish water, and again swelling to a formidable torrent during their courses, which have more to do with deep ravines than river beds, to the capacity. In consequence of these characteristics, most of the rivers are not even suited for the purpose of irrigation.—The coast is indented by several bays, viz.: Table bay, False bay, Algoa bay, and Waterloo bay. The southern coast is full of reefs, and a narrow strait (Lagullas) extends to lat.  $37^{\circ} 30'$ , making the navigation difficult and dangerous. Two-fifths of the soil of the colony is composed of arid ridges and sandy plains; the remainder, a large portion affords excellent pasture for horses and cattle, but is not adapted for agricultural purposes on account of the want of irrigation. The S. W. districts are the most fertile, producing grain and wine in abundance. Dense forests cover the S. slope of the Table and Zitzikamma mountains, but the country is not inviting. It contains the roughest mountain scenery, barren mountains, plains, valleys without trees or water, forming the very picture of dreariness and desolation, forming a remarkable contrast to the scenery of Natal and Caffraria. But the mountains are in some degree balanced by a salubrious climate to be found in the interior. For those whose health has been shattered by the climate of India a residence at the Cape is an almost unfailing cure. During the summer (Sept. to April), the temperature varies from  $70^{\circ}$  to  $90^{\circ}$  F., and the atmosphere is cooled by S. E. winds. The extreme temperature in the winter or rainy season is  $40^{\circ}$  and  $60^{\circ}$ . The mean of the year is  $65^{\circ}$ . The deficiency and irregularity of rains in the arid plains of the interior is one of the great impediments to agriculture. In some districts, during upon the Great Karroo, there has been no rain during 3 years, but when it descends in torrents that swell the rivers to extraordinary magnitude.—The colony is not very rich in mineral products. Iron abounds near Algoa bay and Seba. Copper ore has been worked with success for 8 years with considerable success, and coal have also been found;

of Ujtenhage; manganese in the district of Albany. Lime is prepared in large quantities from fossil shells, of which extensive quantities have been found in the district of Ujtenhage. The vegetation of the Cape colony is very rich in richness and variety. It is quite different from that of tropical Africa, and more similar to that of Australia, though the baobab tree, one of the prominent features of the Australian flora, is wanting at the Cape. In plants and heaths grow in beautiful profusion *proteaceae*, *restiaceae*, and *euphorbiaceae* is scarce. Of indigenous fruits there are few; but all kinds of fruit introduced from Europe are grown in abundance.—The colony comprises a great variety of wild animals, such as the elephant, rhinoceros, hippopotamus, lion, leopard, hyena, jackal, zebra, striped boar, antelope, monkey, raccoon, &c.; but most of these have become scarce in the thickly settled portions of the country. On the immense table-land back of the 3d main range the antelope, elk, springbok, and bant still roam in herds of incredible numbers. Yet even there hunting is very difficult. The Cape buffalo (*bos Caffer*), a powerful and untamable animal, has disappeared from the country and is only met with in the recesses of the mountains. Ostriches abound on the Karroo. Large herds of elephants are still to be seen in Natal. As both sexes of them have become of extraordinary size, they are eagerly hunted by the settlers. The hippopotamus is much hunted on account of his tusks, which are highly valued and higher in price than those of elephants. Of domestic animals only sheep and dogs are numerous. Horses, asses, mules, goats, and swine have been introduced from Europe. Benighted kinds of birds of prey, the country buzzards, pelicans, flamingoes, cranes, ibis, snipe, &c., are numerous, in numerous varieties. Fish are abundant on the coast and near the mouths of the rivers.—The entire population of the colony was, in 1856, stated to be 140,000. Of this number about 120,000 were persons of color, and 150,000 whites. The colored population consists of Hottentots or Khoes, Caffres or Fingoes (a nickname given to poor people, given to them by their adversaries, the Zulu Caffres), negroes, Malays, the descendants of Malay slaves introduced in former times by the Dutch. The Hottentots are a weak race, of small stature (under 5 feet), a yellow-brownish complexion, and coarse features, confirming by their appearance the opinions of the old Dutch colonists that they are only a connecting link between the monkey and the human. Those living in the colony have learned to discontinue many of the most filthy and disgusting habits of their savage ancestors, but are lazy, shiftless, and intemperate. Since, by the abolition of slavery, they have been put on an equal footing with the whites, their number has rapidly diminished. The Hottentot half-breeds are more industrious and intelligent. The negroes, mostly descend-

ants of former slaves or rescued from the slave-traders by the British cruisers, are perhaps still more vicious than the Hottentots. They abhor steady labor, and prefer to sustain a vagabond life by pilfering. The Malays are industrious, skilful, and thriving, but at the same time very passionate, vindictive, and violent. They profess the Mohammedan religion. A cross of the Dutch and Malays, generally named Africanders, are remarkable for the beautiful forms of their women. The Fingoes, about 25,000 in number, formerly inhabited the country S. W. of Port Natal, whence they were driven by the powerful Zulu tribe. They are rapidly advancing in civilization. Among the white inhabitants of the colony the Dutch element largely predominates. While the British for the greatest part live in the towns and cities as merchants, shopkeepers, military and civil officers, &c., the large majority of the farmers are descendants of the original Dutch colonists. These Boers, as they are called, have preserved the leading characteristics of their Dutch ancestors; they are a sturdy, cool-tempered, steady, and energetic race; thrifty, industrious, and of good moral character. The tenacity with which they cling to their customs, their local institutions, and their national character, long rendered them objects of the strong antipathy of the British, an antipathy heartily reciprocated by them. But within the last decade the mutual hatred and distrust have been greatly diminished. Those Boers who live at the outposts of civilization in the immediate vicinity of the savages, are, however, naturally in some degree savages themselves. The Boers are generally well educated, and there are scarcely any among them who cannot read and write the Dutch language. They are also pious and strict observers of all religious customs. Most of the men are tall and herculean in appearance; of the young women many are distinguished for a sort of majestic beauty; but at an advanced age both sexes incline to obesity. According to the 8 principal products of their industry they are known as Wine Boers, Corn Boers, and Cattle Boers. The Wine Boers are the wealthiest. Agriculture is still in a very primitive state, it being impossible to apply skilful and complicated implements on account of the difficulty of having them repaired or replaced. The Cattle Boers are the least educated and worst mannered of the whole class.—According to Herodotus, it is probable that the Cape of Good Hope was discovered by Phœnician navigators as early as 610 B. C. It was 2,096 years later when the Portuguese Bartholomew Diaz reached it. On Nov. 20, 1497, Vasco da Gama rounded the cape and pursued his course to India. But the Portuguese did not pay any attention to the Cape country. It was not before A. D. 1650 that the Dutch East India company established a colony there, in order to raise provisions for vessels going to India. In 1652 Cape Town was strongly fortified. The colony prospered admirably in spite of continued hostilities between

the settlers and the native tribes. An attack of the British during the American revolutionary war was repulsed, but in 1795 the colony was conquered by the British forces under Admiral Elphinstone and Gen. Clarke. Though restored to Holland in 1803, it was annexed once more to Great Britain in 1806, and finally ceded by Holland in 1814. The application of the British colonial system to the Cape country, the curtailment of the privileges formerly enjoyed by the settlers, the emancipation of the Hottentots in 1838, and the general tendency of the British rulers to put the savage native tribes on an equal footing with the settlers, disgusted the Dutch Boers, who after a protracted struggle of more than 20 years succeeded in establishing 2 independent republics beyond the boundaries of the colony. (See **BOERS**.) Beside these movements of the Boers, the history of the Cape colony under British rule consists mainly of wars with the Caffres. Five distinct wars were carried on against them, viz.: 1811-'12; 1819, by which the boundary of the colony was extended to the Keiskamma river; 1835, when the country lying between the Keiskamma and Kei rivers was annexed to the colony, but afterward restored; 1846-'48, in consequence of which the country between the Keiskamma and Kei rivers was constituted by Gov. Sir Harry Smith as a vassal state under the name of British Caffraria; and 1850-'53, when a formidable insurrection of the Caffres, resembling in many respects the Indian rebellion of 1857, was suppressed with great difficulty and after many reverses of the British arms. In order to tranquillize the Caffres and to keep them in permanent subjection, the British government established in 1856 and '57 a military colony in British Caffraria, consisting of several thousand members of the German legion, which had been organized during the oriental war by Gen. Stutterheim. Nevertheless, in the spring of 1858 one of the most powerful Caffre chieftains, Moshesh, chief of the Bosutis, who number about 20,000 warriors and had been subjected by the British in 1853, rose in arms against the Orange river republic, and it was anticipated that he would also invade the neighboring British province.—Ever since the emigration of the Boers great discontent had prevailed in the colony because of the want of a free representative government. When, in 1848, the British government proposed to send a number of convicts to the Cape, this discontent grew almost into open rebellion, compelling the government to desist from its purpose. It became evident also, during the Caffre war of 1850, that the colonists were unwilling to sustain a government which denied them rights that had been granted to the inhabitants of other colonies. Having at last become aware of this state of things, the British government in 1853 yielded to the demands of the colonists, and granted them a constitution which from an English point of view is very liberal. The colony is divided into 2 provinces, the western, comprising 8 di-

visions (counties), 10 divisions. The capital, Cape Town, are Wynberg, Constantia (Constantia wine derives it Town. The whole Cape peninsula, 6 to 8 m. broad) is included in the province.—The eastern province is a new country, having hardly been settled in 1820, when 5,000 Scottish there by the home government. The towns are Graham's Town and Port Elizabeth. Every division is governed by a commissioner, who is appointed by the governor, or justice of the peace. The civil and criminal jurisdiction is divided into districts, each with a resident magistrate of its own. The districts are again subdivided into feld cornets (meaning chief constables) are the principal legislative authority of the colony, elected by the governor, who is appointed by the queen's chambers called legislative council. Eight members from the western province, chosen for 5 years by the whole body of electors, sit upon a general ticket, constituting the assembly. No one can be elected who is not worth of £1,000 worth of landed property or £1,000 worth of landed and personal property. Any elector may give to one vote as there are 10 votes. The members of the assembly are elected for a term of 5 years by the election districts. The qualification of electors is the occupation of fixed property. The governor may dissolve the assembly. The queen has assented to by the governor, with its receipt.—The colonial government votes to the support of clergy of all Christian denominations. The numbers of the principal denominations in 1854: Dutch Reformed 60,000, Wesleyans 10,000, Anglicans 8,500, Independents 7,000, 1—Free schools are provided for all children. There are also 2 colleges in the colony.—The industry of the colony is not very extensive. Manufactories of soap, wagons, hats produce scarcely enough for local consumption. The internal commerce is not very developed in consequence of the want of communication, but the import and export trade has greatly increased since British rule, as may be seen from the

	Imports.
1836.....	£541,028
1840.....	732,424
1849.....	944,585
1850.....	1,377,161
1853.....	1,651,597
1854.....	965,286

The exports include also goods of value of the produce of the colony. In 1853 was £732,245. The p

ool, wine, hides and skins, aloes, ory, ostrich feathers, beeswax, &c. The exports of wool to Eng- 107 bales from Jan. 1 to July 1, 80 bales during the same period; total exports in 1853 were

The total value of exports from missions in Africa to the U. S. ar ending June 30, 1856, was during the same period ending 1, \$698,275. The imports from uted in the respective periods to to \$687,745. The revenue of risen from £130,808 in 1832, to 58, while the expenditures in the re only £126,889 and £268,111

**ORIN**, the most southern extrem- an, in the native state of Trav- 5' N., long. 77° 37' E., forming a andy point, which is not discern- distance of 12 to 16 m. from the e ship. Eighteen m. north from old summit called Comorin peak, rmination of the western Ghats, n a distance, been often taken for

Within a short distance of the sky islet, high above water; and n this islet are a fort and a village, n's houses, a church, and some a, being the remains of the once f Cape Comorin.

**MOND** is the extremity of an ab- ry of Lower Canada, at the junct- Charles and St. Lawrence rivers. tory stands the citadel of Quebec, and nearly on a level with the e plains of Abraham. Here was i, the memorable victory by the Wolfe, over the French, under

**IATO**, the S. extremity of Santa the Ionian islands. It is identi- ancient promontory of Leucadia, ed the Lover's Leap. The poet- aid to have thrown herself from promontory.

**LABETHI**, a headland projecting y, between Portland harbor in e Atlantic ocean. The coast is p of ledges of talcose slate, trav- of trap. There are 2 light-houses int, which stand 300 yards apart, feet above the sea.

**IOHEL** (probably the ancient omontorium) is on the W. coast 1 m. S. W. of Lisbon. It rises ab- e sea, and is crowned by a small light-house. It is of a whitish f. and reddish on the S. side.

**REWELL**, the S. extremity of t the eastern entrance to Davis's ong current sets around this cape, N. along the E. coast of the strait. :O (anc. *Pelorus*), the N. E. ex- ily. It is at the narrowest part

of the strait of Messina, opposite the rock of Scylla, on the coast of Calabria. The hill above the cape is fortified.

**CAPE FEAR**, the S. point of Smith's island, near the mouth of Cape Fear river, N. C. About 1 mile from the shore stands Bald Head light-house.

**CAPE FEAR RIVER** is formed by the union of Haw and Deep rivers at Haywood, Chatham co., N. C. It flows S. E. and enters the Atlantic by 2 channels, between which lies Smith's island. The water is from 10 to 14 feet deep over the bar at the main entrance. This is the largest and most important river which lies wholly within the state, and the only one in N. C. which flows directly into the sea. It is navigable by steamboats to Fayetteville, 120 m. from its mouth, and by means of dams and locks a communication has been opened with the coal mines of Chatham co. At Averysborough, the river falls over the ledge which separates the hilly from the low region of the state. After this, it flows through a flat, sandy district, partially covered with extensive forests of pitch pine. Its length, including one of the head branches, is about 300 m.

**CAPE FRIO** (Port. *Cabo Frio*, cool cape), a promontory on the coast of Brazil, with a light-house. It forms the terminus of a range of mountains running parallel to the coast, and consists of a huge oval mass of granite.

**CAPE FROWARD**, the southern extremity of S. America; lat. 53° 53' 42" S., long. 71° 18' 30" W. It is a bold promontory of dark slaty rock.

**CAPE GASPE**, a headland of Canada, and the N. boundary of the bay of Gaspé, in the gulf of St. Lawrence. The bay, which is 18 m. long and 8 m. wide, forms a secure harbor. The cod and whale fisheries are extensively carried on off its shores.

**CAPE GIRARDEAU**, a county of Missouri; pop. in 1856, 12,349, of whom 1,300 were slaves; area, 875 sq. m. It is separated from Illinois on the E. by the Mississippi river, and is drained by the head streams of the Whitewater, and by Apple creek. Abundance of good timber is found, and the cypress especially grows in nearly all parts of the country. The surface is level, and the fertile soil is carefully and extensively cultivated. The productions in 1850 were 510,730 bushels of Indian corn, 52,840 of wheat, and 65,677 of oats. There were 89 corn and flour, and 9 saw mills, 2 newspaper offices, and 10 churches. The first settlements were made by French and German emigrants, in 1794. Ospital, Jackson.—**CAPE GIRARDEAU**, a post village of the above county, has a good landing on the Mississippi river, and is the seat of St. Vincent's college.

**CAPE GRISNEZ** (anc. *Itium Promontorium*) is a headland of France (Pas-de-Calais), and the nearest point of the French coast to Great Britain. It has a revolving light 195 feet high.

**CAPE GWADEL**, or *Ras Noo*, a peninsula of Beloochistan, on the Indian ocean. It is

about 6 m. wide, and across its isthmus extends a ruined wall, near which stand the remains of a town, and a village of huts. On each side of the cape is a harbor; that on the W. side affords good anchorage.

**CAPE HATTERAS**, the easternmost point of N. C., a sandy insular spit, or narrow beach, separated from the mainland by the broad bay, called Pamlico sound. S. of the capes of the Delaware, no land stretches so far out into the Atlantic as Cape Hatteras. The gulf stream, in its E. and W. vibrations, often flows within 20 m. of the cape, crowding coasting vessels bound S., and consequently seeking to avoid the N. E. current, near to the shore. The difference of temperature between the hot airs of the gulf and the breezes along shore and from the land engender frequent commotions in the atmosphere at this place; and no point on the coast is more noted for its frequent and dangerous storms. A light-house is kept  $1\frac{1}{2}$  m. N. of the outermost point.

**CAPE HAYTIEN**, or **HAYTIEN**, formerly Cape Français and Cape Henry, a seaport town on the N. coast of the island of Hayti. Before the Haytien revolution broke out it was a handsome city, and some traces of its former elegance still remain. It has the safest harbor of Hayti, tolerably defended, and a fair trade with the United States, Great Britain, France, and Germany. In 1789 it had 18,500 inhabitants; before the earthquake of 1842 it had still 9,000, but in 1851 the population had diminished to about 6,000. In 1854, the entrances and clearances consisted of 190 foreign vessels, tonnage 30,970, and of 14 coasting vessels, 2,267.

**CAPE HENRY**, on the coast of Va., at the southern entrance of Chesapeake bay, has a fixed light 120 feet above the level of the sea.

**CAPE HORN**, also written **CAPE HOORN**, is a headland of an island of the Fuegian archipelago. It is a steep, black rock, with bare and lofty sides and pointed summits. It was formerly considered a very dangerous place to pass, but the difficulties of "doubling the cape" are now far less formidable. It was first discovered by the English navigator, Sir Francis Drake, in 1578, unless he was anticipated, as is claimed, by Garcia Jofre de Loaya, a Spanish commodore, in 1525, although it was first doubled by the Dutch navigators, Lemaire and Schouten, in 1646, the latter of whom gave it the name of his native city (Hoorn).

**CAPE ISLAND**, or **CAPE ISLAND CITY**, on Cape Island, Cape May co., N. J., is one of the most fashionable watering places in the U. S. During the summer months it has daily steamboat communication with Philadelphia, and the majority of the visitors who throng its hotels are from that city. Permanent pop. 600.

**CAPE LA HAGUE** (improperly written La Hogue), a headland of Normandy, France, is opposite the island of Alderney, and forms the N. W. extremity of the peninsula of Cotentin, in the English channel. It is often confounded with Cape La Hogue, on the opposite

e of (

**CAPE LANGUET**, a mountain of European Turkey, 2,290 feet in the termination of the Chi mountains, and the entrance of the Adriatic.

**CAPE LOOKOUT**, on the E. coast of N. C., has a light 100 feet above the sea.

**CAPE LOPATHA** is at the S. extremity of Kamtchatka. At the northern part of the headland is a mountain, bearing the same name, whence the land gradually slopes and narrows until it terminates in a low and barren tongue.

**CAPE LOPEZ**, the S. extremity of the bight of Biafra, on the W. coast of Africa. It forms a large bay, 14 m. long, into which empty several shallow rivers and creeks.

**CAPE MAY**, a county at the S. extremity of N. J.; area 250 sq. m.; pop. in 1855, 6,935. Its E. boundary is formed by the Atlantic; Delaware bay washes its W. shore, and Tuckahoe creek makes a part of its N. border. The surface is level and the soil entirely alluvial. The productions in 1850 were 84,915 bushels of Indian corn, 16,384 of wheat, and 11,027 of oats. There were 8 grist and 12 saw mills, 19 churches, and 1,860 pupils attending public schools. On the Atlantic coast is a beach, covered for the width of from  $1\frac{1}{2}$  to 2 m. with grass. Through the numerous inlets which divide this beach the sea penetrates into the marshes, about 4 m. in width, and forms lagoons or salt water lakes. In the N. part of the county is a similar marsh. Near Dennisville is a deposit of cedar timber in the soil to an indefinite depth. From the growth of vegetation above it, it is believed to be at least 2,000 years old, yet it is perfectly sound, and a number of persons are engaged in digging it up and converting it into posts, shingles, &c. This county was organized in 1719, and named in honor of Cornelius Jacobus May, a navigator in the service of the Dutch West India company, who visited Delaware bay in 1623. Capital, Cape May Court-house.—**Cape May**, a headland at the S. extremity of N. J., at the entrance into Delaware bay. It has a light which revolves once in 8 minutes, at an elevation of 90 feet above the sea. See **Cape Island**.

**CAPE MOUNT**, a river of W. Africa, emptying into the Atlantic. The district of Cape Mount, with its rivers, lakes, and islands, was deeded to an English company by the king of the territory, Feb. 28, 1841.

**CAPE NAU** (anc. *Lacinium Promontorium*), a headland of S. Italy, at the E. extremity of Calabria Ultra, was once the site of a temple dedicated to Juno Lacinia. Hannibal is said to have embarked here on leaving Italy, 203 B.C.

**CAPE NEDDOCK**, a promontory of Maine, 35 m. S. W. of Portland, with a light-house on Goat island near it, containing a fixed light 35 feet above the sea.

**CAPE NOONLAGMO**, or **NOONLAGMO**, at

extremity of Lawrence bay, on the Asia, not far from the point where it is nearest to the American continent.

**NORTH**, a celebrated headland at the N. E. extremity of the island of Magerøe, Northernmost point of Europe. It consists of a long chain of precipitous rocks that run into the sea. They are about 100 ft. high, and are crowned partly by a table-land and partly by pyramidal rocks. Lat.  $71^{\circ} 10' N.$ , long.  $25^{\circ} 46' E.$

**NORTH**, or Oroo, Orou, a peninsula at the N. E. extremity of New Zealand, about 2 m. long, terminating in a bluff head flat at the N. E.

**OF GOOD HOPE**, or **CAPE PEAK**, a promontory rising nearly 1,000 feet above the S. point of a narrow peninsula, near the S. W. extremity of the continent of Africa, having the Atlantic ocean on the S. and False bay on the E., 81 m. S. of Cape Town. Lat.  $34^{\circ} 22' S.$ , long.  $18^{\circ} 29' E.$

**PILLAR**, a high mass of rocks, terminating in 2 tower-shaped cliffs, at the S. W. extremity of the Pacific ocean into the straits of Magellan, and on the N. W. coast of Terra del Fuego.

**PRINCE OF WALES**, a promontory on the N. E. coast of the Arctic sea, the most N. W. point of the island of Greenland. It terminates in a peaked cliff, presenting a bold face to the sea, and is so named on account of a shoal which is named after the Prince of Wales.

**RIVER**, or **VAUNKA**, called also, from its source, Rio de Segovia, is a river in Central America, in the state of Nicaragua, flowing into the Mosquito territory. It flows through a fertile country, and after a course of about 100 m., enters the Caribbean sea at Cape Gracias a Dios. It is navigable for a considerable distance from the sea, but the upper part of the river is obstructed by cataracts and shallows.

**ROMAIN**, a low and barren point of land, with a light-house, 37 m. N. E. of Charlesfort.

**SABLE**, the southernmost point of the peninsula of Florida, and the site of Fort Mifflin.

**ST. AUGUSTINE**, the easternmost point of South America, on the coast of Brazil. It was discovered by Pinçon in 1500, and was the first European settlement in South America.

**ST. VINCENT** (anc. *Promontorium*), a headland at the S. W. extremity of the island of St. Vincent. Off this cape, Feb. 14, 1797, an naval force, consisting of 15 ships of the line, under Admiral Jervis, defeated a superior force of the French.

**SAN ANTONIO**. I. A high, barren, rocky headland, on the coast of Valparaiso. On its summit are a convent, a castle, and several windmills. II. A nearly perpendicular promontory, at the N. E. extremity of the Rio de la Plata, in the territory of Buenos Ayres.

**CAPE SAN BLAS**, a low point of land, about 2 m. long, on the S. coast of Florida. It has a revolving light 65 feet high.

**CAPE TAIMOOR**, **TAIMOUR**, **TAIMUR**, or **TAYMOUR**, a headland of Siberia, extending into the Arctic ocean. Next to Severo Vostotchnoi, it is the northernmost promontory of Asia.

**CAPE TINDARO**, a headland of Sicily, extending into the gulf of Patti. The remains of the ancient Tyndaris are in its neighborhood.

**CAPE TRAFALGAR** (anc. *Promontorium Junonis*), a headland on the coast of Cadiz, Spain. It is memorable for the naval battle fought near it, Oct. 21, 1805, between the English, under Nelson, and the combined fleets of France and Spain. The English gained a complete victory, though with the loss of their commander.

**CAPE TOWN**, the capital of the British territory in S. Africa, lat.  $33^{\circ} 55' S.$ , long.  $18^{\circ} 21' E.$ , situated at the bottom of Table bay, and at the foot of Table mountain, about 82 m. N. of the Cape of Good Hope. The town is well built and well laid out. There is a fortress near the town of considerable strength. Table bay is capacious, but the anchorage is rendered uncertain by the heavy swell of the Atlantic, which rolls its full volume against the coast. Cape Town is a station for astronomical observations, and Sir John Herschel passed 2 years at this port for the purpose of studying the heavens of the southern hemisphere. There is a castle and several batteries for the defence of the town and harbor. The chief public buildings are the government house, the colonial office, the barracks, the exchange, the post-office, the public library, 8 Anglican and 4 English dissenting churches, a Dutch Reformed church capable of holding 2,000 persons, and a handsome Roman Catholic church. The streets are laid out at right angles, and some of them are embellished with trees. Most of the houses are built of brick, faced with stucco; the interior is commodious, and some of them, in the older parts of the town, are decorated with architectural devices, and have in front raised platforms called stoeps. There is a capacious public walk, on one side of which are the gardens of the government house, and on the other the botanical garden. For imports and exports of Cape Town see **CAPE COLONY**. Pop. about 25,000.

**CAPE VERD**, the most westerly cape of the W. coast of Africa, between the rivers Senegal and Gambia; lat.  $14^{\circ} 48' N.$ , long.  $17^{\circ} 34' W.$  It was discovered in 1445 by the Portuguese navigator, Diniz Fernandez.

**CAPE VERD ISLANDS**, a Portuguese colony situated in the Atlantic ocean, 320 m. W. of Cape Verd, between lat.  $14^{\circ} 45'$  and  $17^{\circ} 13' N.$ , and long.  $22^{\circ} 45'$  and  $25^{\circ} 25' W.$ ; area, about 1,700 sq. m.; pop. in 1854, 86,488. The islands are of volcanic origin, and a volcano still exists on the island of Fogo. The shores are low, but in the interior there are high moun-

tains. The archipelago consists of 10 islands and 4 islets. The 10 islands are, Sal, Boavista, Mayo, Santiago, Fogo, Brava, Grande, Rombo, São Nicolao, and Santa Luzia; the 4 islets are, Branco, Razo, São Vicente, and Santo Antonio. The soil is dry but fertile. The heat of the sun is great, but the climate is tempered by the sea breezes. The rainy season lasts from the middle of August to November, and is unhealthy for Europeans. There is a great want of water and trees. Sometimes no rain falls for several seasons, and then the distress of the inhabitants is extreme. In 1832, after a 3 years' drought, 30,000 people perished. All the fruits of the S. of Europe and the W. of Africa flourish here, particularly oranges, lemons, melons, and bananas; so do rice, maize, wine, sugar, orchil, cotton, and French beans. Coffee was introduced in 1790. Indigo grows wild. Goats and fowls are very numerous; goat-skins are a principal article of export. Asses are reared and exported to the West Indies. The most remarkable of the wild animals are monkeys and bisam cats; venomous reptiles are unknown; whales are found in the neighboring seas, and turtles frequent the coasts. Salt, which is exported to North America, is manufactured on these islands. The total value of exports to the United States for the year ending June 30, 1856, was \$36,910; and of imports from the United States, \$53,709. In the same period, ending June 30, 1857, the value of the exports to the United States was \$25,905, and of the imports \$64,503, the latter amount comprising \$63,108 of the growth, produce, and manufacture of the United States, and \$1,395 of the growth, produce, and manufacture of foreign countries exported from the United States.—The natives are docile, indolent, and very religious. The Roman Catholic is the only form of worship. There are 12 schools upon the islands. Mulattoes, a cross between Portuguese and negroes, form the next most numerous race; the whites constitute about  $\frac{1}{5}$  part of the population, the slaves  $\frac{1}{4}$ . The language is corrupted Portuguese, which the Portuguese call *lingua creola*. As the sea between the continent and the islands is beset with haze and fogs during the greatest part of the year, ships sailing southward generally steer outside of the Cape Verd islands. The inhabitants have some commerce with Africa. The most considerable island of the group is Santiago, which is about 50 m. long and 23 broad in its widest part. It has a population of about 12,500 inhabitants. The governor resides at Porto Praya, a fortified seaport town on this island, with 1,200 inhabitants. The volcano of Fogo rises to the height of 9,157 feet. The islands were discovered in 1449 by the Portuguese, in whose uninterrupted possession they have ever since remained. On Jan. 1, 1857, there was a military force in the island of 3,028 men. The receipts of 1857-'58 are estimated at \$100,000, and the expenditures at \$140,000.

**CAPE VINCENT**, a son co., N. Y.; pop. 2 the St. Lawrence, at the and Watertown railroad, landing and a ship yard.

**CAPE WRATH**, a promontory at the S. W. extremity of Scotland. It consists of a pyramid of gneiss, 300 feet high, and surmounted by a light-house. The light is 400 feet above the sea.

**CAPECE-LATRO**, GIUSEPPE, an Italian prelate and statesman, born in Naples, Sept. 22, 1744, died Nov. 2, 1836. He belonged to one of the oldest Neapolitan families, and when very young was appointed to the archbishopric of Tarento, which gave him the rank and privileges of primate of the kingdom of Naples. His ecclesiastical advancement did not withdraw him from philosophical studies, and while devoted to his duties as a priest of the Roman Catholic church, he at the same time opposed many of the claims of the papal see. One of his early writings upon the tribute paid by the kingdom of Naples to the court of Rome excited considerable attention. He caused a greater commotion by his work against the celibacy of priests, an institution which he maintained to have been the principal occasion of the Protestant reformation, and to be still the main source of the antipathy to the Catholic church, felt by a great number of its opponents. When the revolutionary spirit began to manifest itself in Italy, Capece-Latro directed the attention of Queen Caroline to the abuses in the government, but he was not listened to. When the revolution at length broke out, in accordance with the wishes of the people he accepted a public office. Upon the restoration of the Bourbons, Capece-Latro was thrown into prison, and marked out as one of the first victims of sacrifice. But all parties deciding and uniting to save him, the government was forced to release him, and offered him his liberty as an act of royal clemency. The prisoner would not take freedom on such terms. Refusing favor, he demanded justice, and the king found himself obliged to make excuses to him. During the government of Joseph Napoleon at Naples in 1806, Capece-Latro was minister of the interior, and continued in the position with distinguished success under Joachim Murat. After the fall of this king, the prelate lost his archbishopric; he withdrew from public affairs, and made his house a place of reunion for persons of distinguished rank or wit. His last work was in praise of Frederick II. of Prussia.

**CAPEFIGUE**, BAPTISTE HONORÉ RAYMOND, a French historian, born in Marseilles in 1801. He was the school-mate of Thiers and Mignet; in 1821, the 3 repaired to Paris to study law, but soon became engaged in historical studies and politics. Capefigue joined the royalists, and became one of the writers of the *Quotidien* newspaper. In 1823 he attracted some attention by his *Récit des opérations de l'armée Française en Espagne*. The same year he published

his first historical book: *Essai sur les invasions des Normands dans les Gaules*. From that time he pursued, with unfailing activity, his twofold task of historian and journalist. In 1827 he gained considerable reputation by his *Histoire de Philippe Auguste*, which is still considered his most valuable performance. He has since been an important contributor to several newspapers, most of them in the royalist interest. He has also published numerous historical works. He has thus treated the entire annals of France from the 10th century to our time, the whole forming a little less than 100 volumes, one-third of them devoted to the last 75 years. Although they contain valuable information and curious documents, they cannot be compared with the histories of Thiers, Mignet, Michelet, Augustin Thierry, and Guizot.

CAPEL, ARTHUR, lord, an English royalist, elected to the long parliament in 1640, died March 9, 1649. He voted for the death of Strafford, and then returning to the cause of Charles I., raised and maintained a troop in his interest, and fought against the parliamentarians at Bristol, Exeter, Taunton, and Colchester. Captured in the last city, he was condemned for treason, and met his death with firmness. He wrote "Daily Observations or Meditations, Divine, Moral, and Political."—His son, also named ARTHUR, born in 1635, created earl of Essex by Charles II. in 1661, was lord lieutenant of Ireland, 1672-'7. Afterward involving himself among the enemies of the court, he was arraigned for participation in the Rye-House plot, and was found with his throat cut in the tower, July 13, 1683.

CAPELL, EDWARD, a Shakespearian commentator and critic, born at Troston, in Suffolk, England, in 1713, died in London, Feb. 24, 1781. Under the patronage of the duke of Grafton, he became deputy inspector of plays, an office which left him leisure for his Shakespearian studies. He published his edition of the works of Shakespeare, 10 vols. 8vo, 1767, "Notes and Various Readings of Shakespeare," 4to, 1775, and the "School of Shakespeare," 3 vols. 4to, 1783, was issued 2 years after the author's decease. His labors continued for more than 40 years.

CAPELLA, MARCIANUS MINEUS FELIX, a writer who flourished in the 5th century, but of whose life little is known. He was probably a native of Carthage. His principal work is a curious allegorical medley in prose and verse, composed in imitation of Varro's *Satyra Menippea* and Petronius' *Satyricon*, and entitled *Satyra de Nuptiis Philologiae et Mercurii*. It consists of 9 books, of which the first 2 describe the marriage of Philology and Mercury, and the remaining 7 treat of the liberal sciences. Copernicus is supposed to have derived a hint of his system from an assertion in one of these books that Mercury and Venus revolve about the sun, and Boethius is said to have taken from Capella the model of his *Consolationes Philosophicae*. The best editions of Capella are

those of Hugo Grotius, 8vo, Leyden, 1599, and Kopp, 4to, Frankfort, 1836.

CAPELLO, BIANCA, grand duchess of Tuscany, born in Venice, 1542, died at Poggio, Oct. 19, 1587. In 1563 she eloped with a banker's clerk, of the name of Pietro Buonaventuri, who, barely escaping from the vengeance of her father, put himself under the protection of Francesco de' Medici at Florence. Bianca's beauty and accomplishments fascinated Francesco, and although but recently married to Joanna, arch-duchess of Austria, he caused the fair Venetian to reside in his palace, attaching her husband to his household as steward. In 1570, when the arrogance of Buonaventuri became unbearable, he was put to death by order of Francesco, who, on the decease of his father Cosmo I., ascended the throne of Tuscany. Bianca presented him with a son Aug. 29, 1576, which however was not her own, but was procured from a poor woman, and in order to preclude the detection of the imposture, she caused the assassination of most of those who had assisted her in its perpetration. In 1577 Joanna of Austria bore a son to the grand duke, and as she soon afterward died, while she was pregnant with still another child, Francesco was, for a moment, overcome with contrition and remorse, and seemed disposed to discard Bianca; but the cunning woman knew how to beguile her lover, and in two months he married her. The marriage was approved of by Philip II. of Spain, and solemnly ratified by the republic of Venice, the official marriage ceremony taking place in Oct. 1579. In 1582 Francesco's son by Joanna of Austria died, and as there was no prospect of seeing her supposed son adopted as heir to the throne, Bianca endeavored to reconcile herself with Francesco's brother, the cardinal Fernando de' Medici, who, in all probability, would succeed him as grand duke. In Oct. 1587, the 2 brothers and Bianca met at Poggio, and a few days afterward the grand duke and Bianca were taken suddenly ill with the same disease, of which they both died. Bianca had ever been an object of hatred to her brother-in-law, and it was believed that Fernando had poisoned her with her husband; but there is no judicial or historical evidence to support the supposition.

CAPER, the flower bud of a low shrub (*caparis spinosa*), which grows on walls and ruins, or on rocks and accumulations of rubbish, in the south of Europe and the Levant. It is very common in Italy and in the southern parts of France. It grows wild upon the walls of Rome, Florence, and Sienna, and is cultivated on a large scale between Marseilles and Toulon, and also in many parts of Italy. It begins to flower in the early part of summer, and flowers continuously until the commencement of winter. The buds are picked every morning before the petals are expanded, and are put into vinegar as they are gathered. They are distributed according to their size into different vessels and prepared for the market; the youngest and the smallest, being

most tender, are the first in quality; and hence the different sizes are placed in separate vinegar jars, denoting difference of quality and value. The stems of the caper bush are trailing and 2 or 3 feet long. The leaves are alternate, ovate, veined, and of a bright green color. The flowers are white, large, and beautiful, with a tinge of red. They are divided into 4 petals, and from the centre of each flower springs a long tassel of deep lilac stamens. The brilliant blossoms give a very gay appearance to the plant.

**CAPERNAUM**, a city of Palestine, often mentioned in the New Testament, and memorable as the scene of many of the works of Jesus. The neglect of the inhabitants to profit by the instructions that were given them led to the well-known declaration of Matt. xi. 23. This ancient city seems to have been on the W. coast of the sea of Genesareth; but travellers have not been unanimous in pointing out its locality. A long series of traditions identified it with a ruined village, known at present as Khan Minyeh, until the 17th century; since then it has generally been fixed at Tell Hûm, a spot further N. on the seacoast. Dr. Robinson inclines to restore the ancient tradition, for reasons which he gives at length in his "Biblical Researches in Palestine and the Adjacent Regions," vol. iii., pp. 348-358.

**CAPERS, WILLIAM, D.D.**, an American clergyman, late one of the bishops of the Methodist Episcopal church south, born in St. Thomas' parish, S. C., Jan. 26, 1790, died at Anderson, S. C., Jan. 29, 1855. He received the degree of A.M. from South Carolina college, and subsequently the honorary degree of D.D. In 1809 he was received into the S. C. conference, filling some of the most important stations in its bounds. In 1821 he was appointed missionary to the Indians in western Georgia, and travelled extensively throughout the state pleading the cause of missions. The year following he established a mission among the Creek Indians on Flint river. In 1825 he was stationed in Charleston, where he remained as preacher in charge and presiding elder for 6 years. For a part of this time he edited the "Wesleyan Journal," which was subsequently merged in the "Zion's Herald," and now bears the name of the "Christian Advocate and Journal" in New York. In 1835 he was elected professor of the evidences of Christianity in the university of S. C., a post which he afterward resigned to take charge of the "Southern Christian Advocate." After remaining in the editorship of this paper 5 years, the general conference appointed him to the office of general missionary secretary for the south, the north being assigned to Dr. Bangs, and the west to Dr. now Bishop Ames. This appointment he held until the ensuing general conference, during which time he travelled extensively over the south, presenting the claims of missions upon the attention of the church. At the first general conference of the M. E. church south he was elected and consecrated bishop (1846), which office he filled with

**CAPET**, the nickname of Hugues, or Hugh, the 1st king of the 8d French dynasty. Considerable difference exists among the learned concerning the etymology of this appellation. Pasquier derives it from a half Latin word meaning head or chief; Du Cange, from *chapin*, a provincial word of Auvergne, meaning a jester, as Hugh, during his early youth, was wont, by way of jesting, to throw down the caps of his companions; others from *capit*, a large head; others from *chapeatus*, a man wearing a cope, a sacerdotal cloak. Indeed, the first Capetians were abbots of St. Martin at Tours and King Robert, the son of Hugh, used to sing at vespers arrayed in the sacerdotal cloak; the old banner of the same king was simply a St. Martin's cloak.

**CAPETIANS**, the 8d race of French kings, beginning with Hugh Capet. Their origin is usually traced back to Robert the Strong, a warrior of Saxon descent, who held in fee from Charles the Bald the county of Anjou and afterward the duchy of France. He gained great popularity by his struggles against the Norman pirates who invaded France during the 9th century. Three of his descendants, Eudes, Robert, and Raoul, assumed the title of king in competition with the Carolingian princes; but the crown was not firmly established in this family until the election of Hugh Capet. This appears to have been a kind of national protest on the part of the Gallo-French population against the descendants of Charlemagne, who then depended on German princes. The Capetians, several of whom were distinguished as able politicians or great warriors, strengthened their position by close alliance with the clergy, and the assistance they received from the *communes* or municipal cities. They were 14 in number, and reigned from 987 to 1328, as follows: Hugh Capet, Robert the Pious, Henry I., Philip I., Louis VI. the Fat, Louis VII., Philip Augustus, Louis VIII., Louis IX. or St. Louis, Philip III. the Bold, Philip IV. the Fair, Louis X., Philip V., and Charles IV. From this main stock issued several collateral branches, the most important of which are the following: Robert, the grandson of Hugh Capet and brother of Henry I., in 1033 founded the first ducal house of Burgundy, which became extinct in 1361; Pierre, the 8th son of Louis VI., married Isabelle de Courtenay, and had 8 descendants who reigned at Constantinople during the 13th century; Charles, count of Anjou, the 8th brother of St. Louis, was the head of the first house of Anjou, which held

of Naples from 1264 to 1282. Robert, count of Flanders, was the head of the house of Bourbourg, which succeeded to the French throne in 1295, while his grandson, Charles, the brother of Philip the Fair, founded the house of Valois, and came into possession of the crown on the extinction of the direct Capetian line.

**CAPIAS** (Lat. *capiō*, to take) is the name of a species of judicial writs in actions at law, which command the sheriff or other officer to take a party or property named. *Capias ad respondendum*, which orders the sheriff "to take the body of the defendant and keep the same to answer" (*ad respondendum*), is the writ ordinarily referred to by the name *capias* when used alone.

**CAPILLARY ACTION** (Lat. *capillus*, a hair), manifestation of the force of adhesion shown in the movement of a fluid upon a solid surface coated partly within the fluid. It is called capillary because it is most striking on the inside of very small tubes—capillary (hair-like) tubes. If a solid can be wet by the fluid, the fluid will rise in the tube, or on any surface, as water on glass or wood. If the solid cannot be wet by the fluid, the fluid will be depressed in the tube, as mercury is depressed in a glass tube. Capillary action has been investigated with great accuracy both by experiment and calculation, but the most is chiefly theoretical, its practical laws being obvious. See Laplace's *Mécanique céleste*, vol. iii.

**CAPILLARY VESSELS**, minute vessels intermediate between the arteries and veins, the smallest branches of the former and the smallest of the latter; they are found in almost every tissue of the animal body, communicating freely with each other, and forming extensive networks or plexuses, whose intercommunications are in proportion to the importance of the activity of the organs. Their walls are composed of a delicate membrane, without elastic fibres, often presenting on its external surface oblong nucleated cells. The diameter of the vessels of different animals according to the size of the blood globules; in man it is from the  $\frac{1}{1000}$  to the  $\frac{1}{500}$  of an inch. The dimensions are not constant, but vary according to disturbances in the general or local circulation. The existence of capillaries too small to admit a blood globule, and adapted only for the reception of the serous portion of the blood, is not doubted by the best physiologists of the present time, and therefore the idea that nutrition may be carried on by means of capillaries may be abandoned; some tissues, as cartilage, have no vessels, and yet they are nourished by the blood, whose nutrient materials are absorbed by the tissues nearest the vessels and then passed on to the cells of the non-vascular structures. Such is the relation between the plan and minuteness of the capillary work and the character and function of the tissue supplied, that it is possible to judge with considerable accuracy of the part from which a

specimen has been taken. The network is the closest where some change is to be effected in the blood itself, as in the lungs and glands, and the most open where the blood is received merely for purposes of nutrition of the tissue; in the nervous centres and the muscles the network is fine, on account of the required activity of their molecular changes. In warm-blooded animals the rate of the capillary circulation is about  $\frac{1}{100}$  of an inch in a second, or  $1\frac{1}{2}$  inch in a minute. Comparing this with the rate of movement in the larger arteries (about 11 $\frac{1}{2}$  inches in a second), Volkmann has calculated that the aggregate area of the capillaries must be nearly 400 times that of the arteries which supply them. The movement of the blood through the capillaries is principally dependent on the force of the heart and the contraction of the arteries; but the circulation of the lower classes of animals, and of plants, proves that there is some power independent of that of a central organ sufficient to move the blood in these vessels—a power originating in the vessels and intimately connected with the activity of the processes of nutrition and secretion. The capillary circulation may continue after the cessation of the action of the heart, may cease in certain parts while the heart is actively contracting, and is constantly retarded and accelerated by causes of entirely local character. If the web of a frog's foot be examined under the microscope, the current is seen at one time slow, at another rapid, sometimes in one direction, sometimes in the opposite, and occasionally perfectly still, according to the strength or weakness of the neighboring currents, from entirely local causes; if the heart's action be impeded, these irregularities will be more marked. The emptiness of the arteries after most kinds of death, partly due to the tonic contraction of these vessels, is rendered complete by the longer continuance of the capillary circulation. It is well known that the kidneys, the skin, and its glands, continue their secretions for a time after death, which would be inexplicable without the activity of the capillary circulation in these parts. In the early embryonic stages of the higher animals a circulation is seen before the formation of a central heart, and the first movement is toward, and not from, the centre. In the case of the foetus without a heart, though in connection with a perfect twin, the circulation is kept up by the capillary power, which, though generally subordinate to the heart, is sufficient for the maintenance of the circulation without the aid of the central organ. In many cases of fatty degeneration of the heart there is scarcely a trace of muscular tissue, and yet the circulation may be carried on for a long time without any serious disturbance; in such cases a capillary power must be active. Wherever there is any local excitement in which the processes of nutrition and secretion are interested, there will be an increase in the local amount of blood and a more rapid circulation in the capillaries. The

cessation of the capillary power, and the consequent obstruction of the circulation, even though the heart's action be unimpaired, may cause gangrene of the solid tissues; the prolonged influence of severe cold destroys the life of a part by its action on the capillaries; if the admission of air into the lungs be prevented, the pulmonary capillary circulation is arrested as soon as the blood becomes loaded with carbonic acid, and asphyxia is the result, unless a fresh supply of oxygen be speedily obtained. Without admitting any contractile power in the capillaries, or any mechanical aid to the circulation, the motion of the blood through them is certainly affected by any change in the chemico-vital relations between this fluid and the tissues; the heart sends the blood to the capillaries, but its passage through them is rapid or slow according to the activity or depression of the processes to which it should be subservient. Prof. Draper, of New York, has established the following principle, which seems to explain the movement of the blood in the capillaries: "If 2 liquids communicate with one another in a capillary tube, or in a porous or parenchymatous structure, and have for that tube or structure different chemical affinities, movement will ensue; that liquid which has the most energetic affinity will move with the greatest velocity, and may even drive the other liquid before it." The arterial blood, rich in oxygen, with which it is eager to part, has a greater affinity for the tissues than has venous blood, loaded with carbon; therefore, on the above principle, the arterial blood of the systemic capillaries must drive before it the venous blood, and this in proportion to the perfect oxygenation of this fluid. In the lungs, on the contrary, the venous blood, rich in carbon, has the strongest affinity for the oxygen of the inspired air, and must drive before it in the pulmonary capillaries the arterial blood, already saturated with oxygen, and therefore having no affinity for the chemical elements of the air; and this in proportion to the perfection of the act of respiration. The chemico-vital actions of the systemic capillaries, though no more important to life, are much more complex than those of the capillaries of the lungs. In the latter it is a mere interchange between carbon and oxygen, while in the former every organ and tissue attracts to itself the materials necessary for its own nutrition, and causes a circulation in it in accordance with the above-mentioned physical principle. Though the capillary circulation is in a great measure independent of the direct agency of the nervous system, it is modified by the control exercised by the sympathetic nerves over the smaller arterics, and by the influence of the nervous system on the molecular changes in which the processes of nutrition and secretion consist. Though the blood will circulate after the division of the nerves of a part, any sudden and violent shock to the nervous centres will instantly arrest the capillary circulation. To use a homely illustration: if we com-

the a

source, and the system of sewers, which purities and excess of regard the capillaries as the enter every house, on which and regular performance of the of every-day life, without which no comfort, cleanliness, health, or

CAPIS, a province of the Spanish pines, forming the N. portion of the of Panay; area, 1,680 sq. m.; pop. 219,122. The soil is exceedingly fertile, and irrigated by a great number of small mountain streams. The product of rice is remarkably abundant, yielding in many places as much as 200-fal, while the land can be cropped twice a year. The inhabitants are of the Bisaya race, and noted for their docility of character, industry, and fidelity to the government. The town of Capis is a place of considerable native trade; pop. 11,520.

CAPITAL (Lat. *caput*, head), in architecture the head of a column or pilaster; in political economy, accumulated and productive wealth, whether in the form of money, buildings, machinery, improvements on land, or merchandise; in geography, the chief town of a state or district.

CAPITAL PUNISHMENT (from *caput*, head, the source of life; hence *capitalis*, anything affecting life, as *crimen capitalis*, capital crime; *pana capitalis*, capital punishment, in modern law, the punishment of death. A capital offence by the Roman law imported only a loss of civil rights (*amissio civitatis*). In the primitive state of social organization, at least in the earliest condition of which we have any record, retaliation was the common method of punishing offences, and this was inflicted by the individual suffering the injury, or by his friends when the injury was loss of life. The right of individual revenge has not only existed in the savage state, but has been recognized, and to some extent tolerated, even after laws have been enacted for the restraint of crime; and in the laws of many nations, retaliation, that is, the infliction of the same injury upon the offender which he had committed, was allowed.—Moses prescribed, as the measure of punishment for corporal injuries, an eye for an eye, a tooth for a tooth, and life for life, Exod. xxi.; Levit. xxiv.; and it would seem, in the latter case, that any person belonging to the family of the person whose life had been taken could pursue the murderer and slay him. "The avenger of blood" was a person having such right of private vengeance, and not a public officer appointed for that purpose. The only means of escape from this mode of retribution was by fleeing to certain cities of refuge, and this was available only in cases of what we should call excusable homicide.—The offences designated by the law

different nations as punishable by death, are indicative of the degree and peculiar form of civilization.—The Hebrew polity being theocracy, many offences were punished capitally as violations of the national faith. Thus violation of the sabbath, blasphemy, idolatry, witchcraft, cursing, offering children to Moloch, disobedience to parents, were punished by death. Murder, adultery, incest, kidnapping a person and selling him for a slave, and other offences, were also capital.—The code of laws established by Draco prescribed the punishment of death for a large number of offences, greatly differing in degrees of criminality, which the lawgiver extenuated by providing that the smallest of the crimes specified deserved death, and there was no greater punishment which he could inflict for more heinous crimes. This severity was afterward very much modified, and the Athenian criminal code became very mild, subject, however, to an arbitrary power reserved to the assembly of the people over the lives of all the citizens, and also to the discretion, which in many instances was left to the areopagus, and even to the dicasts of the people, of determining the punishment as well as the guilt of the accused; as in the case of Alcibiades, who, after trial by the court of areopagus, and being convicted of the charge against him, was retried with reference to the punishment. It was generally in the power of the Athenian to escape from a trial, if he was willing to incur the risk, by going into voluntary exile. Arrest before trial was not a practice in judicial proceedings, either civil or criminal, in the Athenian courts. The crimes ordinarily punished by death, or for which death was prescribed by law, were impiety (any open disrespect for religious rites or popular faith), treason, murder, and attempt to murder, and incendiarism. There have been some other cases, but we have no distinct record of them. The charge against Alcibiades, which drove him into exile, was the mutilation of the busts of Hermes which had been placed in the streets of Athens. Alcibiades was accused of disbelief of the national religion. Although the judgment of the areopagus in the case of Socrates was unjust, yet the ordinary administration of justice by that court was impartial and lenient.—The Roman laws compiled by the decemvirs were severe. *Lex talionis*, or punishment like to the injury, was admitted in cases of maiming or other corporal violence; but exemption could be obtained by a pecuniary compensation. Montesquieu mentions the singular provision by which the penalty of death was denounced against the authors of libels and poets, as showing that they were framed for the support of a despotic government. The severity of the 12 tables, which the laws had been digested by the decemvirs, was prevented from having full effect by the Valerian laws (which had been previously passed in the consulship of Valerius Poplicola), taking from the consuls the

power of inflicting the punishment of death, and giving an appeal from the consul to the people in all cases, and finally by the Porcian law, A. U. 454, forbidding any one to bind, scourge, or kill a Roman citizen. Criminal jurisdiction in capital cases was, therefore, vested in the assembly of the people. Trials were always had in those cases before the *comitia centuriata*. The same usage prevailed at Rome which existed at Athens, viz.: of allowing a criminal accused of a capital crime to go into voluntary exile, and thus avoid the judgment of the court; but, in such cases, his property could be confiscated for non-appearance.—The Germans, in their primitive state, allowed private retaliation for injuries, and long after they had become established as nations within the territory of the Roman empire, and had become subject to codes of laws, this was still considered a natural right, and judicial authority interposed no check except to impose terms of compromise, when the injured party was willing to accept pecuniary compensation. The Salic law prescribed the rate of composition for different crimes, which was called *wehrgeld*, prohibition money (from *wehren* or *bewahren*). It was, however, assumed that the injured party had a right to choose whether to take the composition, or to get satisfaction by his own hand. Similar provisions are found in the laws of the Burgundians, Visigoths, and Ripuarian Franks. The Anglo-Saxons, like the other German nations, had a scale of fines for every species of crime; that for murder was called *moigbota* or *manbota*. Retaliation was the common mode of redress, and private feuds prevailed to a great extent, which for a long period could not be controlled by law. Magistrates, however, were authorized to compel the injured party to accept the fine. If the wrong-doer (in case of murder) kept himself in his own house, it was permitted of his adversary to besiege him, and if he should surrender himself, he might be detained 80 days, but was then to be delivered up upon paying the prescribed compensation. This was enacted by the laws of Alfred. By the Mercian laws, the price of a ceorl's head was 200 shillings, that of a thane 1,200. Beside paying the relations of the deceased, a murderer was also obliged to make compensation to the master if the deceased was a slave, or to the lord if the deceased was a vassal under his protection. It was common for the poorer class to enrol themselves as the retainers of some superior, who was then bound to protect them. Associations were also formed among men of the same class for their mutual protection—the obligation assumed being to pursue the murderer of any one belonging to the association, and inflict punishment.—By the common law of England, no punishment can be adjudged, except what is prescribed by law. The penalty for all crimes must be fixed by statute, or otherwise courts can adjudge none. There was during a long period a serious interference with the regular administration of criminal justice, growing out

, from the quinquennial celebration  
at *Capitolini*.

—In German constitutional  
history, the contract which the German electoral  
college entered into with the German emperor,  
which was raised to the imperial dignity.  
The first of these capitulations was exacted  
from Charles V. at the commencement of the  
16th century, by the German princes who  
declared that the king of Spain would not respect  
the liberties put upon him by the constitution  
of the German empire. They accordingly drew  
up a capitulation, reciting the privileges they  
claimed to the observance of which Charles  
was obliged to swear. The last of these  
capitulations was sworn to by the em-  
peror Charles II., July 5, 1792.

ULARIES, certain laws enacted under  
the Frankish kings, and so named from the cir-  
cumstance of their being divided into *capitula*,  
or chapters. They were issued by Childebert,  
Charlemagne, and Pepin, but still more  
famous by Charlemagne, whose object ap-  
parently has been to harmonize, explain, or  
reform the existing feudal codes, and effect to  
bring about a uniformity of law in his domin-  
ions. These enactments were both civil and  
criminal; according to Savigny, the latter  
prevailed throughout the 8 kingdoms sub-  
jected to the rule of Charlemagne, but the former  
only within the state in which they  
were issued. The capitularies were promulgated  
in public assemblies, composed in Charle-  
magne's time of the sovereign and chief clerical  
and lay magnates, though in earlier times all  
able of bearing arms seem to have  
partaken in them. The laws were inscribed  
on parchment, and deposited in the  
royal archives in the Latin tongue,  
and translated to the people in the vernacular.  
The execution was intrusted to the bishops,  
counts, and the officers called *missi regii*,  
sent under the French kings of the  
second race to administer justice in  
the provinces. The earliest enactment coming  
under the name of capitulary was made by Chil-  
debert, A. D. 554, and the latest by Charles the  
Fat, who died in 929. The first collection  
of capitularies was begun in 827 by An-  
selm of Fontenelle, and continued  
by the deacon, of Mentz. It was ap-  
proved by various kings and councils, and had  
the force of law. Additions have since been  
made to his collection, and the first complete

edition was published by Vitus Amerpachius at  
Ingolstadt in 1545, under the title of *Præci-  
pue Constitutiones Caroli Magni de Rebus ec-  
clesiasticis et civilibus*. The best edition is that  
of Baluze, entitled: *Capitularia Regum Fran-  
corum*, &c., Paris, 1677, 2 tom. fol.; reprinted  
at Venice in 1771, and at Paris in 1780.

CAPMANY Y MONTPALAU, ANTONIO DE,  
a Spanish writer, born in Barcelona, Nov. 24,  
1742, died in Cadiz, Nov. 14, 1818. He served  
in the wars with Portugal in 1762, left the  
army in 1770, and joined Olavide in his scheme  
for colonizing and cultivating the Sierra Morena.  
This enterprise terminated disastrously, and  
Capmany removed to Madrid, where he was  
chosen secretary of the royal historical academy  
of Spain in 1790, and filled several offices in the  
gift of the government. He travelled in Italy,  
Germany, France, and England. When the  
French entered Madrid in 1808, he fled to Seville,  
where he arrived destitute and in rags. He  
was chosen a member of the cortes of Cadiz, in  
which capacity he made himself conspicuous  
by his patriotism and active opposition to the  
new rulers. His works, which enjoy a high  
reputation in Spain, are numerous; among  
them are *Memorias historicas sobre la Marina*,  
*Comercio y Artes de la antigua Ciudad de*  
*Barcelona*, in 8 vols. 4to; *Questiones criticas*  
*sobre varios puntos de historia, economica, poli-  
tica y militar*; *Teatro historico-critico de la*  
*Elocuencia Española*; and *Diccionario Fran-  
ces-Español*.

CAPO D'ISTRIA, a city, pop. 6,500, and  
county, area 168 sq. m., pop. 43,600, in the  
margraviate of Istria, one of the crownlands or  
provinces of the Austrian empire. The city is  
situated upon a rocky island, 9 m. S. of Trieste,  
connected with the mainland by a solid stone  
bridge 2,800 feet long. It has crumbled walls  
and fortifications, a large number of old di-  
lapidated buildings and narrow and crooked  
streets. The city is said to have been founded  
by the Colchians, under the name of *Ægida*;  
in the 6th century A. D., many wealthy fami-  
lies sought a refuge there from the Longobards  
and Avari. Having been conquered by the em-  
peror Justinian I., it was named by him Justin-  
opolis, in honor of his uncle, Justin I. Later it  
became an independent commonwealth; was  
annexed to Venice in 982; conquered by the  
Genoese in 1380; was independent again in  
1478, until the whole margraviate became part  
of the Austrian dominions. The city has a good  
harbor, a cathedral and 80 churches, beside 2  
convents, a college, and an academy, extensive  
salt works, an aqueduct, &c.

CAPO D'ISTRIA, or CAPODISTRIAS, a noble  
family which has flourished on the Ionian islands  
from the 14th century, and which is intimate-  
ly connected with the early history of the  
modern Greek kingdom. I. JOHN ANTHONY,  
count of Capo d'Istria, president of Greece from  
1827 to 1831, born in Corfu in 1776, assassi-  
nated at Nauplia, Oct. 9, 1831. He received a  
classical education at Padua and Venice, in-

tending to become a physician, but the political disturbances which his country experienced under Napoleon led him to a political career. When, after the expulsion of the French by the united Russian and Turkish forces, the Ionian islands became a vassal state of Turkey, under British and Russian protection, Capo d'Istria filled several public stations, and from 1802 to 1807 united the secretaryships of the interior, foreign affairs, the navy and commerce, in his own hands. The islands having been returned to France by the treaty of Tilsit, Capo d'Istria accepted a place in the Russian ministry of foreign affairs, where he soon gained distinction. As a member of the Russian embassy at Vienna in 1811; as a diplomatic commissioner at the headquarters of the army of the Danube in 1812; as a diplomatic agent of Russia in Switzerland in 1813, where he was prominently instrumental in imposing upon the people the federal constitution, which endured till 1848; lastly, as a member of the congress of Vienna in 1815, and the principal author of the resolutions of Carlsbad in 1819, Capo d'Istria was always found among the firm supporters of absolutism, though at the same time denouncing the despotism of Turkey, and secretly conspiring for the independence, or rather Russification of Greece. In 1816 he was appointed secretary of foreign affairs in Russia. In 1819 he visited his native country in order to sound the popular feeling. The results of his visit were stated by him in a small pamphlet, in which he endeavored to demonstrate that it was the province of absolute governments to educate the people for the enjoyment of freedom. This doctrine was not at all palatable to the leaders of the Greek insurrection, and the movement begun by them in 1821 was therefore disavowed by Russia so long as it seemed impossible to turn it to account for the secret objects of Russian policy. He lost his office in 1822, and went to Switzerland, where he succeeded in regaining the confidence of the Greek leaders. With the consent of the British ministry and the Russian government, both desirous to place a devotee of monarchical order at the head of Greece, he was elected president or regent of Greece by the national convention assembled at Damala (1827). Before assuming the government he went to St. Petersburg, where, it is generally believed, he received secret instructions from the Russian government. He landed at Nauplia, Jan. 28, 1828. For a very short time he commanded the confidence of the people. Instead of fulfilling his pledge to form a great national army and repulse by force the Turkish army under Ibrahim Pasha, he left the defence of the country to foreign diplomacy, crushed the liberty of the press, drove the patriots and heroes of the revolution from public offices, which were filled by him with his own creatures, promulgated a code of laws of the utmost severity, prevented the election of Prince Leopold of Saxe Coburg to the throne of Greece, and seemed to have no other object in view except to prepare Greece

for Russian

became the most violent of his measures as a result of the French revolutionary movements which assistance enabled him to suppress. he was stabbed by the brothers Constantine and George Mauromichalis, as he was entering the church of St. Spiridion. II. / brother of the preceding, born in 1770 at Corfu, in 1857. He was appointed by the military and political chief of Greece in 1829. Two of the ablest leaders, Gen. Church and Demetrius Ypsilanti, absolutely refused to recognize his authority. After the assassination of his brother he assumed the government as chairman of the board of regency, and was elected president by the national convention assembled at Argos in Dec. 1831. The Russian government assured him of its sympathies, and he was recognized by the London conference of the allied powers. A few weeks later the opposition became so powerful that the great powers retracted their former action and compelled him to resign. He left Greece for St. Petersburg, April 13, 1832, taking the corpse of his brother with him.

CAPONNIÈRE, in fortification, a work constructed on the sole of the ditch of the fortress, in order to flank that ditch by its fire. The inventor of this kind of work is unknown; it is said to have been proposed in Italy as early as 1496, and it is certain that the Italian engineer, Pallavicini, constructed similar works in 1506. The first systematic application of caponnières for the defence of a ditch occurs in the work of Albert Dürer, the German painter, on fortification, printed in 1527. He applies them in his circular and quadrangular fortifications in the same manner as they are now actually constructed; and, indeed, it is hard to believe that Montalembert composed his polygonal system entirely without knowledge of Dürer's work. The idea, however, was neglected for more than 2½ centuries, during which the bastionary system was the only one recognized. In 1777 the French cavalry general, the Marquis de Montalembert, published the 2d volume of his work on the science of fortification, developing the polygonal system, in which the whole flanking defences of the ditch consist of powerful commated batteries constructed on its sole, in the middle of each front or side of the polygon.

CAPPADOCIA, an ancient province of Asia Minor, between lat. 37° 16' and 39° 28' N., and long. 32° 50' 18" and 39° E. It was conquered by the Persians under Cyrus. After the era of Alexander the Great, it was ruled by independent kings until A. D. 17, when it was reduced to a Roman province by Tiberius. Christianity was early introduced into Cappadocia, as we learn by the 1st general epistle of St. Paul. Under the Persians or Macedonians, the province was divided into 2 satrapies, Cappadocia ad Pontum and Cappadocia ad Taurum, called afterward by the Romans Cappadocia Magna, also

a simply. The chief town of the lat-  
zaca, afterward Cæsarea, and the  
as celebrated for its fine pastures and  
r breed of horses, mules, and sheep.

ured the fate of the eastern  
all fell into the power of the Turks,  
possession it still remains, forming  
eral modern eyalets of Asiatic Turkey.  
, NEWCOME, an English dissenting  
orn in Leeds, Feb. 21, 1782, died at  
. 24, 1800. He studied with Dr. Ai-  
worth, and Dr. Doddridge at North-  
nd at the university of Glasgow.  
h Dr. Doddridge, he became satisfied  
lences of revealed religion, of which  
rmerly entertained doubts. At the  
of Glasgow he made the acquaint-  
lam Smith, Moore, Cullen, and Black.  
he pastoral charge of the congrega-  
Saviour's Gate, York, for 40 years.  
e author of several theological works.  
LL, the name of a French Protestant  
ed for the many learned theologians  
which it produced from the 15th to  
entury.—One of the most prominent  
was LOUIS CAPPELL, born near Sedan,  
585, died at Saumur, June 18, 1658.  
l a high reputation as professor of  
oriental languages at the university  
r, and as an exegetical and critical  
le is principally known, however, as  
t with the Buxtorfs, in the Masoretic  
roversy. The correctness of his views  
bject has been settled by the general  
f Hebrew scholars that the present  
pointing cannot be carried back be-  
1th century.

JA, the Capraria and Ægilon of the  
small volcanic island of the Mediter-  
tween the N. point of Corsica and  
of Tuscany. It is about 15 m. in cir-  
e; its surface is generally mountain-  
ts principal product is wine. Wild  
abound in the mountains. It has  
its own name, with a safe harbor.  
is island was taken from Corsica by  
se, and it is now a part of the prov-  
noa. Pop. about 2,500.

.RA, GIOVANNI BATTISTA, an Italian  
d statesman, born in Bologna, May  
died in Paris, June 21, 1810. He was  
rs old when appointed by Pope Ben-  
vice-legate at Ravenna. He was  
papal nuncio successively at Cologne,  
nd Vienna, and in 1792 was made

In 1800 he was created bishop of  
ing been appointed, in 1801, legate  
the French republic, he succeeded  
ing the terms of the concordat, which  
ed upon Sept. 18, 1801; and in April,  
document was promulgated at Paris,  
oman Catholic form of worship was  
d at the church of Notre Dame with  
ldor. In May, 1805, he crowned Na-  
filan asking of Italy. Having return-  
is legate of the pope, he died there.

OAPRI (anc. *Caprea*), a small and rocky  
Neapolitan island, in the Mediterranean, S. of  
the entrance to the bay of Naples, noted in his-  
tory as the place where Augustus resided dur-  
ing his illness, and where Tiberius spent the  
last 10 years of his life. It is still celebrated  
for the beauty of its climate, which makes it a  
favorite resort for invalids, especially for those  
suffering from chronic bronchitis. The island  
is about 9 miles in circumference, and sur-  
rounded by steep and inaccessible cliffs. Total  
pop. about 4,000, comprising 2 small towns,  
Anacapri and the port of Oapri. The latter is  
the see of a bishop, and contains a cathedral  
and some other churches; pop. about 2,600.  
Between the 2 mountains of limestone (the  
highest of which is Monte Solaro, rising nearly  
1,800 feet above the sea), of which the island  
consists, lies a fertile valley, which yields grain,  
olives, grapes, and other fruits. The inhab-  
itants are engaged in the production of the fa-  
mous red and white Oapri wines and of oil, in  
fishing and in the pursuits of the sea, and in  
catching quails, vast numbers of which are  
caught every spring and autumn on their passage  
from and to Africa. Remains of several of the 12  
villas erected by Tiberius in various parts of the  
island are still to be seen, and other relics of an-  
tiquity have been excavated here. The French  
under Gen. Lamarque surprised this island, then  
in the occupation of the English under Sir Hud-  
son Lowe (Oct. 1808), and compelled them to  
capitulate within 15 days after the invasion.

OAPRICOIO, in music, literally a whim or  
caprice, a term applied to that species of com-  
position in which the composer arbitrarily de-  
viates from the customary forms and gives free  
play to his fancy.

OAPRICORN, a sign of the zodiac, which the  
sun enters at the winter solstice in December;  
also a constellation formerly in this sign (see  
AQUARIUS). The tropic of Capricorn is the  
southern boundary of the torrid zone, at which  
the sun is vertical at noon only once a year,  
the day he enters Capricorn, usually Dec. 20  
or 21.

CAPRIOLE, a peculiar leap made by a horse  
without advancing, in which, when at its  
height, he throws out his hind legs with a  
jerk, keeping them parallel and near together,  
and showing the shoes. It differs in the last  
particular from the croupade, and from the  
balotade in the jerking out of the legs. It is  
the most difficult of all the high airs in the  
manège.

CAPSA, an ancient city in northern Africa,  
in an oasis of the desert. Its site is occupied  
by the modern Gafsa, 74 miles W. of Oabea.  
Tradition ascribed its foundation to the Libyan  
Hercules. It was destroyed by Marius in the  
war with Jugurtha, but afterward rebuilt.

OAPSICUM, a genus of plants, from 4 species  
of which are obtained as many varieties of the  
so-called cayenne pepper. The name capsicum  
is also applied to the product itself. The genus  
is of the *solanaceæ* or nightshade family, and

has no relation with the family of *piperacea*, which furnishes the real peppers. The 4 species referred to are *C. annuum*, *C. frutescens*, *C. cerasiforme*, and *C. grossum*. The first 2 only are of importance. The first is an annual herbaceous plant, remarkable for its hardy nature. A native of tropical countries, in which it thrives luxuriantly in dry and poor soils, it is also cultivated in almost all parts of the world. It grows 2 or 3 feet high, and bears a pod or seed-vessel, called also its berry, of ovate or conical form, recurved at the end, green when immature, but bright scarlet or orange when it ripens in October. It is used in the green state for pickling, and in medicine when ripe and dried, and is ground to powder to make cayenne pepper. In England the dried berries kept in the shops are called chillies. This variety is imported from the West Indies, and is supplied from our own gardens. Its product is hot and pungent, but without aroma. *C. frutescens* furnishes the so-called bird or Guinea pepper, a hotter and more pungent and better flavored article, and to some extent aromatic. The plant is a shrub, best known in the East Indies. The berries are scarcely an inch long, and only a line or two broad. They contain each about a dozen reniform seeds.—The active principle of capsicum, called *capsicine*, is a volatile liquid, thick when cold, but very fluid before it disappears by heat in fumes. The vapor is so pungent, that what is produced from  $\frac{1}{2}$  a grain, when dispersed in a large room, will cause all present to cough and sneeze. It is obtained by digesting the alcoholic extract in ether and evaporating.—Cayenne is largely employed as a condiment, acting as a stimulant and aiding digestion. For these properties it is administered as a medicine; and it is also highly useful as a gargle in malignant scarlatina. In the West Indies, for violent cases of this disease, the preparation for both uses is to infuse for an hour in a pint of boiling vinegar and water 2 tablespoonfuls of the powdered pepper with a teaspoonful of common salt. When cold, the liquid is strained, and given in the dose of a tablespoonful every half hour. Capsicum is said to relieve the nausea of sea-sickness. It is also employed externally as a rubefacient and stimulant, either in the form of a cataplasm, lotion, or tincture.—The commercial cayenne is subject to gross adulterations. Red lead and vermilion, or sulphuret of mercury, are the worst materials introduced, and cases of poisoning are reported from this cause, both the lead and mercury having the property of aggregating in the system when taken in small quantities. They are added to keep up the color, which gradually fades with the age of the capsicum, also to increase the weight, and to disguise the other ingredients. Ochres are also employed for similar purposes; salt also, to improve the color and add to the weight. Ground rice and turmeric are more harmless additions.

CAPSTAN, a machine used on board vessels for weighing anchor, and for other operations

requiring a heavy pull. It consists of a horizontal axle with holes around which are placed bars, called handspikes, around which the rope is passed 2 or 8 times around the axle. When men take hold of the loose end of the rope, they give a tension and keep the capstan clear of it. Others take hold of the handspikes and walk around with them. The power of a man thus applied is about equal to the traction of 25 lbs., hanging over a pulley, at a velocity of 3 feet per second. The capstan is rarely used, and when the handspikes are removed, it occupies on deck but a few square feet. A greater number of men may work at a capstan than at a horizontal axle, and they can act much more rapidly, as they have simply to walk around pushing the handspikes forward; whereas with a horizontal apparatus, as often as it is turned a quarter of a circle, they have to take out the bars on which they act and insert them in new holes before they can act again. Since the year 1820, numerous patents have been issued for improved capstans. Most of them consist in making the head separate from the axle, and adapting gearing, which may be connected or disconnected at will, to vary the power of the machine as occasions require. Another improvement, consequent upon the adoption of chain cables, consists in making the lower portion of the capstan the exact counterpart of the chain, so that each link as it comes up enters the corresponding recess, and the chain is thus held more firmly with half a ton than it would be with 3 tons around a smooth surface. The capstan is an instrument of the past, and has already been superseded by the steam winch on board of a large number of steamships, and it seems probable that before long each sailing vessel will have to be provided with a small steam engine for doing heavy work of the sort.

CAPSULE, a name given by botanists to any kind of dry seedvessel containing many cells and seeds, such as poppy heads, &c.; the word is derived from the Latin *capsula*, a small box. The pods of peas and beans, &c., are called capsules, as well as the seed-containing vessels or fruit of many other families of plants. A capsule usually opens by valves; and hence different varieties have been named bivalve, trivalve, quadrivalve, and multivalve. The parts of a capsule are: 1, the valves, ribs, or divisions which form the outward shell, and shield the fruit externally; 2, the partition walls, which form different cells internally; 3, the axis or columella, which unites the seeds with the internal parts of the capsule; 4, the cells occupied by the seeds; 5, the proper receptacle of each seed; and 6, the seeds contained within the capsule. According to the number of internal partitions in a capsule, they have been named unilocular, bilocular, trilocular, multilocular. Capsular seedvessels are generally dry and hard when ripe; and in this respect they are unlike the pulpy fruit of apples, plums, &c., or the juicy oranges and lemons. All fruits, however, are merely seedvessels, and the name capsule

plied to all dry, hard seedvessels, of particular forms and families of

**LES, GELATINE**, little bags made of gelatine, designed for holding doses of medicines, so that all being swallowed, their taste may not be perceived. One is to take a cylinder of hard wood, rounded off at one end, and  $\frac{1}{2}$  of an inch in diameter, and dip the end first into a saturated solution of soap in alcohol to the depth of  $\frac{1}{2}$  inch. When the soap has hardened on the wood, it is to be dipped into a hot solution of gelatine, and this according to the thickness of deposit desired. This is to be slipped off when it has hardened; and the process is to be repeated to procure another bag for a cover to the first one. When one is filled with the medicine, the other is applied upon it, and the 2 are tightly secured together by going over the line of junction with a camel's hair brush moistened with hot water. For other methods see *Journal de pharmacie et de chimie*, vol. xvii. p. 204, and the American "Journal of Pharmacy," vol. p. 20.

**CAPTAIN**, the rank designating a commander of a company in infantry, or of a squadron or troop in cavalry, or the chief officer of a ship of war. In most continental armies the rank of captain is considered subaltern; in the British army they form an intermediate rank between the field officer and the subaltern, the latter term comprising those commissioned officers only whose rank does not imply a distant and constant command. In the U. S. army the captain is responsible for the arms, ammunition, clothing, &c., of the company under his command. The duties of a captain in the navy are very comprehensive, and his post is one of great responsibility. In the British service he is next in rank to a lieutenant-colonel in the army, until the expiration of 8 years from the date of his commission, when he takes rank with a full colonel.

In the old French service he was forbidden to leave his ship under pain of death, and was to die with it rather than let it fall into the hands of an enemy. The title of captain is also applied to masters of merchant or passenger vessels, and to various petty officers on ships of line, as captain of the fore-castle, of the main, of the main and fore tops, &c. The word is of Italian origin, meaning a man who is at the head of something, and in this sense it is often used as synonymous with a general-in-chief, especially as regards his qualities of command.

**CAPUA**, or **CAPOA**, a fortified town, in the kingdom of Naples, in the province of Terra di Lavoro, lying in a plain on the left bank of the Volturno, 15 m. N. W. of Naples, on the high road to Rome, and 10 m. from the Mediterranean; pop. about 10,000. The present Capua does not stand on the site of the Capua of antiquity. The remains of Roman times are numer-

ous. The cathedral and the church *dell'Annunziata* are splendid edifices, and contain many antique bas-reliefs built in with their walls. In 1808 the town suffered considerably from an earthquake.—The ancient Capua lay at a distance of 2 m. from the modern city. Its origin and early history are obscure. In 848 B. C., when threatened by the Samnites, the citizens called in the aid of the Romans, and were shortly afterward compelled to acknowledge the supremacy of Rome. It successfully resisted Pyrrhus, king of Epirus, but after the battle of Cannæ (216 B. C.), the popular party deserted Rome and opened the gates to the Carthaginian general. The winter spent by the Carthaginian troops in Capua demoralized them greatly, and was considered by the Romans to be the main cause of Hannibal's ultimate defeat. For the extravagance and effeminacy of its inhabitants, Capua bore a reputation similar to Sybaris and Sardis. It was famous for its manufactory of perfumes, with which the *unguentarii* or perfumers of Capua supplied the whole empire of the West. It was early celebrated for its gladiatorial exhibitions, and from Lentulus's school of gladiators in this city Spartacus, the rebel leader in the servile war, first broke loose with 70 companions. In 211 the Romans again entered Capua. All the senators were put to death, 800 of the nobles were thrown into dungeons, and the middle class of citizens were removed to a distance from their native place. The local magistracies were abolished, and a Roman prefect was appointed to rule over the city. During the social war the Capuans manifested the most unshaken fidelity to Rome, and were, as a reward therefor, re-endowed with many of their ancient municipal privileges. Julius Cæsar procured the passage of a law during his consulship, 59 B. C., in accordance with which 20,000 Roman citizens were settled in the environs of Capua. This circumstance conferred a new era of prosperity upon the city.—The barbarian invasions were fatal to old Capua. Genseric and his Vandals devastated it in A. D. 456. Narses restored it, but it sank again after the conquests of the Longobards in southern Italy. It was finally destroyed by the Saracens, A. D. 840, who reduced it to ashes. A few years afterward, Bishop Landulfus induced the inhabitants to return and establish a new city on the site of the ancient Casilinum. This was the origin of the modern Capua. The ruins of the amphitheatre, built of tiles and faced with white marble, are an object of attraction to antiquaries. The remains of old Capua have been described by Rinaldo in his *Memorie storiche della città di Capua*, Naples, 1758, and in Ruca's *Vetere Capua*, Naples, 1828. The site of old Capua is now occupied by the large village of Santa Maria di Capua, or Santa Maria Maggiore.

**CAPUCHIN**, a religious congregation belonging to the Franciscan order, instituted by Matteo Baschi. Matteo was desirous of

practising greater poverty than was required by the strict rule of the order of St. Francis. Having observed that a painting of St. Francis represented him with the hood of the habit of a different shape from that usually worn by the order, he made one like it and wore it, about the year 1525. This being condemned by his superiors as a novelty, he had recourse to Pope Clement VII., who gave him permission to wear the hood, and also permitted those who wished to imitate him to form a congregation. In 1528, Clement VII. gave them further permission to wear the habit and also a beard. They were to reside in solitary places, and live as hermits. When they commenced wearing their peculiar dress through the streets of Camerino, the children commenced calling after them *Capuccini*, whence they were styled Capuchins. The rules of the order are very strict: they are obliged to recite the canonical hours without singing, and the matins are to be said at midnight; an hour is to be spent every morning and evening in mental prayer and in silence; their food is of the simplest kind, one kind of meat only being allowed, and on fast days they are only allowed a kind of cheese called *cotta*. They are not allowed to wear any covering for their head, and their habit is of the coarsest description; nor are any ornaments of gold or silver allowed in their churches. In 1624, Urban VIII. caused a new church to be built for them at Rome, near the Barberini palace, he being a member of that family, and in 1631 the Capuchins took possession of it. The church contains the famous painting of St. Michael the archangel, by Guido. This congregation has supplied many missionaries to Asia, Africa, and America, and a great number of cardinals and bishops. It has produced also many illustrious writers.

**CAPUDAN PASHA**, is the title of the chief commander, or great admiral, of the Turkish navy, who is at the same time supervisor of the naval stores and establishments, and governor of the Turkish islands of the archipelago, and of some of the coasts of the empire. He is pasha of 3 tails, makes all the appointments in the navy, is a member of the divan. Every summer he makes an excursion with the fleet to the archipelago to exercise the ships, and levy the taxes. The title is probably a Turkish imitation of the Italian *Capitano*, like many other terms now usual in the Levant, and derived from the times of Genoese and Venetian influence in those regions.

**CAPUT MORTUUM**, a Latin name given by the old chemists to the fixed residue of distillation and sublimation, symbolized in alchemical writings by a death's head and cross bones.

**CARABINE**, or **CARBINE**, a short barrelled musket adapted to the use of cavalry. In order to admit of its being easily loaded on horseback, the barrel ought not to be more than 2 feet 6 inches long, unless it be breech-loading; and to be easily managed with one hand only, its weight must be less than that of an infantry musket.

The bore, too, is

that of the

have either

first case, its

to that of the common

will exceed it in precision

In the British service, the

bored carabines; in the Russian

horse all have rifled carabines, while

cuirassiers  $\frac{1}{2}$  have rifled, and the

smooth barrels to their carabines. They

too, in some services (French and

cially), carry carabines; those of the

on the principle of the new Enfield

abine-firing was at one time the

of cavalry fighting, but now it

used on outpost duty, and with

mishng. In French military works, the

pression *carabine* always means an infantry

rifle, while for a cavalry carabine the

*mousqueton* is adopted. Several improvements

in breech-loading carabines have recently been

made in the United States, and submitted

trial to an ordnance board at West Point (Jan.

1858).

**CARABOBO**, a province of Venezuela bounded by the Caribbean sea, and by the provinces of Caracas, Varinas, Truxillo, and Coro: area 8,148 sq. m., pop. about 100,000. Its capital city is Valencia, but the province takes its name from a village 20 miles S. W. of the capital, where a battle was fought June 24, 1811, which secured the independence of Colombia. It is intersected by the head-streams of the Rio Portuguesa, and produces coffee, cocoa, wheat, tobacco, and sugar.

**CARACALLA**, **MARCUS AURELIUS ANTONINUS**, a Roman emperor, born at Lyons A. D. 168, died in 217. He was originally called *Basiniana*, but received the nickname of Caracalla, from a favorite Gallic tunic which he introduced into Rome. On the death of his father Severus at York in 211, he ascended the throne with his brother Geta, but soon caused the murder of the latter, and, according to Dio, of 20,000 Romans who were his partisans, among whom was the jurist Papinian. He multiplied extortions in order to purchase the favor of the soldiery, gave the right of Roman citizenship to all free men of the empire in order to impose taxes upon their estates, and admitted Egyptians to the senate. He made unimportant expeditions against the Gauls, Goths, and Parthians, and at Alexandria took revenge for some injuries by a general massacre of the inhabitants. He was assassinated near Edessa on his way to Carrhae at the instigation of Macrinus, the pretorian prefect.

**CARACAS**, a province of the republic of Venezuela, bounded N. by the Caribbean sea, E. by Barcelona, W. by Carabobo, Cogedea, and Barinas, and S. by Apure and Guiana; area 44,264 sq. m., pop. about 800,000. The N. part is in general mountainous, but toward the S. the surface expands into vast and fertile plains. The province is divided into 16 cantons, of

which the canton of Caracas is the richest and most populous.—The capital of the above-described province and of the republic of Venezuela, Caracas, is situated 11 m. S. S. E. of La Guayra, in lat. 10° 30' N., long. 66° 34' W. Its site is the declivity of a mountain nearly 3,000 feet above the sea. The streets are wide and well built, intersect each other at right angles, and are generally supplied with fountains. The houses are usually faced with stucco, are sometimes richly decorated, and have often terraced roofs. There are several spacious squares, the largest of which is the Plaza Mayor, or Great square, where the fish, fruit, and vegetable market is held. The principal public edifices are the churches, the convents, and the university, which was founded in 1778. The cathedral is a very large structure, and the church of Alta Gracia a very beautiful one. The Catucho feeds the fountains which supply the city with water. The exports consist principally of cacao, for which Caracas is celebrated, of cotton, indigo, coffee, tobacco, hides, and live cattle. The trade is carried on through the neighboring port of La Guayra, and the shipping of 1854-'55 comprised 45,450 tons, including import and export. For further commercial and for historical information, see VENEZUELA.—Caracas is the seat of the president, and of the chief judicial and ecclesiastical authorities of Venezuela. The schools, supported by the city at an annual expense of \$40,000, are well attended. The celebrated Bolivar was a native of Caracas, and in 1842 his remains were interred here. The town was visited by an earthquake in 1812, by which about 12,000 persons are said to have perished. The earthquake of 1826 also contributed to diminish the population and to injure the town. It has, however, been rebuilt since, and the population is believed to have risen again to about 50,000, and by some authorities even to 68,000.

CARACCIOLI. I. DOMENICO, marquis, an Italian statesman, born in Naples in 1715, died in 1789. He was ambassador to the court of France in 1770, and became acquainted with D'Alembert, Diderot, Condorcet, and other encyclopædists, who entertained for him a high regard. In 1781 he was appointed viceroy in Sicily, where he distinguished himself principally by the abolition of torture. II. FRANCESCO, prince, a Neapolitan admiral, born at Naples in 1748, died in 1799. He repeatedly commanded the Neapolitan fleet, when acting in concert with the English against the French, and thus became acquainted with Nelson. In 1798 he served under Nelson; and in 1799, with the consent of the king, he repaired to Naples, in order to prevent the confiscation of his property, and was appointed commander-in-chief of the navy of the "Parthenopean Republic." Although he reluctantly accepted this place, he successfully opposed, with a few ships, the landing planned by the combined English and Sicilian fleets. Naples

having been retaken, he was arrested, and in violation of the capitulation by which the officers of the late republican government were allowed to leave the country unmolested, he was brought a prisoner on board Nelson's ship, the Thunderer, arraigned before a Sicilian court-martial, and condemned to be hung. A request was presented in his name to the English admiral for a less ignominious mode of death; but Nelson, through the influence of Lady Hamilton, declined acceding to it, and, a few moments later, his old companion in arms was suspended from the yard arm of a Neapolitan frigate.

CARACOLE, in horsemanship, is an oblique tread, traced out in a semi-round, changing from one hand to the other, without a regular ground. When horses advance to charge in battle, they sometimes ride up in caracoles to perplex the enemy, and make them doubtful whether they are about to take them in the front or in the flank. Caracole is a Spanish word, and in that language signifies the motion that a squadron of horse make when upon an engagement. The first rank have no sooner fired their pistols than they divide and open into two half ranks, the one wheeling to the right and the other to the left, along the wings of the body, to the rear. Every rank observes the same order of firing; and turning or wheeling from the front to the rear is called a caracole. This is the same movement which is performed by infantry, in street firing on the advance, without making any halt, in column, the men who wheel off loading as they counter-march to the rear. To caracole is to go round in the form of a half circle.

CARACTACUS, king of the Silures, an ancient British people who inhabited Wales, died A. D. 54. He resisted the Romans for 9 years. Ostorius, sent by the emperor Claudius, at length defeated him and took his wife and children prisoners. He himself took refuge with Cartismandua, queen of the Brigantes (York), who delivered him for a reward to the emperor. His proud bearing and noble and pathetic speech so won the admiration of Agrippina and Claudius that they pardoned him and discharged him with presents.

CARAFÀ, MICHELE, an Italian musical composer, born in Naples, Nov. 17, 1787. He studied music under the best masters of his day, but served in the army until 1814, when he retired with the appointment of major, and devoted himself to music as a profession. In 1814 first appeared the opera *Il Vascello d'Occidente*, soon followed by *La Gelosia Corretta*, *Gabriele di Vergi*, *Ifigenia in Tauride*, *Masaniello*, &c., &c. The *Solitaire* and *Masaniello* are considered his best. His compositions are noted for sweetness, simplicity, and naturalness of melody, and correctness and elegance of instrumentation.

CARAGA, a province of the Spanish Philippines, forming the N. E. division of the island of Mindanao. It is bounded S. by the territories

of the independent sultan of Mindana, and E. and W. by the sea; area 8,400 sq. m., pop. 42,000. This province is one of the poorest under the Spanish dominion; it has generally a sterile soil, and abounds in waste marsh lands. Its forests are, however, reputed to be of great value, consisting chiefly of the finest ship timber trees, especially the teak, which is not found elsewhere in the Philippine islands. Great numbers of wild buffaloes, hogs, deer, civet cats, and other musk-producing animals are found in the forests. Considerable quantities of gold are found in alluvial deposits on the Batoan river and its tributaries. The bulk of the population is of the Bisaya race; but there are several wild tribes: one called Mandaya, which have very fair complexions, and Spanish writers say that they are a mixed race descended from Malay women and some shipwrecked Dutchmen; another tribe called Tagabaloyo are said by the same authorities to be descended from shipwrecked Japanese, and native Mindanese women. There is a negrito race called Mamamanna. The inhabitants subsist chiefly upon sago, fish, and roots of spontaneous growth. The Spanish are rapidly effecting a beneficent change in the condition of the semi-civilized and savage population of this province. Its only export at present is a small quantity of gold dust.

**CARAITES**, or **KARAITES**, a sect among the Jews, whose origin is very uncertain. Some Jews say that they are the same as the Sadducees, because they do not receive the traditions of the rabbins; others that they are reformed Sadducees, because they accept the doctrines of immortality of the soul, resurrection of the body, paradise and hell, which the Sadducees rejected. Others consider the Caraites to be the same as the doctors of the law mentioned in the New Testament. The Caraites themselves date their origin from the captivity of the 10 tribes by Shalmanezzer. Wolf attributes their origin to a massacre among the Jewish doctors under Alexander Jannæus, about 100 B. C. Steinschneider, in his "History of Jewish Literature," places the origin of Caraim as a literary development in Judaism from A. D. 750 to A. D. 900, and says that it sustained a very important part in the reformation of Jewish literature. He, however, admits a Caraitic tendency in Judaism of a much earlier date. The present principal seat of the Caraites is in the Crimea and in Austrian Galicia. They always worship toward the S., because they say that Shalmanezzer carried the 10 tribes from which they date their origin to the N., so that they must turn to the S. to face Jerusalem. The Caraites deny the oral law to have come from Moses, reject the cabalistic and chimerical interpretations of the rabbins, and observe the feasts with greater rigor than other Jews.

**CARAMAN**, or **KARAMAN** (anc. *Laranda*), a town of Asiatic Turkey, in the eyalet of Caramania, at the foot of Mt. Taurus, lat.  $37^{\circ} 12'$  N., long.  $33^{\circ} 5'$  E.; pop. about 12,000. It con-

tains the

mosque with prior by rows of 4 temples of modern nian church, and a Turkish by a wall which Coarse blue cotton are manufactured.—Little ancient Laranda, on or near the present town was founded in century by Karaman Oglu, a Turkish whom it was named. It Turkish kingdom until the mania by Bajazet II. in 1 government was removed to Konieh, and the glory of Caraman began to fade. Though residing at Konieh, the pasha takes his title from this place. The name of Laranda or Larenda is still used by the Christian inhabitants of the country and in the firmans of the sublime porte.

**CARAMANIA**, or **KARAMANIA**, also **KARAMAN**, a Turkish province or eyalet in Asia Minor, between lat.  $37^{\circ}$  and  $39^{\circ} 40'$  N., long.  $36^{\circ} 50'$  and  $38^{\circ} 50'$  E., including ancient Lycania and a portion of Phrygia Major, Galatia, and Cappadocia, bounded W. and N. by the eyalets of Anatolia and Sivas, S. by Adana, and E. by Marash, famous for its genial climate and for its tobacco, silk, cotton, sesamum, honey, wax, and excellent fruit. The soil is rich and dry, yielding abundant harvests; the vine and fig-tree, the laurel, myrtle, and clematis, and many odoriferous shrubs, flourish in profusion. The Taurus range traverses the entire length of Caramania, and forests of oaks and pines 100 feet high cover the mountain. The principal rivers are the Kizil-Irmak and the Sibon. In the S. W. are a large number of small lakes; also mineral springs. Fish abound in the rivers and the numerous small streams of the country. The inhabitants are mainly devoted to agricultural pursuits, particularly to the rearing of live stock, the vast plains affording abundant pasturage. The villages of the shepherds are composed of huts, covered with skins; most other houses are of earth, or of brick baked in the sun, and present a miserable appearance. Trade embraces, beside the products named wool, horse and camel hair, gum tragacanth, which abounds in the mountainous districts, and various other commodities. The exports are carried on by caravans or through the nearest shipping ports. Capital, Konieh. Area 27,952 sq. m.; pop. about 1,000,000, comprising a great number of Armenians, Greeks, and Jews, but chiefly nomadic Turcomans.

**CARAMNASSA**, a river in the presidency of Bengal. It is a tributary of the Ganges, and is of interest on account of a superstition attached to it. A certain rajah once killed a Brahmin, and married his own stepmother. Nothing could expunge his crimes, save ablation in a collection of all the holy waters of the world. A charitable saint undertook the task;

the aggregation of fluid a river was which was so entirely exhausted of its powers, that ever afterward it was mnassa (deprived of virtue). The

ful, if obliged to pass this bale- n, that its waters shall not touch him; wise all the merits acquired by a series ons and other pious practices would be washed out.

MEL, a black porous substance, pro- om sugar heated to a temperature 400° and 430°. It is also formed casting of coffee and chicory. It is adulterate coffee, imparting to it and to rages substituted for it bitterness and t is also used for coloring wines.

T, the name of an imaginary weight, by amonds are rated; and also a term used essing the fineness or purity of gold. is supposed to be divided into 24 parts rats, and its fineness is reckoned accord- e number of these which are pure gold. carats fine is 20 parts of pure gold al- th 4 of some other metal. The term so long in use that its origin is very

Some suppose it to be derived from k *keparion*, a fruit corresponding to the *liqua*; whence the Arab word *kyrat*,

Bruce, in his "Travels," describes a met with in a famous gold mart of hich was used as a weight from remote and which was called *kuara*. They e in gravity from the time the pods and being much alike they were in imes carried to India for weighing t. As usually employed by jewellers, ht of a carat is 4 imaginary grains, of  $\frac{1}{16}$  are required to counterbalance 72 oy.

VAGGIO, MICHEL ANGELO DA. See DA CARAVAGGIO.

VAN AND CARAVANSARY, a party ers or pilgrims in the East, and an or their lodging or entertainment. ay be said to be 2 distinct kinds of

1. Commercial caravans, formed of s who are crossing the deserts or places for traffic; and 2, religious cara- posed of pilgrims going to some sacred worship. They often consist of 1,000 and several thousand camels. They

or the general superintendence of a whom each caravan is divided into a of *cottors* or platoons. There are 5 rs: 1, the officer of the march; 2,

campment; 3, of the servants and , of the baggage; and 5, the pay- A military escort and a *hybeer* or tend each caravan. These caravans

ostly by night in the hot season, and oy do so are guided by means of fires

carried in iron boxes, supported on s, and borne at the head of each cottor ny. Each cottor has a box differing rom the others, and so the boxes serve rds to enable each pilgrim to know his

cottor. When a caravan is to encamp, the cottor standards are sent forward and stationed, and each cottor on coming up must pitch around its own standard. The places of all, both in the encampment and march, are permanently allotted by the bashè. It was evidently to such a commercial caravan, made up of Ishmaelites and Midianites, that Joseph was sold by his brethren. The religious caravans are now principally made up of Mohammedans who make the pilgrimage to Mecca. Burckhardt, the great eastern traveler, who was at Mt. Arafat when the Syrian and Egyptian caravans for Mecca were encamped at its base, has given a very interesting description of the scene. From the top of the mountain he counted 8,000 tents, while he says that far the greater number of the pilgrims were, like himself, tentless. The number of pilgrims he estimated at 70,000 in these 2 caravans, and the number of languages they spoke at least at 40. The wife of Mehemet Ali required 500 camels to transport her baggage in the pilgrimage.—The CARAVANSARIES of pilgrims are generally the rudest structures consistent with the purpose of protection. They are mostly the creations of charity on the part of the inhabitants of the desert. Sometimes they are kept to receive travellers for pay, when they are more generously arranged and furnished. The first mention we have of such inns may be that in which the children of Jacob stopped to rest and feed their asses on their return to Egypt. The caravansaries for the accommodation of the commercial caravans are not provided by charity, but are erected at the expense of the merchants themselves.

CARAVELLAS, a seaport town of Brazil, on the bay of Caravellas, which opens into the Atlantic. It is a well-built place, and its harbor is the most frequented of any in the province. The productions of the province are exported hence to Rio, Bahia, and Pernambuco. Pop. of the district, 5,000.

CARAWAY, the fruit or seeds of the *carum carui*, a small biennial plant, which grows wild in the meadows and pastures of central and northern Europe, and is cultivated in gardens, as it is in this country. The root, which in the cultivated plant resembles the parsnip, is used for food in the north of Europe. The seeds mature the second year of the growth of the plant. They are collected by mowing the stalks and threshing, which, from the smallness of the seeds, should be done on a cloth. They are valued for their medicinal properties, for which, or rather perhaps for their pleasant aromatic flavor, they are introduced into the cakes called seed-cakes, and into some kinds of sugar plums. In Europe they are used in confectionary, to flavor liquors and cakes, and also bread, cheese, and other articles of food. Their medicinal action is to stimulate the digestive organs, and remove flatulency; they are used also to aid or modify the action of other medicines. An essential oil, *oleum cari*, is prepared by distillation

of the seeds, which possesses their properties, and is used to flavor medicines, and correct their nauseating and griping effects. An oily liquid, named *carvacrol*, is obtained by distilling oil of caraway with hydrated phosphoric acid, and turning the liquid back into the retort until it ceases to have the odor of caraway. It has the property of affording immediate relief to the tooth-ache when introduced into the tooth. Caraway seed is imported from Europe, and is also supplied in part from our own gardens. It is largely cultivated in Essex and Suffolk, England, being sown on old pasture lands, together with coriander and teasle. The coriander ripens the first year, the caraway in the summer, and the teasle in the autumn of the second year.

**CARBAZOTIC ACID**, called also **CARBOAZOTIC** and **PIORIC ACID**, is obtained by the action of an excess of nitric on carbolic acid, and also upon indigo, gum benzoin, resin, aloes, and similar vegetable substances. It is a very bitter substance, crystallizing in yellow prisms, which are volatile, and fuse into a brownish yellow oil. Its chemical formula is  $C_{12}H_8N_2O_8$ . It has been lately introduced to notice, is said to be beneficial in intermittent fevers, and is considered valuable in the dyeing of silks and woollens. It is thought that if the grass tree, or black bay gum from Australia, were employed and treated with nitric acid, as proposed by Dr. Stenhouse, the price of this article might be greatly reduced. In 1851, in Paris, where it was manufactured, it was sold for \$2 40 per lb. The yellow and green colors produced by this substance are described as very beautiful, and not liable to fade by exposure to the air, as is the case with those colors obtained from vegetable dyes.

**CARBOHYDROGENS**, a term applied by some chemists to combinations of carbon and hydrogen, including a large number of liquid organic substances, as some oils of wines and non-oxygenous volatile oils; also among solid bodies the substance caoutchouc, and among gaseous bodies the carburetted hydrogen or coal gas and olefiant gas. But by others it is used to designate those compounds in which the amount of carbon and hydrogen in each differs by an equal number of atoms, or by a multiple number, and which, on this account, are said to be homologous. Their physical characters are likewise varied by their amounts of carbon and hydrogen present, which affect particularly their boiling point. Thus,

	B. P.
Pyroxylic spirit, $C_2H_4O_2$ , boils at	183.2° F.
Alcohol, $C_2H_6O$ , " "	172.4° "
Potato spirit oil, $C_{10}H_{12}O_2$ , " "	275° "

Every 2 atoms of CH raise the boiling point  $84^\circ 2''$ . This is the use of the term, as given by Dr. Thomson.

**CARBOLIC ACID**. In the distillation of the tar obtained from bituminous matters among the first products obtained at temperatures between  $800^\circ$  and  $400^\circ$ , are some light essential oils, which collect upon the surface of the

water in the c  
oils with twice  
and decomposing by  
is obtained heavier  
and having some of the prop  
which it much resembles.  
 $C_{12}H_8O$ , HO, which is that of hyd  
phenyl. Its specific gravity is 1.1  
ing point  $368^\circ$  F. Its taste is burn  
caustic. It acts upon the skin, and is per  
sonous; like creosote, it is used for the tooth  
ache. It crystallizes in needles, which sink in  
water. The same substance is also obtained by  
distilling the *castoreum Canadense*. Carbolic acid  
possesses in a high degree the antiseptic prop  
erties of creosote, and is found to be useful in  
preventing the putrefaction of animal matter.  
By the action of nitric acid it is converted into a  
substance called carbazotic acid, which is an im  
portant dyeing material. It is of further use in  
dyeing and calico printing, by preserving from  
decomposition the extracts of tanning mat  
ters, which are liable to ferment and be convert  
ed into sugar and gallic acids.

**CARBON** (Lat. *carbo*, coal), represented by the symbol C, one of the most common and important substances in nature, occurring in a great variety of forms in the vegetable, animal and mineral kingdoms, in the two first named being by far the most considerable element. The charcoal prepared from many substances belonging to these presents it pure; but the diamond is crystallized carbon, contaminated, when colorless, by no foreign admixture. In this form carbon possesses the most brilliant lustre, and a hardness unsurpassed, which is represented upon the mineralogical scale by the highest number, 10. (See **DIAMOND**.) Carbon is remarkable for its allotropic character, presenting itself under various forms, while still in a state of purity. Beside those named, graphite may be regarded as one of its forms, the trace of other substances met with in its purest qualities being considered accidental; also gas carbon, the extremely hard substance which is deposited upon the inner surface of gas retorts; and lampblack, the soot deposited by highly combustible bodies, as they are imperfectly consumed. When 1 atom of carbon is combined with 2 atoms of oxygen, it forms the compound, carbonic acid gas, an essential constituent of solid limestones and other carbonates, and, in a gaseous form, of the atmospheric air. Its compounds with hydrogen are called carbhydrogens; they occur in gaseous, solid, and liquid forms. The chemical equivalent of carbon is 6, established by Dumas by the diamond, when consumed in a stream of oxygen gas, combining with this in the proportion of 6 parts to 16. Carbon resists the influence of many reagents which powerfully affect other bodies; acids and alkalies at ordinary temperatures have no effect upon it in its denser forms; but charcoal is oxidized in boiling nitric acid. Neither is it affected by the strongest heat attainable in furnaces, provided it be protected

action of air or oxygen. Pieces of are found enclosed in the cinders of furnace, which have been for 24 hours in the intense heat of its interior, being ores and limestones, but promote way from exposure to the oxygen. The only indications of volatilization which it can be made to exhibit, exposing it in a vacuum to the heat of Sen's battery of several hundred pairs in 5 or 6 series as to form 100 pairs times the ordinary size. It is then and collects on the sides of the in the form of a black crystalline powder. The effect is produced, but more slowly, by exposing it to the heat, instead of in a vacuum, as with which carbon does not combine at the same temperature charcoal may be heated, welded, and fused, becoming graphite when the heat is continued. It is converted into graphite. Diamond is not affected. The production of gas which somewhat resembles this volatilization, will be seen at the close of this article. We have also furnished some hints as to the origin of graphite. No substance, except crystallized boron, is more unaltered by heat, in which other bodies undergo chemical change. It is taken up by cast iron, when these are fused in contact with it, and its presence in cast iron and steel imparts them the qualities that distinguish malleable iron. The most valuable uses of carbon in practical uses are its strong affinity for oxygen at high temperatures, and its power of resisting in some of its forms the action of furnaces. The former quality gives to many of its varieties their value as combustibles (see FUEL), and it also renders it the most powerful reducing agent of the metals; for which purpose, as in the blast, generating heat by its combustion, it is used in smelting furnaces, bloomeries, &c. The appearance as carbonic acid gas adds to the convenience of its use for this purpose. Its refractory character admirably adapts it as a material for crucibles; and when in the form of paste of pure charcoal ground very finely, and applied as a lining to earthen crucibles, it serves not merely to protect the contents from injurious contact with the outer vessel, but also furnishes to these the reducing agent or flux. The black tiles or blue pots, are in part composed of graphite, which, when prepared by grinding and mixing with refractory earths, resists even the action of the blast in the blast furnaces. Other useful purposes of carbon are considered in treating of it in which this is the principal element. **ONE BLACK, CHARCOAL, COAL, COKE, FUEL, GRAPHITE, &c.**—The peculiar form of carbon already referred to as being obtained in gas retorts, and collected in crevices in the interior, possesses a metallic lustre, and of mammillary structure, resulting

from the aggregation of the vesicles of which it is composed. It is sometimes fibrous, resembling graphite; its specific gravity is 1.76. Its hardness exceeds that of any other form of carbon, except the diamond. It is burned with difficulty in high heat when exposed to currents of air—a property which renders it useful for the illuminating points of the voltaic light. Its origin is commonly attributed to a deposition of carbon from olefiant gas,  $C_2H_4$ , which is generated in the distillation of bituminous coal, and is converted by parting with 2 atoms of carbon into marsh gas or the light carburet of hydrogen,  $CH_4$ , used for illumination. Dr. Hayes, from the fact that olefiant gas alone deposits carbon in the form of lampblack, and that only when mixed with bituminous vapors is the vesicular, brilliant form obtained, is led to believe that the olefiant gas is not the agent that produces this sublimate, but that it is a product of changes caused by heat in vapors of hydrocarbons. The bituminous vapors unmixed, as those of paraffine and other fatty hydrocarbons, affording it also, closely resembling that found in the retorts, confirms this view. Dr. Hayes considers that its mode of formation may be applied to explain that of the natural graphitic compounds; and that these, and in general, sublimates composed of vesicular forms, presenting laminae, under this view, become a class of bodies which owe their forms to the transporting power of vapors in motion.

**CARBON**, a county in the E. part of Pennsylvania, area about 400 sq. m., pop. about 17,000, formed in 1848 out of part of Northampton county, and named Carbon from its mines of anthracite. It is a mountainous district, made up of parallel ridges running in a N. E. and S. W. direction. The largest of these is the Blue or Kittatinny mountain, which bounds the county on the S. E. The coal mines are in the smaller ridges N. W. of this. Of these, Mauch Chunk, at the eastern termination of the southern anthracite coal field, is the most important. At the top of Summit mountain the beds have been opened and worked like a quarry, the coal lying in a mass not less than 50 feet thick. The Hazleton and Beaver Meadow mines are in the N. W. corner of the county. Anthracite is the principal production of the county. It is transported by railroads from the mines to the Lehigh river, and thence by slackwater navigation and canal, and also by the Lehigh Valley railroad, down the Lehigh to the Delaware river at Easton. The Lehigh river traverses the county across the line of its ridges; but the mines are only on its W. side, and from 6 to 10 miles or more distant. The yield of the mines in this county is about one-sixth of the whole production of anthracite. Capital, Mauch Chunk; pop. about 4,000.

**CARBONARI** (Ital. *carbonajo*, charcoal-burner), a secret political society, which became notorious in Italy about 1818, though it had existed long before. According to some accounts, the first carbonari were Scotch charcoal-burners, patron-

ized by Francis I., who made their acquaintance while on a hunting excursion to Scotland. Again, it is said that German charcoal-burners established such societies in the beginning of the 16th century. However uncertain the precise origin of the society, it is probable that the occupation of charcoal-burning offered inducements to mysterious associations; and at the beginning of the present century, when the Neapolitan republicans, alike opposed to the usurpation of Murat and the rule of Ferdinand, took refuge in the Abruzzi mountains, they organized, under the leadership of Capobianca, a carbonari society, adopting charcoal as a symbol of purification, and accepting the general basis of the traditional coal-burners' ritual with a view of wreaking revenge upon oppressors, or, as they expressed it in their symbolic motto: "Revenge upon the wolves who devour the lambs." Queen Caroline of Naples, and the Sardinian minister Maghella, are mentioned, in addition to Capobianca, as the prime movers of the Abruzzi league of carbonari. The little Neapolitan town of Lanciano, in the province of Abruzzo Citra, numbered as many as 1,200 carbonari, and all over the Abruzzi new societies were formed, whose political influence became so marked, that Prince Moliterni was despatched to them by Ferdinand with a view of securing their co-operation against the French. But the carbonari, although their unwillingness to bear any foreign yoke had originally given rise to their association, leaned more and more toward republicanism; and, especially when the expelled dynasty was reinstated upon the throne of Naples, they assumed an attitude of uncompromising hostility against monarchy. From 30,000 members, the number of carbonari all over Italy had been swelled in one month (March, 1820) to the enormous figure of nearly 700,000, including many persons of education and good family. A great number, however, became carbonari under the impression that the society was a masonic lodge, unconnected with politics.—The place where the carbonari assembled was called the *baracca*, or collier's hut; the country round their gatherings was a forest; the interior of the *baracca* was called the *tendita*, from the sale of coals which the colliers are supposed to carry on in their huts. Each province contained a large number of such *baracche* or huts, and the union of the different provincial huts constituted "a republic." The leading huts were called *alte tendite*, and had their headquarters at Naples and Salerno. Their attempt to centralize all the huts under one and the same head proved fruitless, although some of the carbonari republics presented an imposing character of unity. There was, for instance, the republic of western Lucania, in the mountainous coast district of the province of Principato Citra, which embraced 182 *baracche* or huts, and had its head-quarters at Salerno, the chief town of the province.—The growing influence of the order alarmed the conservative governments of Europe, especially the Bourbons,

as, since 1819, the carbonari had put into contact with French republicans. The trial of the Corsican Guerini, who, once with the decree of the *alta corte*, stabbed a fellow-member for having the secrets of the society, added to the movement. Previous to 1819, the carbonari in France took their rise principally from the *charbonneries*, which flourished in the Franche Comté. But the movement of the Italian carbonari, especially the carbonari in Sicily and Sardinia, gave a frisson to the French fraternity, and under the influence of Buchez and Flottard, a new society was set on foot in Paris, in an obscure house in the rue Copeau; and in Buchez's house, in the rue Vieille du Temple, a military academy was established for the benefit of the society. Men like Voyer d'Argenson, Lafayette, Lafitte, Dupont de l'Eure, Barthe, Teste, Boinvilliers, and others, of mark, joined the movement, while the ritual of the Abruzzi carbonari underwent a sole modification, that while the Italian carbonari had only the one superior division called the *tendita*, the French carbonari classed themselves in 4 *centes*, viz.: *centes particulières*, *centes nationales*, *hautes centes*, and *centes supérieures*. Admission to the *centes* was also surrounded by greater formalities in France, although, in admission, the principle of equality was maintained, and, like the Italians, the French carbonari greeted each other as *bons cousins*. The rites of the French carbonari are secret. The faintest whisper of the secrets of the society to outsiders—or *païens*, as outsiders are called—constitutes treason, and, as punishable with death. No written communications are permitted. The *centes* communicate with the other *centes* by means of special agents, who exhibit their authority by the presentation of the half of a *carbone*, which is cut in a peculiar manner, and which corresponds with the other half of the *carbone* for this particular purpose of identifying the other *centes* with whom they are to communicate. Among the many signs, and passwords of the French carbonari, the passwords *speranza*, *fede*, *carità* have a special and peculiarly sacred meaning. The rites of the *centes supérieures* were followed by the sacrifices which a carbonaro made for the interests and principles of the society, and were boundless. In 1819 there were 20,000 carbonari in Paris, and the carbonari associations were known under the names of *la Washington*, *la Victorieuse*, *la Sincère*, *la Réussite*, *les Amis de la Liberté*, *la Westermann*, &c. But there were no *centes*, as no *vente* could have more than a few members. From Sept. 1820, until Sept. 1821, a separate committee sat at Paris for military affairs, as the army contained a large number of carbonari. In 1821 the government officially informed that the society numbered 25 out of the 86 departments of France.

time the number of carbonari in France could have been less than 600,000, with more than 10,000 in Italy, and perhaps 200,000 scattered over Spain, Portugal, &c. The troubles of 1820 were ascribed to their influence, which became very formidable by the martyr spirit displayed by the carbonari in the trials arising from the racy of Aug. 18, 1820, and again in 1822. The *congrès national* of the carbonari, which had its head-quarters at Paris, seemed for a time omnipotent. All the insurrectionary movements from 1819 to 1822 were laid at their door. One of the cardinal points in the creed of the French carbonari was to make Paris the political focus of the world. After the July revolution of 1830, many carbonari gave in their allegiance to Louis Philippe; but at that time a new *charbonnerie démocratique* was founded by Buonarrotti upon the theories of Babeuf, which lasted, who was a prominent member, expounded in his *Projet d'une constitution républicaine*. The last public vestige of a carbonari association was in 1841 in southern France.

**CARBONATES.** The combinations of carbonic acid with bases are very numerous, notwithstanding that the acid itself is one of the most feeble, and is easily expelled with effervescence by nearly all the other acids. Merely red heat alone expels it from all the carbonates, except those of potassa, soda, lithia, barytes, and strontian; and the last 2 are decomposed by an intense white heat. In contact with coal heated to redness, all are decomposed, a metal or an oxide is produced. The carbonates of ammonia, soda, and potassa alone are readily dissolved in water; the others are insoluble, or nearly so; but if free carbonic acid is present, their solubility is increased. The simple carbonates, or combinations of 1 equivalent of carbonic acid and 1 equivalent of the base, may be regarded as neutral salts. The proportion of oxygen in the acid and base of these is as 2 to 1. Combinations of 2 equivalents of the acid to 1 of the base are bicarbonates, and those of 2 of the base to 1 of the acids are called dicarbonates. Compounds we met with in nature of double carbonates, dolomite and baryto-calcite—the former a compound of carbonate of lime and carbonate of magnesia, and the latter of carbonate of barytes and carbonate of lime. Among the most important carbonates are those of lime, soda, and ammonia, the last 3 of which we found treated of under the names of their bases. Carbonate of lime, in its purest natural form, is the mineral calcareous spar (see). Chalk is also composed of it, and is the principal ingredient in the limestones and marbles. It consists of 1 atom of lime, the chemical equivalent of which is 28, and 1 atom of carbonic acid, 22. These making 50, the percentage of each ingredient is consequently 56 its equivalent number. So abundantly used is this compound among the strata that it forms the crust of the earth, that it has been supposed to constitute about  $\frac{1}{4}$  their

substance. It is recognized by its moderate degree of hardness, being easily scratched with a knife to a white powder, whatever the color of the stone may be, and by its effervescing with acids. Heated to redness, its carbonic acid gas escapes, and quicklime remains. But it may be subjected to intense heat in strong close vessels, so that it may even be melted, and still retain its original composition.

**CARBONDALE**, a city of Luzerne co., Penn., at the head of Lackawanna valley, and near the source of the Lackawanna river. A railroad 17 m. long connects it with Honesdale. The Lackawanna valley is extremely rich in beds of coal, which, in the vicinity of Carbondale, are 20 feet thick. The mines are worked by the Delaware and Hudson canal company, who take out annually about 500,000 tons. The coal is drawn up inclined planes by steam engines, to a height of 850 feet; thence it is conveyed by railroad to Honesdale; and from Honesdale, by the Delaware and Hudson canal, to the Hudson river. The city was incorporated in 1851, and is rapidly increasing. Pop. in 1854, 7,500.

**CARBONIC ACID**, a gas discovered in 1757 by Dr. Black, and called by him *fixed air*. He detected it in limestone and magnesia, from which he found it could be expelled by heat and the acids, and also noticed that it was produced by combustion, fermentation, and breathing. Lavoisier demonstrated its composition synthetically by burning carbon in oxygen, and obtaining this product. It was analyzed by Smithson Tennant, by causing it, as evolved from heated limestone, to be decomposed by the vapor of phosphorus passing over it; carbon was deposited in a light black powder; the oxygen combined with the phosphorus, producing phosphoric acid, which by its union with the lime converted this into a phosphate. The composition of this gas is,

Carbon, 1 atom.....	= 6, or per cent.....	27.27
Oxygen, 2 atoms.....	= 16, " " .....	72.73

Its chemical equivalent then = 22, and it is represented by the symbol  $\text{CO}_2$ . The volume of the oxygen it contains is the same as that of the compound produced. Compared with air, its weight is as 1.524 to 1. It may be poured almost like water from one jar into another, displacing the air before mixing with it, as may be shown by its extinguishing a light placed in the lower vessel. It is without color, but has a decided sour taste, and a pungent odor. Its feeble acid reaction is shown in transiently changing litmus paper red. Flame is immediately extinguished when it is mixed with air in the proportion of 1 part to 4. Unmixed with air, it is entirely irrespirable; it is rejected with violent spasms of the glottis. In the atmosphere it is universally diffused in proportion exceeding  $\frac{1}{1000}$  part by measure, even at the greatest height reached by man. It is this small quantity which furnishes to growing plants the carbon of their solid structures; and as the supply is diminished by

this enormous absorption, the combustion and decay of organic bodies, and the respiration of animals, ever make good the deficiency. The great weight of this gas tends to keep it in the low places where it is generated, though, like other gases, it has also the tendency to mix with atmospheric air. Hence it is always prudent, before descending into badly ventilated wells, to let a candle down to prove the presence or absence of the gas. It is related by Dr. Christison, that cases have occurred of men becoming instantly insensible, even when the light burned. This may be owing to some peculiarity of the mixture of gases not understood, probably to the presence of carbonic oxide; for it has happened to the writer to descend several times into air so impure, that a candle could not possibly be lighted in it, and to remain with another person long enough to make many ineffectual attempts to ignite it, and this with no other effect than a severe headache. In mines it is a very common thing for the men to continue their work in an atmosphere so foul, that their candles go out, and are then relighted from the fire still in the wick, by swinging them quickly through the air, when they burn a little while and go out, and are again relighted in the same way. The son of Berthollet, the chemist, who destroyed himself by inhaling the fumes from burning charcoal, writing down his sensations at the time, remarked that the candle was soon extinguished. The lamp continued to burn, and was flickering, as he became himself powerless to record more. Persons made insensible by inhaling this gas, may be restored by immediately dashing cold water over them. This is the practice pursued at the famous Grotto del Cane at Naples, in order to restore the dogs, which, for the gratification of visitors, are exposed to the fumes of the gas, into which they are dipped as into an invisible bath. Such natural accumulations of this gas are not very rare, though much that is evolved from the earth is absorbed by the waters it meets, some of which are almost as highly charged with it as the "mineral" waters of the shops. It is stated by Dr. Thomson that the Upas valley of Java, so celebrated for its pestilential vapors, is not altogether fabulous, but that these vapors are derived from quite another source than the poisonous Upas tree. From a deep dell immense quantities of carbonic acid are evolved, which contaminate the lower strata of the air throughout the valley, and sufficiently account for the remains of men and animals which lie strewn over it. When the air of wells is too impure for men to descend, it may be driven out by any of the ordinary modes of ventilation, by agitating the column for some time in any way, by the explosion of powder; or, as suggested and practised by Prof. Hubbard, by lowering a vessel containing ignited charcoal nearly to the bottom. Incandescent coals have the property of absorbing many times their bulk of this gas, and when cooled they may be raised up, reignited,

and lowered again. A well in which would not burn within 26 feet of the surface was thus purified in the course of an hour.—Water readily absorbs carbonic acid, which it may be freed by boiling. It is being placed under the exhausted receiver of an air pump. Under the ordinary pressure of the atmosphere, and at a temperature of 60° it takes up its own volume of the gas, and as the pressure is increased, so much of the gas is forced into the water. The gas is pungent, pleasant, slightly acid taste, and sparkling effervescence seen in bottles in which it has been generated. It is obtained from powdered carbonate of lime or limestone, exposed to the action of hydrochloric or sulphuric acid, is used to saturate mineral waters for drinking. It is generated in strong vessels, capable of sustaining a pressure of 5 atmospheres or more. This is the "soda water" or "soda water" of the apothecaries, both improper names, as it contains neither soda nor other mineral substance. In contact with the air, the greater part of the gas is absorbed, and when thoroughly expelled by boiling, the water has an insipid taste. Pure lime detects its presence in solution, becomes immediately turbid, as the lime seizes the gas, and is converted into an insoluble carbonate. But if the gas is greatly diluted, a portion of this is redissolved. A solution of limestone soluble in water impregnated with this gas, but metallic bodies are also acted upon by it, and converted into carbonates. Some of these are soluble and possess poisonous qualities, regard should always be had to the use of leaden pipes and vessels used for conveying and containing water, which by long use may be impregnated with the gas. The copper gas generators of the druggists should especially be protected by a lining of glass or porcelain.—By subjecting carbonic acid to powerful pressure, Prof. Faraday obtained it in a liquid form. Thilorier repeated the experiments, and condensed the gas into a solid form like snow. The pressure used for this purpose is that of 20 atmospheres. Sulphuric acid is made upon bicarbonate of soda in strong calenders, and the gas is passed through metallic pipes into a reservoir placed in an ice-mixture. In this it solidifies. In early experiments of Thilorier, in a public lecture at Paris, the apparatus exploded under the enormous pressure, and one of the assistants was so much injured that he died in a few hours. It was by Thilorier, that when the liquid gas was allowed to escape into a brass box, and a small tube, the cold produced by the rapid evaporation of one portion was so intense that it served to congeal the remainder. This snowy product, remelted and recondensed, becomes a clear crystalline solid like ice, but having a low conducting power, it is not so good as the liquid gas; and though its r

more than  $100^{\circ}$  below the zero point of Reaumur's thermometer, it does not cause a sensation of cold. Mixed with ether and condensed under an exhausted receiver, the greatest degree of cold ever known was produced by Prof. Faraday. The spirit thermometer sunk to  $166^{\circ}$  below zero. With the production of such a congealing temperature and application of pressures varying from 27 to 300 atmospheres, Prof. Faraday succeeded in condensing several of the compound gases into white and colorless transparent solids. An experiment of the intense cold produced by the condensation in the open air of the solid gas and given in the freezing of 10 pounds of water in less than 8 minutes, by contact with the solid substances upon its surface. A large lump of ice was kept for a minute in a red-hot iron, and a pound of mercury was immediately afterward frozen with it. The vapor evolved from the solid gas possesses a higher temperature than that from any other substance; like the vapor from other bodies, it is condensed by lowering instead of raising the temperature. This interesting subject may be more fully treated in Brande's "Manual of Chemistry."

**CARBONIC OXIDE**, or **OXIDE OF CARBON**, containing one equivalent less of oxygen than carbonic acid, being a combination of 1 atom each of carbon and oxygen—hence designated by the symbol CO. It contains 42.9 per cent. of carbon and 57.1 per cent. of oxygen. Its specific gravity compared with air is 0.967. It is a product of imperfect combustion, and is generated in large fires in close furnaces in enormous quantities. It is mixed with carbonic acid and other products of combustion. By the introduction of atmospheric air to it while highly condensed it combines with another atom of oxygen, burning with a blue flame and becoming carbonic acid. It is visible by night under the form of a white change, as it meets the air when coming from the tops of chimneys of large furnaces indicating imperfect combustion within the furnace, and consequent want of economy in the use of the fuel. In the large iron establishments, this gas is utilized by causing it to pass through the fresh air admitted under the cylinders of the steam engines, or in the chambers connected for heating the air blown into the cylinders. If the flow of the gases be obstructed, the flow is irregular, explosions may result from an admission of oxygen or of atmospheric air to them when highly heated. When mixed with pure oxygen, carbonic oxide is by a spark converted into carbonic acid with explosion. The oxide may be re-obtained by passing the carbonic acid through a tube containing red-hot charcoal or metallic iron which take up 1 atom of oxygen.—Carbonic oxide is a colorless gas, without smell or taste, more irrespirable and poisonous than carbonic acid. Its inhalation as it issues from furnaces sometimes causes immediate asphyxia in workmen. It undergoes no change like

carbonic acid under heavy pressures at the lowest temperatures; nor is it taken up by water like this gas, nor does it produce similar acid reactions in changing vegetable blues to red. Heat and electricity produce no change in it when alone; when mixed with carbonic acid, it may be separated and obtained pure by introducing quicklime or potash, which absorbs the carbonic acid. The mixture free from other gases is obtained by treating the bioxalate of potash hot with concentrated sulphuric acid. Other processes also are given in chemical works.

**CARBONIFEROUS** (Lat. *carbo*, coal, and *fero*, to bear), usually applied to the group of rocks between the old and new red sandstones in which the great deposits of mineral coal are mostly found. The carboniferous group has the same signification as coal formation.

**CARBUNCLE**, an unhealthy inflammation of the surface, accompanied by a sloughing of a circumscribed portion of the subcutaneous cellular tissue; of the same nature as a boil, only deeper seated and of larger size. It begins by a hard, tense swelling, of a livid and shining appearance, and with severe burning pain; it is generally accompanied by feverish symptoms, often of considerable severity, and is slow in its progress; in from 1 to 3 weeks the skin becomes thin and perforated by numerous holes, from which issues a thin whitish discharge; the ulcers finally unite into one of large size, at the bottom of which is seen a soft grayish mass, the slough of the cellular tissue, with a very disagreeable odor; this slough or core is soon separated, leaving a deep excavation, with thin edges, and surrounded by a livid skin. The swelling may vary in size from 1 to 6 inches in diameter, and is usually found upon the back, nape of the neck, and nates; it may occur also on the shoulders, chest, lower jaw, and lower extremities. It is most common in adults and old persons, whose constitutions have been broken down by intemperance, exposure, hard study, or mental anxiety; it is always an evidence of a vitiated state of the blood and of derangement of the digestive organs. It sometimes appears to be the means of removing morbid matters from the system. If of large size, in an enfeebled constitution, or on or near the head, a carbuncle may endanger life. The local treatment which has been found the best, is to make free incisions into the tumor, to allow the escape of the discharge and sloughs, to relieve the engorged tissues by the loss of blood, and to excite them to healthy suppuration and granulation; warm and stimulating poultices, ointments, and lotions, hasten the cure. At the same time, the diseased secretions of the alimentary canal should be removed by purgatives; the strength supported by nourishing diet, bark, and the mineral acids; irritability calmed by small doses of opium; and the blood renovated by a judicious exhibition of preparations of iron.—In mineralogy, the name of a precious stone much valued

by the ancients. It was probably a blood-red garnet.

**CARBURETS**, or **CARBIDES**, combinations of carbon with the metals and simple bodies, as steel and cast iron, which are carburets of iron. The most interesting of these is the volatile liquid, sometimes called carburet of sulphur and alcohol of sulphur, but now known by the name of bisulphuret of carbon. It may conveniently be described in this place. It is a heavy, clear fluid, of a strong fetid odor, and very inflammable. Its specific gravity is 1.293, its boiling point  $118^{\circ}$ . It evaporates with great rapidity, absorbing so much heat, that quicksilver may be frozen in a tube surrounded with lint wet in this substance, and placed in the exhausted receiver of an air pump. Its composition is carbon 1 atom and sulphur 2 atoms, or per cent. 15.8 of carbon and 84.2 of sulphur. The mode of preparing it is, to pass the vapor of sulphur over charcoal heated to redness in a tube, and collect the fluid which goes over in water. It should be redistilled to free it from moisture and excess of sulphur. This substance is particularly interesting for its strong solvent power, and the readiness with which it passes into vapor. Its volatility has suggested its use for engines, as a substitute for water, and working models have been made to run by it. The design was to condense it, and use the same material over and over. It is used now principally for varnishes, and for dissolving caoutchouc, &c. In medicine it is employed as a stimulant, to excite the natural secretions of the skin, kidneys, &c., to increase the animal warmth, accelerate the pulse, &c. Recently it has been successfully applied to indolent tumors, and to the glands of the ear to remove deafness.

**CARBURETTED HYDROGEN**. Two compounds of carbon and hydrogen are designated by this term, one called the light carburetted hydrogen, and the other olefiant gas. The former is also known as the fire-damp of the miners, marsh gas, &c. It was observed in coal mines as early as 1640. Dr. Franklin, in 1774, called the attention of Priestley to an inflammable gas obtained in this country by stirring stagnant pools. It was first accurately described by Drs. Dalton and Thomson in 1811. It is a colorless gas, without taste or smell, and neither of acid nor alkaline properties. Its composition is carbon 1 atom, hydrogen 2 atoms,  $\text{C H}_2$ , or per cent., C—75, H—25. Its weight, compared with that of air, is 0.555. Burning bodies immersed in it are extinguished, and it does not support respiration. It is highly inflammable, burning with a yellow flame; but it requires a high heat to ignite it. United with oxygen or atmospheric air in due proportion, a compound is produced which explodes with the electric spark or the approach of flame. The mixture of air to produce an explosion may be from 7 to 14 times that of the gas. Water and carbonic acid gas result from the chemical change. In mines of bituminous coal this gas is generated abundantly, and it also issues from

**CARBURIS**, **MARINO**, count, a Greek engi-  
neer, born at the beginning of the 18th century,  
at Argostoli, Cephalonia, died 1782. He received  
a thorough education at the university of Bologna;  
being banished for some youthful but criminal  
folly from Greece, he assumed the name of  
Lascari, and entered the Russian service. The  
empress Catharine II. appointed him lieutenant-  
colonel of the corps of engineers, and intrusted  
him with the construction of the work connect-  
ed with the statue intended for Peter the Great.  
Carburis procured a monolith consisting of a  
block of granite from the gulf of Finland, 21  
feet high, 40 feet long, and 27 feet in width.  
This block was imbedded 15 feet deep in a  
swamp. The difficulty was how to extricate it  
and convey it to St. Petersburg. Carburis in-  
vented a machine for this purpose, and under  
his superintendence the block was safely shipped  
to the shores of the Neva, and from thence  
transported by land to the public square of St.

urg, where it was erected Sept. 30, 1769. The emperor of Russia appointed him director of a military academy for young noblemen connected with the engineering department of the empire. But receiving permission to return home, he settled in Cephalonia. Here he was employed in the cultivation of indigo, and in the growth of sugar and of American cotton. After 4 years he was assassinated by some of his laborers. The wife of Carburis was also wounded, but survived her husband.

The mechanical apparatus used by Carburis in the construction of the Russian monolith was, at the request of the French government, placed in the *conservatoire des arts et métiers*.

CARCAJENTE, a town of Spain, in the province of Valencia, in a beautiful plain on the coast. It is handsome and prosperous, and has many linen and woollen manufactories. Many remains have been discovered in its ruins. A battle between the Spaniards and the French took place near this town, July 13, 1813, in which the former were defeated. Pop. in 1856, 12,280.

CARCASS, a shell filled with inflammable material, the flame of which issues through holes, and is so violent that it can scarcely be extinguished. They are thrown from ships, howitzers, and guns, in the same way as common shells, and burn from 8 to 10 minutes. The composition is either melted over a fire and poured hot into the shell, or it is pressed into a compact mass by the aid of liquid, and then crammed into the shell. The holes are stopped with corks or wooden plugs, through which a tube, filled with fuse, is introduced, and a lighted match, or a small fire, passes into the shell. Formerly carcasses were cast with a partition or diaphragm, like the present shrapnell shells, the bottom part being destined to receive a full charge of gunpowder; but this composition is now done away with. Another kind of carcasses was formerly in use, constructed of a light ball, on two circular iron hoops crossing each other at right angles, over which a canvas was spread, thus forming an impenetrable spheroidal body, which was filled with a composition, containing mostly gunpowder and pitch. These carcasses, however, have been abandoned, because their great lightness made them almost impossible to throw them to any distance, or with any precision. The composition for filling our modern carcasses varies considerably, but they each and all consist chiefly of saltpetre and sulphur, mixed with a resinous substance. Thus the Prussian service uses 100 parts saltpetre, 25 parts sulphur, 7 parts gunpowder, and 33 parts colophony. The French use saltpetre 100 parts, sulphur 40 parts, resin 30 parts, antimony 10 parts, tallow 10 parts, turpentine 10 parts. Carcasses are used in bombardments, and sometimes in shipping, though in this latter use they have been almost entirely superseded by red-hot shot, which is easier prepared, of greater weight, and of far more incendiary effect.

CARCASSONNE, a city of France, chief town of the department of Aude, 488 m. S. of Paris, on the river Aude, which divides it into 2 parts, the old city and the new, joined by a bridge of 10 arches. The new town is well built, with broad streets intersecting each other at right angles. Carcassonne is an important manufacturing and commercial centre, and contains large woollen factories, producing a fine cloth, highly esteemed for its brilliant dyes, which is especially exported to the Levant, Barbary, and South America. No place, perhaps, in France, has preserved to a greater extent the aspect of a fortress of the middle ages. It is enclosed by double walls, flanked with towers, and protected by a strong castle. Carcassonne is supposed to have been the ancient Carcasum, which was the chief town of the Volcae Tectosages, who were conquered by the Romans. The Visigoths probably built the inner line of the walls, and part of the castle. These fortifications, however, did not prevent the storming of the town by the Saracens. Although subsequently strengthened by the warlike viscounts of Carcassonne, and defended by the heroic Raymond Roger, they could not long withstand the crusade against the Albigenses. In 1247, Carcassonne submitted to the king of France. It is the seat of a bishopric, has tribunals of primary jurisdiction and commerce, a departmental college, and other learned institutions. In the church of St. Nazaire is the tomb of Simon de Montfort. Pop. in 1856, 19,915.

CARD PLAYING. Like the game of chess, cards are supposed to be of Asiatic origin, and indeed seem to have been based upon the same warlike associations, some of the figures of chess having appeared also in the cards used in the Orient. In Hindostan cards were called *tachahar-tass*, signifying 4 crowns or 4 kings, the popular name being *taj* or *tas*. The Chinese call their cards *che-pas* or paper tickets; they have 80 cards in a pack, 8 suits of 9 cards each, and 8 single cards which are superior to all the others.—The most ancient form of cards is still preserved in the figures of the cards used in the French game of *tarots*. This name is derived from the Arabic, and the game was originally connected with religious, necromantic, and scientific associations. The ancient terms for cards, as *naipes* in Spain and *naibi* in Italy, are also of Arabic etymology, and signify fortune-telling. In all probability, cards were introduced into Europe by Arabs, Jews, and other oriental races, before the 18th century, the Saracens especially having made the game popular in Spain and Italy, whence the taste for it spread into Germany, France, and England. The first historical evidence of its existence in Germany presents itself before 1275, when a minute in the town hall of Augsburg records the fact that "Rudolph I. amused himself with playing cards and other games." The use of cards in Italy is mentioned as early as 1299. The first authentic record in France occurs in 1393, when in the official accounts of Charles Poupert, treasurer

of the royal household, an item of expenditure appears for *trois jeux de cartes* presented to Charles VI. by Jacquemin Gringonneur, an artist. As early as the 15th century, an active trade in cards sprung up in Germany, and was chiefly carried on at Nuremberg, Augsburg, and Ulm, the demand from France, England, Italy, Spain, and other countries producing great prosperity among the manufacturers. The most eminent manufacturer of cards in France in the 16th century was Jean Volay. In England the manufacture of cards flourished especially under Elizabeth. But no sooner had cards come to be generally used in Europe, than they were prohibited by several governments, partly from moral considerations, the first games, as *Landsknecht* in Germany, *lansquenet* and *piquet* in France, being games of chance; partly from considerations of political economy, as in England, where the importation of foreign cards was considered injurious to the prosperity of home manufacturers. The prohibition, however, only tended to increase the taste for cards. In England, under Richard III. and Henry VII., card playing grew in favor. The latter monarch was very fond of the game, and his daughter Margaret was found playing cards by James IV. of Scotland, when he came to woo her. The popularity which cards gradually obtained in England may be inferred from the fact that political pamphlets under the name of "Bloody Games of Cards," and kindred titles, appeared at the commencement of the civil war against Charles I. One of the most striking publications of this kind was one in 1660 on the royal game of ombre. In "Pepys's Diary," under the date of Feb. 17, 1667, it is stated that on Sabbath evenings he found "the Queene, the Duchesse of York, and another or two, at cards, with the rooms full of ladies and great men."—The marks upon the suits of cards are supposed to have been originally intended for a symbolical representation of the 4 different classes of society, hearts representing, according to this supposition, the clergy, spades the nobility (It. *spada*, a sword), clubs the serfs, and diamonds the citizens. The figures originated with military and historical associations. So we find the kings in the first French cards representing the monarchies of the Jews, Greeks, Romans, and French. The queens, knaves, the ace, and the number of the cards, were based upon similar ideas; but many changes and modifications have taken place at various periods, according to the customs and tastes of different countries. Breitkopf's *Versuch des Ursprungs der Spielkarten* is one of the most profound dissertations on the subject. Singer's "Researches into the History of Playing Cards" was published in London in 1816; Leber's *Etudes historiques sur les cartes à jouer*, in Paris in 1842; and Chatto's "Facts and Speculations on the Origin and History of Playing Cards," in London in 1848.

CARDAMOM, a name rather vaguely applied in commerce to the aromatic seeds of various East India plants, of the natural order

*zingiberacea*. *amomi* was of Family *damom* of Sumatra, *mum cardamomum* variety from Madagascar *cardamom*, but other varieties Ceylon are also called by the some authorities. The *macopœias*, and the best known is that from Malabar. It is the product *renealmia cardamomum* of Roscoe, a perennial plant with a tuberous root, growing wild in the mountains, and cultivated by the natives. The seeds are exported in their capsules, which are also aromatic, but are rejected in the use of the article for medicine. Cardamom seeds are valued for their aromatic and pungent qualities, and are much used to flavor various medicines and cordials. The natives of the East use them as a condiment. One variety, known as *grains of paradise*, Guinea grains, and Malaguetta pepper, is imported in seeds from Guinea, and also from Demerara, where the negroes have introduced and now cultivate it. The plant is probably the *amomum Melegueta* of Roscoe, though one of the varieties found in the English markets is from the *A. grana paradisi* of Sir J. E. Smith. The negroes use the seeds as seasoning for food, and in Africa they are highly esteemed among spices. Their flavor is highly pungent and peppery. In England they find an extensive use for giving a factitious strength to adulterated gin and other liquors, and frequently appear as one of the ingredients of the so-called "gin flavorings." (See GIN.) They are also administered as medicine in veterinary practice.

CARDAN, GIROLAMO, an Italian savant and physician, the illegitimate son of a jurist and physician of Milan, born at Pavia, Sept. 24, 1501, died in Rome, Sept. 21, 1576. When young he joined the order of St. Francis, but abandoned it afterward. Devoting himself to the study of medicine and philosophy, he obtained his degree of M.D. in 1525, practised his profession for some time, and successively officiated as professor of mathematics and medicine at Pavia and Bologna. He published a treatise on mathematics, *Arithmetica magna*, which gained for him a high reputation in that branch of science; while in the medical profession he ranked equally high, the king of Denmark offering him, but in vain, a professorship. While on a visit to Scotland, he was hailed as a great physician, and said to have effected some famous cures. Pecuniary embarrassments driving him away from Bologna, he repaired in 1570 to Rome, where he spent the rest of his life, honored with the friendship of Gregory XIII., who settled a pension on him, and caused him to be admitted a member of the college of physicians. He was noted as much for his eccentricities as for his abilities, and his writings as well as his life present a curious combination of industry and absurdity. His most famous treatise, *De Subtilitate*, is divided into 21 books, which are taken up by the various branches of scientific, philosophical

ysical speculations; the 16th book, treats of science in general, and advocates the propriety of beginning education of the young by teaching geometry, being the most sensible. A son of his works is considered the best (10 vols. fol., 1663).

CARDENAS, one of the administrative divisions of the Spanish West Indies, department of the Spanish West Indies, of Cuba. Area 106 sq. leagues.

Pop. 86,361, including 27,521 whites, 50,000 colored, and 55,016 slaves.—CARDENAS, chief town of the division, situated on the coast of the island, pop. in 1858, 10 m. E. by S. of Havana, is connected by rail and telegraph with Havana, Matanzas, and is, after Havana, Matanzas, and Pinar del Rio, the most important commercial port of Cuba, the custom-house in 1854 having been \$409,000. The harbor of Cardenas has 5 to 6 fathoms of water for anchorage. At its entrance is a fixed light. The filibuster Lopez effected his escape in 1850, and toward the end of the year isolated the town, burning the theatre, the custom-house, and the powder-magazine, property to the extent of \$1,000,000.

LUDOVICO, called also CIGOLI, a painter, born at the castle of Cigoli, in 1559, died in 1613. He was the pupil of di Titi, but was indebted for his knowledge to the careful study of the works of Correggio. His "St. Peter healing the Lame" has been considered as inferior only to the "Transfiguration" of Raphael. His other most esteemed works are "St. Jerome" and the "Conversion of St. Paul" at Rome, the "Stoning of St. Peter" and the "Trinity," "Mary Magdalene," and "The Homo," at Florence. He enjoyed a high reputation also as an architect, and designed the fine Renuccini palace at Florence, and many other palaces and public edifices there; he excelled also in some degree as a sculptor, and published a treatise on perspective.

CARDIGAN, a town of the Thracian Chersonese, at the head of the Melanian gulf, which was destroyed when he founded Lysistratus; was rebuilt in the Roman times, and is now the site of the ancient city a village now bears the name of Hexamili.

CARDIGAN, the county town of Glamorgan, on the river Taff, 170 m. from London; pop. in 1851, 18,351; returns one member to parliament. Until within the last 30 years it was a mere village; but the construction of a fine dock by the marquis of Bute, its proprietor, and the consequent opening of the collieries of South Wales, have converted it to an important commercial port. It is now the principal shipping port of the county.

Welsh steam coal, beside iron, and other local products. The entrances in 1852 consisted of 475 foreign vessels, tonnage 1,816; 1,816 coasting vessels, tonnage 1,711; clearances were 1,711 foreign vessels, tonnage 344,311; 6,212 coasting ves-

sels, tonnage 481,696. The greater part of the town is of course modern, and consists of good buildings, including 2 fine churches and several other places of worship. There are 5 schools, an infirmary hospital, and a union workhouse.

CARDIGAN, a seaport and borough of Wales, 289 m. from London; pop. in 1851, 8,876. The town carries on a small shipping trade along the coast, exporting agricultural produce and slates, and importing coal, limestone, and timber. The entrances of coasting vessels in 1852 were 587, tonnage 13,783; the clearances 50, tonnage 1,519. The foreign shipping is inconsiderable. There is an ancient castle in the town, the foundation of which is ascribed to Gilbert de Clare, toward the end of the 12th century.

CARDIGAN, JAMES THOMAS BRUDENELL, earl of, a British general of cavalry, born at Hambleton Oct. 16, 1797, was educated at Christ church, Oxford, and was gazetted May 6, 1824, as cornet in the 8th royal Irish hussars, under the courtesy title of Lord Brudenell. His family influence and wealth in England procured for him a rapid promotion, and in a few years he had attained the rank of major. At this time he became notorious for eloping with the wife of Major Johnston, whom he married on June 19, 1826, after the lady had obtained a divorce from her first husband. The union, however, proved unhappy, and eventually terminated in a separation. The death of this lady took place in London, July 15, 1858. Lord Brudenell was next, Dec. 8, 1830, made lieutenant-colonel of the 15th hussars. Lady Augusta Wathen, a lady of high connection, the wife of the major of that regiment, having obstinately refused to visit Lady Brudenell, Lord Brudenell subjected her husband to a series of persecutions which resulted in a court-martial, disclosing on his lordship's side a course of tyranny and espionage, which, notwithstanding his rank and influence, compelled his removal from the regiment and from active service. Indeed, it was only through the interference of William IV. moved by the entreaties of his father, that Lord Brudenell was restored and appointed lieutenant-colonel of the 11th light dragoons, then serving in India. This restoration to his rank was in 1834. Lord Brudenell was a member of the house of commons from the period of his coming of age in 1818, until Aug. 14, 1837, when on the death of his father, he became earl of Cardigan. After his regiment returned from India Lord Cardigan got himself into difficulties with the officers, who, one by one, had to sell out until the feeling of the regiment broke into mutiny in what was known as the "black bottle quarrel." This quarrel arose in 1840, while Lord Cardigan's regiment was stationed at Canterbury. One of his officers, Capt. Reynolds, having caused wine to be placed on the table in a "black bottle," Lord Cardigan accused him of degrading the mess to the level of a pot-house. This led to angry words: Capt. Reynolds was placed under arrest, demanded a court-martial, but this

privilege was withheld from him, and, as the public thought, unjustly. The excitement created by this affair and by his subsequent misunderstanding with another officer also of the name of Reynolds, had hardly subsided, when he fought a duel with Capt. Harvey Tuckett (Sept. 15, 1840), because this officer had censured his conduct in the "Morning Chronicle" newspaper. Capt. Tuckett was wounded, and Lord Cardigan tried before the house of lords, but, although acquitted, public opinion was against him. His reputation, however, as an accomplished cavalry officer, and the satisfaction which the duke of Wellington expressed in 1848, with the efficiency of the 11th hussars' regiment, which was under Lord Cardigan's charge, led to his promotion. On the outbreak of the Crimean war Lord Cardigan was raised to the rank of major-general, and appointed brigadier in command of the light cavalry brigade. This brigade constituted the celebrated "six hundred," whose charge at Balaklava will long be remembered as one of the bravest yet wildest feats, perhaps, ever told of in the history of war. On that occasion (Oct. 25, 1854), Lord Cardigan is said to have received from Lord Lucan, his brother-in-law, an order to capture certain guns from the Russians. A mile and a half had to be traversed, under fire, before the enemy could be met, and the Russian forces stood in formidable array in every direction. The enterprise seemed hopeless. Cardigan, however, led on the charge, and actually took the guns, his men cutting their way through the infantry support and through the cavalry, and then back again, under the play of the Russian batteries, but with fearfully diminished numbers, the survivors not exceeding 150. As the hero of this daring exploit, Lord Cardigan was received with great enthusiasm on his return to England, and appointed inspector-general of the cavalry. The charges, however, subsequently alleged by the Crimean commissioners, tended to reduce the high estimate placed upon his services.—In appearance Lord Cardigan is the beau-ideal of a light dragoon. Though 61, he carries his years with an arrogant air of juvenility. His frame, though slight, is well proportioned and knit, and he is gay and dauntless in bearing.

**CARDIGANSHIRE**, a county of South Wales; area, 693 sq. m., or 443,887 acres; pop. in 1851, 70,796. The county is mountainous, except in the N. E. near the sea, where it is flat. The rivers are small, and there are several small lakes. Slate is the prevailing geological character of the county. Veins of copper, lead, and zinc are found. Some domestic manufactures of woollen are carried on; oats, butter, and slates are exported. Remains of castles and religious houses are frequent, as are druidical remains and Roman encampments.

**CARDINAL** (It. *incardinare*, used synonymously with *intitolare*, to commission), originally, any clergyman bearing an official appointment in a principal church. By degrees, however, the

title became the exclusive principal clergy of the R as the natural counsellors required an influence and superior kind. Thus, in ecclesiastical senate was formed to assist the sovereign pontiff in the of the church; and the body was continually perfected ultimately fixed in its present Sixtus V. The dignity of cardinal in the Latin church, after elected by them alone. Caru rank of secular princes, being tors, and next after kings. Those worn by bishops, which those who are not in sacred ord use) are a purple mantle, a of sapphire set in gold. Every order he may have received, episcopal jurisdiction in his solemn benediction, and Those who are priests can give minor orders. They take prelates, even patriarchs, and have in general councils. The appointment rests exclusively with the pope. ber is never quite filled, and some reserved in *petto*, to be a death occurs or any other presents itself. It is customary to few cardinals recommended by Catholic sovereigns, who are cardinals. The constitutions of decrees of the council of Trent

he should be selected, as far as possible from all nations. The reasons of this are evident; for, as the pope exercises his authority over so many nationalities in different parts of the world, he has the advice of wise and learned men from civilized countries in order to give a truly catholic character to his administration.

**CARDINAL POINTS** of the compass, the four exactly N., E., S., and W.

**CARDINAL VIRTUES**, those moral virtues are regarded as being the basis of, and exist in greater or less degree in, all right men, so named from *cardo*, a hinge, as defining the fundamental point on which all turn. Of these the ancients reckoned 4, counting the 4 principal divisions of the circle which a hinge describes. These 4 were prudence, temperance, and fortitude.

**CARDOZO, JACOB N.**, an American journalist-political economist, born at Savannah, June 17, 1786. About 1794 his family removed to Charleston, S. C., where he received an English education, and from his 12th year was put to mechanical and mercantile pursuits. In 1816 he became editor of the "Southern Patriot" newspaper in Charleston, and in 1823, he became sole proprietor.

He long studied the principles of trade, commerce, and finance, and his purpose from the first was to render his journal especially an organ of free trade doctrines. Having a conviction that the commercial questions in the interests of the southern states were neglected, the commercial relations of the U. S. to the British West India islands, in their then depressed condition, engaged a large share of his attention. The removal of those restrictions was the object of constant solicitude with Mr. Cardozo's administration. To force a relaxation on the British government, congress in 1818 and 1820 adopted counteracting regulations. Whatever their effect on the British, they seemed to be oppressive on southern commerce.

In 1822 various seaport towns of the south, such as Norfolk and Baltimore, petitioned for their removal. The city of New York was so far inclined to second the movement that a large public meeting was held, and a memorial was drafted for its acceptance.

Mr. Cardozo regarded the case as an exception, and opposed the memorial. He was against unlimited freedom of intercourse where reciprocity was denied, and at a town meeting of the citizens the memorial was rejected, leaving the whole matter in the hands of congress and the executive. The result which was aimed at by countervailing resolutions of congress was not seen in the partial removal of the restrictions. When this was done, President Monroe opened the ports of the United States to the vessels of the British West India.

Cardozo took an active part in the movement, in 1823, of the Charleston chamber of commerce. The tariff of 1824 met with

little or no united opposition from the south. When, in 1827, an increase of protection was agitated, it resulted in the act of 1828. Mr. C. brought the subject before the chamber, and was one of a committee appointed to draft a memorial to congress, which was unanimously adopted by the citizens of Charleston in a public meeting. The arguments on the subject, however new, rapidly made their way into the public mind of that state, and constituted the chief political capital of the press and parties. The agitation ripened into nullification, the controversies upon which began in 1828. Mr. Cardozo continued his opposition to the protective tariff, still maintained his free trade argument, but declined to adopt the extreme practical results to which nullification was expected to conduct. The advocates of nullification succeeded in the state, but Mr. C. forfeited none of the public esteem in consequence of his course. He continued to conduct the "Southern Patriot," keeping it steadily the exponent of the commercial principles of which he had been so long the advocate, until 1845, when he sold the paper, and soon after, in the same year, established the "Evening News," another daily newspaper, with which he has ever since been associated as commercial editor. His reputation as a political economist has become fixed in the esteem of the southern people, though few know how extensively he has written on all the subjects we have indicated. He has contributed to the "Southern Quarterly Review" and other periodicals, and in 1826 he published "Notes on Political Economy," 1 vol. 8vo.

**CARDROSS**, a Scotch village, on the Clyde, in the county of Dumbarton, pop. 4,400, with bleacheries and cotton manufactories; celebrated for its Castle hill, the name given to the site where once stood the castle which Robert Bruce built, and where he died, June 7, 1329.

**CARDS**, in cloth manufacture, are combs of a peculiar construction, which serve to disengage the fibres of an entangled mass and lay them parallel. Every fibre on the card is doubled up, and they are afterward extended by an operation called drawing and doubling. Cards are made by inserting in a piece of leather fine wires projecting about  $\frac{1}{4}$  inch from the leather, and all slightly bent the same way. These small hooks are prevented from turning by being made in pairs. Two of them are made of a piece of wire bent like the 8 sides of a square; this is inserted through 2 holes in the leather, and the 2 projecting ends are bent in the same direction. The leather, bristling with hooks, is attached to a flat or cylindrical surface. A card is an instrument in which 2 such surfaces are opposed, and made to move at a very small distance from each other; the cotton or wool to be disentangled is placed between them. The cards opposed to each other are placed in different positions according to the result to be obtained. At first the hooks are placed in op-

posite directions, so that at each stroke some of the fibres of the tuft are hooked on one card and some on the other; this is called the tearing position. After all the fibres are hooked on, one of the cards is reversed, and at the next stroke the card which moves in the direction pointed out by its own hooks strips from the other all the fibres; this is called the stripping position. Flat cards have been used by hand in the manner just described. Cylinder cards and the carding machine were invented in the 18th century by Lewis Paul of Northampton, England, and were much improved by Sir Richard Arkwright. The cotton or wool is in general passed through 2 carding machines before it is ready for the next operation; these are called the breaker and the finisher, and the only difference between them is that the teeth of the last machine are finer than those of the other. The principal parts of the most improved carding machine of our time are: 1. A main drum, 35 inches diameter, with a circumference velocity of 20 feet per second; it is covered with strips of cards parallel to the axis, laid on at a small distance from each other, and moves in the direction pointed out by the teeth. 2. Top cards, or narrow, flat cards, which are stationary above the main drum, and parallel to its axis; they rest by their ends on the frame of the machine, are tangential to the drum, and their distance from it is nicely regulated by screws. The teeth of the top cards and of the drum are in the tearing position. 3. Two feed-rollers,  $1\frac{1}{2}$  inch diameter, velocity  $2\frac{1}{2}$  inches per minute; they are on a level with the axis of the drum, and on the side which moves toward the top cards. 4. A large runner or cylinder,  $6\frac{1}{2}$  inches diameter, 14 feet velocity per second; it is tangential and parallel to the drum, and is situated between the feed-rollers and the top cards; the teeth are in the tearing position. The drum moving from right to left, the large runner moves from left to right. 5. A small runner,  $3\frac{1}{2}$  inches diameter, 7 feet velocity; it is tangential at the same time to the drum and to the large runner, and stands between this and the feed-rollers; it moves from left to right, strips the large runner at a velocity of  $14+7=21$  feet, and is stripped by the drum at a velocity of  $20-7=13$  feet. 6. A doffer cylinder, 14 inches diameter, 27 feet velocity; it is parallel to the drum, and turns from left to right; its teeth are in the tearing position; it stands in front of the top cards. 7. A doffer knife, like an ordinary comb; it has an up and down motion in contact with the doffer, which it strips of all its fibres, thus forming what is called a fleece. 8. The funnel through which the fleece passes, and where it is contracted into a ribbon. 9. Two pairs of drawing rollers, and 2 delivery rollers. The width of the machine, or length of the various cylinders, is 8 feet. The strips of cards on the runners and doffer are placed spirally. Sometimes small card cylinders, called squirrels, are substituted for the top cards.

This machine operates as follows or cotton to be carded, after being in the shape of a sheet in another engaged between the feed-rollers, are taken off by the drum and card large runner, which takes off the and is stripped of them by the doffer which returns them to the drum. carries them anew to the large runner are hooked more firmly and move the top cards; some of them remain others are completely extended and doffer, which takes off a portion of the are stripped from it by the doffer. form the fleece; the others are carried again to the runners and top cards; passage some are taken off. From the top cards and cylinders are the fibres accumulated in their teeth. 7 cards 2 lbs. 5 oz. of cotton per hour. MACHINE FOR MAKING CARDS was that of Amos Whittemore, of Cambridge which he took a patent in 1787. A patent was issued in 1811 to J. C. A fillet of leather is prepared of equal throughout by drawing it between a and a scraper, which takes off all. One end of the fillet is then placed between feed-cylinders, and is guided laterally. These are acted upon at intervals, as they move they carry the fillet a distance between 2 hooks. When necessary to place the hooks in oblique position described is combined with a new feed-rollers. After each motion of leather, a fork brought down at the pierces 2 holes in the leather; a piece drawn steel wire is fed in; a small steel descending upon it holds it; wire is cut off; 2 sliding pieces of it up against the sides of the blocks points are pressed into the holes in the blocks and other parts spoke out of the way, and other parts forward to drive the staple in and to required angle. All these operations effected by means of rotary cams the ends of levers or of rods, some periphery, some by their sides, as is machines for manufacturing small objects require to be submitted to numerous complex motions.—Nearly 100 patents have been granted by the United States government in cards, carding machines making. About 5 new ones are every year.

**CARDS, MANUFACTURE OF.** 1 address cards are prepared from made by pasting a sheet of cartridge between 2 sheets of white or colored for ornamented backs, sheets may with the intended design. Cardboard thickness may have 2 or more sheets of cartridge paper interposed. As ordinary the first process, called mingling, is a sheet of cartridge paper between

sheets in a ream of white demy paper. The pile thus made is called a head. Placed on a table at the left hand of the paster, he draws down the top sheet, and brushes it over with paste; then the cartridge paper, drawn down on the pasted surface, is treated in the same way, and its surface is immediately covered with 2 sheets drawn down at once upon it. The upper one is pasted for the next cartridge paper, and so on till the head is again made up. It is then subjected to the action of a powerful hydraulic press, by which the water is expelled from the sheets. Removed from this, each outside pair is successively taken off, one board at each end of a copper wire, and suspended on lines 24 hours in a heated room to dry. The boards are then passed between stiff cylinder brushes, by which they are well rubbed and partially polished. They may next be varnished on the side to be the backs, thus making them water-proof and less likely to be soiled. They are then rolled between a warm iron and a paper roller, as in the process of calendering, next between 2 polished iron rollers, next with smooth sheets of copper interposed between the cardboards, and finally they are subjected to a pressure of 800 tons. The boards are thus made straight and even, and receive a finely polished glazed surface. If not intended for playing cards, they may now be cut into the required sizes of address cards. To be enamelled, they receive an application of china white, or silver white, (a very pure variety of white lead,) which is first mixed with water containing some fine size, made from parchment-cuttings boiled down. This application, being smoothed over with a badger's hair brush, is first dried, then rubbed over with flannel dipped in powdered talc, and finally polished with a close-set brush.—The old way of painting playing cards was by the use of stencil plates, with openings corresponding to the spots, each plate comprising many cards, so as to cover a cardboard. Through these openings the color was introduced with a brush. The court or face cards required a stencil for each color, one being applied and then another, the open spaces in each being where the color used with it belonged. The operation somewhat resembles the printing of colors on cloth. (See CALICO.) A cardboard, when thus painted, was cut up into its separate cards. The English manufacturers receive the print of the ace of spades from the stamp office, this being the duty card, costing the manufacturers 1s. sterling. But if the cards are for exportation, no duty is required, and the duty card in this case bears a printed notice, forbidding its use in Great Britain and Ireland, under a penalty of £20. Printing has succeeded to the use of the stencil, and the process in use for applying different colors, is by blocks, essentially the same as those of the calico printer. The colors are carefully prepared of the best materials—French lampblack for the black, and Chinese vermilion for the red—each ground in oil.—Of the 4 prin-

cipal card manufactories in the United States, 1 is in Philadelphia and 8 are in New York. Mr. Levi, in the latter city, has the largest establishment. He employs 100 hands, has a 25 horse-power steam engine, and all together has \$40,000 worth of machinery. Every week 250 gross of packs are turned out of this factory. The largest demand for cards is in the southwest, each pack is used only once or twice, and then thrown away; a great number are used once on board of our western steamboats, and then thrown away. See CARD PLAYING.

CARDUCCIO, BARTOLOMMEO, an Italian painter, born at Florence about 1560, died in Madrid in 1610. He painted the frescoes in the palace cloisters and the ceiling of the library at the Escorial. His greatest work is the "Descent from the Cross," in the church of San Felipe, in Madrid. He also wrote a book on painting, published at Madrid, 1638.

CARDUCHI, ancient warlike tribes, the ancestors of the present Koords, who inhabited the mountainous regions between Mesopotamia and modern Persia, now named Koordistan. They were famous for their skill in archery, and baffled all the attempts of Persian monarchs to subdue them. The retreat of the 10,000 Greeks, after the battle of Cunaxa, lay through the country of the Carduchi, and was harassed by constant attacks from the natives. Xenophon gives a complete account of their habits and modes of life in his history of this retreat.

CAREER, in horsemanship, both the ground that is proper for the manège and a course, and the race of a horse which does not go beyond 200 paces. The original use of this exercise was for purposes of arms, in the tilt yard. A horse, to be perfect in his career, should spring at once to speed, increase his momentum at every stride, and be at his utmost at the moment of reaching the extremity of the distance.—In arms, career signifies the course which is run, in the tilt or tourney, by two knights, from the place at which they sit on their horses, facing one another, with their visors closed, their shields hanging about their necks, and their lances in rest, awaiting the signal given by the words *Laissez aller*, "Let them go," and the blast of trumpets, to that where they encounter in the middle of the lists. The great merit of the career, in the horse, is to spring at once, at the sound of the trumpet, before feeling the spur, to his full speed, and to increase or maintain the impetus to the very moment of the shock; for, in exact proportion to his delivering his maximum of weight and speed against the horse opposed to him, or relaxing it, and meeting his adversary panting and blown, will be the effect of the charge. The beauty of the career, in the rider, is to deliver the point of the lance horizontally, or, as it is technically called, fairly, against the visor or shield of his antagonist, so as either to unhorse him, or to break the spear to splinters, at the same time sitting so

firmly himself as to resist the blow of the opponent's lance, and with so good a hand as to prevent the charger he rides from swerving or going down in the shock. To unhorse the adversary, himself unshaken in his seat, is the crowning glory of the career. To break the lance crosswise on his person, failing to strike him with the point, or to strike him with the point on the leg, thigh, right arm, or anywhere except on the shield or crest, is the greatest fault. To be unhorsed, or to lose a stirrup, or to let fall the lance, was to lose the career.

CARÊME, LOUIS ANTOINE, a French cook, born June 8, 1784, at Paris, died Jan. 12, 1833. His family was so poor, that when a mere boy, he was sent out by his father to try his luck in the great metropolis. He found admittance to a low cook-shop, where he worked for his living. At 16 he became assistant cook at a fashionable eating-house, and, through his natural taste, made rapid progress in his profession, which he studied scientifically. In 1804 he had reached such a degree of proficiency, that he entered Prince Talleyrand's kitchen, where he accomplished wonders which gained him an unparalleled reputation. In 1815 he consented to serve the prince regent at London, but, unable to reconcile himself to the climate of England, he left the prince at the end of 2 years. Russia, whither he was called by Emperor Alexander, was equally uncongenial; neither could he remain permanently in Vienna, where he prepared several banquets for the emperor. He also evinced his talents at the congresses of Aix la Chapelle, Laybach, and Verona, remained some time at the court of Würtemberg, and finally returned to France, where his services were secured by Baron James Rothschild. Carême was indeed an artist in his line, always eager for progress and improvement; he peculiarly excelled in pastry, and the general arrangement of serving the table. Most of his earnings were devoted to culinary researches, and to publications expounding the mysteries of a calling which he raised to the dignity of an art. His most important book is *Le pâtissier pittoresque*, illustrated by 128 plates, but the most useful are *Le cuisinier*, and *Le pâtissier Parisien*. His special erudition is evinced in *Le maître d'hôtel Français*, a comparison between ancient and modern cooking.

CARENAC, a French commune and village, in the department of Lot, 85 m. N. N. E. from Cahors; pop. 1,122. It has an ancient abbey, of which Fénelon was the head when he was made archbishop of Cambrai, and a tower in which he composed a portion of his works. Freestone is wrought in its environs.

CAREW, THOMAS, an English poet, born in Gloucestershire about 1589, died 1639. He studied at Oxford, and afterward became gentleman of the privy chamber to Charles I. He enjoyed the friendship of Ben Jonson and other poets of the day, and at court he was much esteemed for the vivacity of his wit and the elegance of his manners. He wrote sonnets and

amorous poetry, and a masque set to music by Henry Lawes, called *Cæsar Britannicus*. It was performed by the king and nobles, at Whitehall, in 1633, on Shrove Tuesday.

CAREY, ALICE, an American authoress, born in 1822 at Mount Healthy, near Cincinnati. She had but the slight advantages of education furnished by an occasional attendance at a country school. She first attracted attention by some sketches of rural life, published in the "National Era," under the signature of Patty Lea, and has since been a frequent contributor to periodicals. In 1850 a volume of poems, the joint work of herself and her sister Phoebe, appeared in Philadelphia. This was followed in 1851 by her romantic poem of "Hualco," by "Lyra and other Poems" the next year, and by a new collection of poems in 1855. During the same period she has published, under the title of "Clever-nook," 8 series of sketches of western life and scenery, and also 8 novels, the first of which, entitled "Hagar, a Story of To-day," appeared in 1858, and was quickly succeeded by "Married, not Mated," and "Hollywood."—PAMELA, an American poetess, the younger sister of the preceding, born near Cincinnati, in Ohio. She has contributed frequently to periodicals, and also published in 1854 a volume of "Poems and Parodies."

CAREY, GEORGE SAVILLE, an English dramatic poet, born in 1745, died in 1807. He was first intended for a printer, but became an actor, and spent 40 years in composing and singing popular and patriotic songs. He was the author of certain farces by which he procured a precarious subsistence.

CAREY, HENRY, a poet and musician, was a natural son of George Saville, marquis of Halifax. "God save the King" has been attributed to him, and the ballad of "Sally in our Alley" is his. The various talents of this gentleman did not procure him a comfortable subsistence, and, in a fit of desperation, he killed himself in 1748.

CAREY, HENRY CHARLES, an American political economist, a son of Mathew Carey, born in Philadelphia, Dec. 15, 1798, was educated as a bookseller, entering his father's store at the early age of 8, and remained there, mingling his elementary studies in literature with business, until his majority, in 1814, when he became a partner in the firm. This association continued till his father retired in 1821. He then became the leading partner in the firm of Carey and Lea, and subsequently in that of Carey, Lea, and Carey, in their time the largest publishing house in the country. In 1824 he established the system of trade sales, now the great medium of exchange between American booksellers. In 1835, after an eminently successful career, he withdrew from this business, to employ his large capital in industrial enterprises. From an early period a careful observer of public affairs, and especially of whatever concerned the industrial prosperity and progress of the country, his interest in subjects of political

economy now found a larger field in which his own practical experience and theoretic studies could mutually guide each other. Originally a zealous partisan of the idea that the principles of absolute free trade ought to be immediately and unconditionally applied in the foreign commerce of the United States, he presently came to the conviction that real free trade with foreign countries was impossible in the present state of American industry, and that a period of protection, by means of imposts on the importation of foreign manufactures, must first be gone through with. In this view, free trade is the ideal toward which we ought to tend, and protection the indispensable means of arriving at it. Thus Mr. Carey is both a free trader and a protectionist. His doctrine on this subject is, however, but incidental to his general system of political economy, or, as he prefers to call it in his latest publication, social science. His views will be more fully explained in the article **POLITICAL ECONOMY**; their central principles are, briefly, that in the weakness of savage isolation man is subject to nature, and that his moral and social progress are dependent on his ing nature to himself; that the land, unassisted in itself, gains all its value from human labor; that the primitive man, without land and without science, of necessity begins cultivation upon the light, salubrious, and fertile soils of sandy elevations, and gradually passes to the subjugation of more fertile and cultivated regions; that the real interests of classes and individuals are essentially harmonious; that there is, in the normal condition of things, a constant tendency to increase in the wages of labor, and to diminution in the rate, though to a decrease in the aggregate, of the profits of capital; and that the well-being and advancement of society correspond to the degrees of association and liberty which exist in it. His theory is thus, in some important respects, opposed to the ideas prevailing among the majority of European economists, Bastiat alone, of all prominent European writers on the subject, having defended the theory of general harmony against that of general antagonism.—The first book published by Mr. Carey was his "Essay on the Rate of Wages, with an Examination of the Causes of the Difference of the Condition of the Laboring Population throughout the World" (1835). This work was reproduced and expanded in "The Principles of Political Economy," 3 vols. 8vo (1837, '38, and '40). He next published "The Credit System in France, Great Britain, and the United States" (1838); "Answers to the Questions, What Constitutes Currency? What are the Causes of its Unsteadiness? and What is the Remedy?" a pamphlet (1840); "The Condition of the Present, and the Future," 8vo, pp. 100 (1848); "The Harmony of Interests" (1850); "The Slave Trade, Domestic and Foreign: Why it Exists, and How it may be Extinguished;" "Letters on International Copyright" (1853); "Letters to the President on the Foreign and Domestic Policy of

the Union, and its Effects, as exhibited in the Condition of the People and the States" (1858). For several years Mr. Carey also contributed the leading papers in "The Plough, the Loom, and the Anvil," a monthly periodical, some of which were afterward collected in his "Harmony of Interests." Through the whole period of his industrious authorship of books, he has also written much in some of the principal newspapers of the country, on subjects connected with his special study. He has now in course of publication a work entitled "Principles of Social Science," 3 vols. 8vo, of which the 1st and 2d were issued in 1858, and the 3d is to follow early in 1859. The principal of these works have been translated and published in Italian and Swedish.

CAREY, MATHEW, an American publisher and author, born in Dublin, Ireland, Jan. 28, 1760, died in Philadelphia Sept. 16, 1839. His father was a government contractor, who, having amassed a handsome fortune, bestowed upon his 5 sons a liberal education. When Mathew was 15 years of age, being allowed by his father to choose from a list of 25 trades his future occupation, he selected the business of printer and bookseller; and 2 years later began his career as an author by publishing a pamphlet on duelling, followed soon after by an address to the Irish Catholics on their oppression by the penal code, which was so inflammatory that its publication was suppressed, and the author avoided prosecution only by a flight to Paris. He remained there a year, during which he became acquainted with Dr. Franklin, then representing the United States at the court of Versailles, who gave him employment in his private printing office at Passy. After his return to Ireland he edited for a short time the "Freeman's Journal," and in 1788 established a new paper called the "Volunteer's Journal," which soon obtained a very extensive circulation consequent upon its bold and uncompromising advocacy of measures of the opposition, which led soon after to the recognition by Great Britain of the legislative independence of Ireland. One of its attacks on the parliament and ministry was followed in 1784 by an indictment for libel. Carey was arraigned before the house of commons, and by sentence of that body committed to Newgate, where he remained till the adjournment of parliament. Other prosecutions, however, were still hanging over him, and to avoid them he took the advice of his friends and embarked for Philadelphia, where he arrived Nov. 15, 1784. The account of his trial had preceded him, and Lafayette, who had formerly known him in Paris, now assisted him here. He was enabled to start the "Pennsylvania Herald" newspaper in Philadelphia, in about 2 months after his arrival there. This journal was the first in America to give accurate reports of legislative debates, Carey being himself his own reporter. Its spirited conduct otherwise gave it a high reputation, but also involved its editor in a personal controversy. The result was that Carey fought a duel with

Colonel Osborne, the editor of a rival journal, and received an injury which confined him to his house for more than 16 months. After this he attempted with several partners the publication of the "American Museum," a magazine continued with excellent ability, but little success, for 6 years. In 1791 he married, and began business as a bookseller, on a very humble scale. During the prevalence of the yellow fever, 2 years later, he was a member of the committee of health, and active in his study of the disease and attentions to the sick; and the results of his extensive observation were collected and published in his "History of the Yellow Fever of 1793," which passed through 4 editions. In 1796 he was one of a few citizens who united under the direction of Bishop White in the formation of the first American Sunday-school society. In 1802 he published an edition in quarto of the Bible, and stereotyping not then having come into use, the entire volume was kept in type to supply the demand for reimpressions. At his suggestion also the booksellers and printers of the Union met in New York, to form an association similar to the book fairs of Germany. The plan did not succeed, but it was the germ of the subsequent trade sales. He engaged warmly in the discussions concerning the U. S. bank, writing articles for newspapers, publishing pamphlets of his own composition, and distributing them freely at his own expense. In 1814 appeared his "Olive Branch, or Faults on both sides, Federal and Democratic," designed to harmonize the 2 furiously antagonistic parties of the country, pending the war with Great Britain. It passed through 10 editions, and is yet regarded as high authority in regard to the political history of that period. In 1818 he published his *Vindiciae Hibernicae*, an examination and refutation of the charges against his countrymen, made by British writers, in reference to the shocking butcheries alleged to have been committed by them in the rebellion of 1641. From this time forward he devoted himself almost exclusively to politico-commercial pursuits, publishing in 1820 the "New Olive Branch," in which he endeavored to show how harmonious were the real interests of the various portions of society; and in 1822, "Essays on Political Economy." This, in turn, was followed by a series of tracts, extending to more than 2,000 pages. The object of all these publications was that of demonstrating the necessity for adopting the protective system, as the only means of promoting the real interests of all classes of the community, whether farmers, traders, or manufacturers. Enthusiastic in the prosecution of any work in which he allowed himself to become engaged, he devoted to the examination of this question all the powers of a vigorous mind, and thus contributed largely toward bringing about the change of public policy manifested in the passage of the tariff acts of 1824 and 1828. Highly public-spirited, he was active in the promotion of all the public works of his city and his state, from the com-

menement of his American career down to the inauguration of the system of internal improvements, which led to the construction of the Pennsylvania canal. Eminently philanthropic, he was ever active in the promotion of education, and in the formation of associations having for their object the relief of those who were unable to help themselves. Few men have lived more generally respected; few have died more generally regretted by the community in which they had lived and moved.

CAREY, WILLIAM, a Baptist missionary and oriental scholar, born in Paulerspury, Northamptonshire, England, in 1761, died at Serampore, June 9, 1834. He was the founder, in connection with other ministers, of the first Baptist missionary society. In 1793 he devoted himself personally to the missionary work, and embarked, accompanied by his wife and sister, for India. On his arrival, he fixed the scene of his labors at Mudnabatty, but was not permitted by the Indian government to make a permanent establishment there. He next removed to the Danish settlement of Serampore, where he established that large and successful missionary post of his denomination, which has been the theatre not only of his own labors and death, but of the toils of Ward and Marshman, that distinguished oriental scholar, and English translator of Confucius. Carey became an unremitting student of the oriental languages, and lived to see 40 different oriental dialects become the channels of transmission for Christianity to as many tribes. In addition to these labors, he taught in the college of Fort William the Bengalee, Sanscrit, and Mahratta languages, and furnished to the Asiatic society, of which he was a member, many valuable papers on the natural history and botany of India. He brought the Scriptures within the reach of many millions of human beings.

CAREZ, JOSEPH, an eminent French printer, born in 1753 at Toul, died in 1801. He materially contributed to the progress of the art, being considered one of the inventors of the stereotype method. He was a member of the legislative assembly, and subsequently distinguished himself among the volunteers of 1793.

CARGILL, DONALD, a Scotch Presbyterian and Covenanter, and a leader of the Cameronians in and after the Sanquhar declaration, born in the parish of Rattray, Perthshire, about A. D. 1610, executed in Edinburgh, July 27, 1681. He was educated at Aberdeen, entered the Scotch church, and was minister of Barony parish of Glasgow, some time after the division among the clergy in 1650, until the restoration of the English church by Charles II. in 1661, when he refused to accept collation from the archbishop, and to celebrate the king's birthday. He was banished beyond the Tay, but paid no attention to the act. In 1666 he was called before the council, and peremptorily commanded to depart. When indulgence was proclaimed to the Presbyterian ministers, he refused to accept it, and made a stand with

Bothwell Bridge against the royal though severely wounded in that conflict, was compelled for a time to flee to Holland,

in Scotland in 1680, and with a zealous enthusiast named Hall, lurked on Queen's Ferry for several months, eluding the notice of the authorities, until June 8, when they were arrested, and Hall killed in the person of Hall was found the paper known in the ecclesiastical history as the "Queen's Ferry Covenant." On June 22, with Cameron and others, he made a Sanquhar declaration. In the September following, after he had preached to a congregation in the Torwood, between Falkirk and Glasgow, from "Is Christ divided," &c., he was excommunicated against the king and state dignitaries, because they had denied the supremacy of the pure church of Scotland.

He was now excommunicated, and a noose was put on his head. In May, 1681, he was executed at Covington, Lanarkshire, and his body was taken to Lanark on horseback with his feet sticking out of the horse's belly. From Lanark he was taken to Glasgow, and thence to Edinburgh, where he was hanged and beheaded for high treason.

**CARGO** (Welsh *carg*, a load), the goods, wares, or other effects which constitute the cargo of a ship. The lading within the hold is called the inboard cargo, in distinction from the cargo may carried on deck. The person employed by merchants to take charge of a cargo is called a supercargo. *Cargo* is also a Spanish and Italian word.

**CHARLEVOIX**, ÉTIENNE DE, a Jesuit missionary who first visited these tribes in 1668, obtained the complete mastery of their languages, and was respected by the savages both as a saint and a man of genius. The date of his death is unknown, but he was still laboring with untiring activity, though with little success, when Charlevoix left Canada.

**CARIA**, an ancient country situated in the south-western part of Asia Minor, separated from Lydia by the mountains Messogis. It was intersected by low mountains, which ran far out into the sea, and formed several spacious bays. Its chief river was the Maeander. The valleys between its mountains were fertile, producing corn, grapes, oil, &c. The Carians, according to Herodotus, were the aboriginal inhabitants of the region, a branch of the Pelasgic race, originally settled in the islands of the Ægean. When the Persians formed a navy, and subdued the islands, he transplanted them to Asia Minor. After times Greek colonies repelled them from their coasts, and built cities on the coast; while the Lydian kings, Croesus, subdued the inland country. After the overthrow of the Lydian monarchy, the Carians became subject to the Persians, and when the sceptre of the Persian was passed under the sway of Alexan-

der. Later their territory was successively annexed to the kingdom of Egypt and the kingdom of Syria. After the Romans had vanquished Antiochus, they gave Caria to the Rhodians and Attalus in reward of their fidelity and services as allies; and on the conclusion of the Mithridatic war, they ultimately annexed it to their proconsular province of Asia. The considerable cities of the country—Halicarnassus, Cnidus, and Miletus—were the work of Greeks, not of Carians. The Carians had the same religion as the Lydians and Mysians. Their language was of the Lydian stock, and accounted barbarous by the Greeks of historic times.

**CARIACO**, the largest of the Grenadine group of the Windward islands, being about 21 m. in circumference, situated in lat. 12° 30' N., long. 62° 30' W., between St. Vincent and Grenada, possessing 2 bays on the N. side, and a town named Hillsborough.

**CARIBBEAN SEA**, that portion of the Atlantic lying between Cuba, St. Domingo, and Porto Rico on the N., Venezuela and New Granada on the S., the Lesser Antilles on the E., and Guatemala on the W., and communicating with the gulf of Mexico through a channel about 120 m. wide, extending from the W. point of Cuba to the E. point of Yucatan.

**CARIBBEE ISLANDS**. See **ANTILLES**.

**CARIBOU** (*tarandus rangifer*, or *cervus tarandus*), the American reindeer. Of this animal several varieties have lately been recognized. Concerning the reindeer Dr. J. E. Gray observes that it varies exceedingly in size. In the British museum there are specimens varying from 3 feet 5 inches to 4 feet 2 inches at the withers; but that distinction is very trifling in comparison to what really exists. Richardson observes that there are 2 well-marked permanent varieties of caribou that inhabit the fur countries; one of them, the woodland caribou, confined to the woody and more southern district, and the other, the barren ground caribou, retiring to the woods only in the winter, but passing the summer on the coast of the Arctic ocean, or on the barren grounds so often mentioned in his work. The large Siberian variety is ridden on by the Tungusians, and they also use them for draught, as the Laplanders do the smaller variety. There is a large variety in Newfoundland, and throughout the British provinces of Nova Scotia and New Brunswick, which have extraordinarily large and heavy horns. It is observed by Dr. Gray, quoted above, that the horns of the Newfoundland variety, some of which are preserved in the British museum, greatly resemble those of the Siberian animal; but Pallas observes that the American species differ from the former in the structure of the hoof, and are absolutely American animals. The tame reindeer of the Laplanders is, according to Hoffberg, at the end of his back an ell and a half high, and his length, from horns to tail, is 2 ells, while from the navel to the backbone he measures  $\frac{3}{4}$  of an ell. If these ells are to be understood

as measures of an English yard, the estimate is immensely exaggerated, since the animals in the English zoological institution, and elsewhere exhibited, do not approach that size, which is fully equal to that of the great American deer, called elk in the west, the wapiti of the Indians; while the true reindeer of domestication does not exceed the English red deer, if it equals it, in size. On casting his coat, the hair of the reindeer is brownish yellow, but, as the dog days approach, it becomes whiter, until it is at last almost entirely white; this, it must be observed, is spoken of the domesticated animal. Round the eye the color is always black. The longest hair is under the neck. The mouth, tail, and parts near the latter, are white, and the feet, at the insertion of the hoof, are surrounded with a white ring. The hair of the body is so thick that the skin cannot be seen when it is put aside, for it stands erect, as in other animals of the same genus, but is much thicker. When the hair is cast, it does not come away with the root, but breaks at the base. The horns are cylindrical, with a short branch behind, compressed at the top, and palmated with many segments, beginning to curve back in the middle, and are an ell and a quarter long. A single branch sometimes, but seldom two, springs from each horn in front, very near the base, frequently equalling the length of the head, compressed at the top and branched. The distance between the tips equals the length. This description, both of the horns and colors, differs in every respect from the wild caribou of North America. The color of that animal is, in the summer, a rich, glossy, reddish brown, becoming more grizzly, especially about the head, neck, and belly, toward the winter; but it never becomes any thing approaching to white. The antlers of the woodland caribou, on rising from the head, curve backward and then forward in a segment of, perhaps, the 6th of a circle for about half their length, or somewhat less; then curve backward again, and again forward, making in the upper sweep nearly a semicircle. They have no backward branch or spur whatever, except one short point close to the tip. The main branch of the antlers is cylindrical, much smoother than those of the red deer or wapiti, and at the upper extremity has 2, 3, or 4, but seldom more than 2, sharp cylindrical spikes. That, however, which constitutes the main difference between the antlers of this animal and of the tame reindeer, or, indeed, of any other of the deer tribe, is this: that while on the upper extremities of the horns are rounded spikes, the lower branches are broad palmated surfaces. The lower of these, or brow antler, which is the principal defensive weapon of the animal, curves downward over the eyes, and is several inches in breadth, with many sharp spurs, or points, round the lower border. The second, or superior process, which shoots horizontally forward from the point where the two curvatures of the main antler meet, is longer than

the lower or brow antler, and looks as if it were more so than it really is, from the direct line in which it projects, instead of being deflected downward. The forward points of the brow antler, the sur-antler, and the upper tips or extremities of the whole, are as nearly as possible in a right line. The measurement of a medium-sized set of antlers, from Newfoundland, in the possession of the writer, is as follows: extreme width from tip to tip, 1 foot 4½ inches; length of the exterior curvature, from root to tip, 2 feet 3½ inches; direct height 23 inches; girth at the root of the antler 5½ inches; at the insertion of the upper prong 4 inches; length of palmated brow antler 11 inches, breadth 8 inches, processes 7 in number; length of the sur-antler 12 inches, breadth 8 inches, processes 8 in number, very strong and sharp. The prongs of the upper extremity are irregular, one antler having 3, the other 3 points. The caribou has a short tail, like the scut of a hare or rabbit, and entirely different from the long flag of the red deer or wapiti. The hoofs have an immense spread, owing to the extension of the cleft of the hoof through the corset, and far up the pastern of the animal, which gives it, when running over soft snow, or, what is worse, over a crusted surface, a support almost equal to that of a snow-shoe. The average weight of the woodland caribou is from 250 to 300 lbs., that of the barren ground caribou from 90 to 180 lbs.; those of Spitzbergen and Melville island do not exceed 125 lbs. The reindeer of Norway and Sweden are diminutive as compared with those of Finland and Lapland, which again yield to those of Spitzbergen, which last are not half the size of the woodland caribou of North America. It will probably appear, on further investigation, that there are at least half a dozen distinct varieties of this curious animal; as it is wholly anomalous that the domesticated species should have fallen off in size, the universal tendency of domestication and culture being to increase the size of all animals, and to produce diversity or variegation of color.—The reindeer of Lapland, in domestication, feeds wholly on a species of lichen, peculiar to the country he inhabits, for which he roots under the snow with his nose, after the fashion of swine. He will eat no dried fodder, unless it be, perhaps, the river horsetail, *equisetum fluviatile*. To the Laplander the reindeer is invaluable, being in fact his ox, his sheep, and his horse, in one animal. He is too valuable to kill, in general, although his meat is delicious; but the milk of the herd is the principal support of the owner and his family; while, as an animal of draught, its speed, endurance, and its particular adaptation to travelling on snow, render it the most valuable, or one might say indispensable, of creatures to men dwelling in the high frozen latitudes. The ordinary weight drawn by this brave little animal is 240 lbs., but he can travel with 300. Their speed would be incredible if it were not attested beyond the possibility of doubt. In

of 8 in light sledges, started by Pictet in when he went north to observe the transit of Venus, the 1st performed 8,089 feet  $8\frac{26}{100}$  inches in 2 minutes, being at the rate of nearly 1 mile in the hour; the 2d went over the ground in 3 minutes, and the 3d in 3 minutes and 26 seconds. The endurance, however, of a reindeer exceeds its speed, which has been easily outdone by the American trotting horse. It is not unusual, it is credibly recorded, for the deer to do journeys of 150 miles in 19 hours;

the portrait of one is preserved in the palace of Drotingholm, in Sweden, which performed

its important despatches, and dropped dead when the astonishing feat was accomplished. To the natives of North America, the reindeer is known only as an animal of chase, but it is the most important one; there is hardly a part of the animal which is not made available to some useful purpose. Clothing made of the skin is, according to Dr. Richardson, so impervious to cold, that, with the addition of a blanket

of the same material, any one so clothed may move on the snow with safety, in the most intense cold of an arctic winter's night. The reindeer, when in high condition, has several inches of fat on the haunches (a state of things very unusual in the American deer, *cervus Virginianus*, which, although a highly flavored meat, is usually lean and dry), and is said to equal the venison of the best fallow deer of the English parks. The geographical range of the caribou is over all the northern parts of Europe, Africa, and America; and it is observed by Mr. Bennet, that they are spread abundantly over all the habitable parts of the arctic regions, and neighboring countries, extending in the new continent to a much lower latitude than the old, and passing still further south on all the principal mountain chains. In America the northern limit of the reindeer appears to be about the parallel of Quebec, across the whole continent; but the animal is most abundant between  $63^{\circ}$  and  $66^{\circ}$  N. lat. It has been found, that this is probably accidental, in that singular mountain region known as the Adirondac Highlands, in the north-eastern part of the state of New York, within 50 miles of Albany.

CARIBS, or CARIBBEES, an aboriginal tribe of South America, originally in possession of all the West India islands between Porto Rico and the gulf of Paria. They were compelled to leave the islands after the arrival of the Europeans. A small number of them are now found in Trinidad, Dominica, and St. Vincent. The race is also found on the shores of Central America and on the South American continent, along the lower Orinoco and the Amazon.

CARICA, a remarkable tree found in the tropical regions of America and Asia, and classed in the natural family of the *cucurbitaceæ*. It grows to the height of 20 feet, and bears a yellow-melon-like fruit called the papaw, which is eaten with sugar or salt and either raw or cook-

ed. Its milky juice forms a cosmetic, and also keeps worms away from the tree. The leaves are employed as a substitute for soap, and ropes and webs are prepared from the bark. It is said, also, that the flesh of animals which are fed upon the papaw is peculiarly tender.

CARIGNANO, a town of Piedmont, remarkable for its manufactures of silk twist and confectionery. Carignano gives the title of prince to the present royal house of Savoy. Pop. 7,873.

CARILLO, BRAULIO, a Costa Rica statesman, born in 1800 at Cartago, was assassinated in 1845. He was a member of the federal congress of Central America, and afterward elected governor of Costa Rica, of which state from 1838 to 1842 he was dictator. His dictatorship, although absolute, was of advantage to Costa Rica; for while he repressed all revolutionary tendencies with a strong hand, he devoted the energies of an active mind to the advancement of the material interests of the state. He adjusted its foreign debt, built roads and bridges, and above all, introduced the cultivation of coffee, which has now become the great staple of the country, and has raised it from the poorest to be the richest state of Central America. As dictator, Carillo dispensed with ministers of state, transacting all of its public affairs in person, with only the assistance of his wife.

CARIMATA, an island of the Malay archipelago, lying off the S. W. coast of Borneo. Its N. extremity is in lat.  $1^{\circ} 33'$  S., long.  $108^{\circ} 49'$  E.; area 153 sq. m. It has no permanent population, but is resorted to by the Bajans or Malay sea gypsies, for the purpose of collecting tripang, tortoise shell, and edible birds' nests. It has several prominent mountain peaks, one 2,000 feet above the level of the sea. Between this island and Billiton is the Carimata passage, a route for large ships during the S. E. monsoon.

CARIMON, GREAT AND LITTLE, 2 islands of the Malay archipelago, situated at the E. extremity of the straits of Malacca, a few m. S. of Singapore. The larger has area 72 sq. m., the smaller about 5 sq. m.; the former has a scanty population of about 500 Malay fishermen, and the latter is uninhabited. Both islands have a very sterile soil; but are supposed to be rich in tin ore, some fine specimens of which have been recently found upon Little Carimon. According to stipulations in the convention of 1824 between Great Britain and Holland, the Dutch claim paramount sovereignty over these islands.

CARINI, a Sicilian town, pop. 7,000, in the province of Palermo, and 12 m. W. of that city. It is beautifully situated on a small river of the same name, and has a fine old Gothic castle. Near Carini are the ruins of the ancient Hyccara, the birth-place of the courtesan Lais.

CARINTHIA, or KÄRNTHEN, a small duchy of Austria, forming part of the government of Laybach, in the kingdom of Illyria. It is a mountainous tract of country, divided since

1849 into 7 circles. Klagenfurth is the capital, where the diet of Carinthia is held, which is composed of 80 members. The Drave is its principal river, and the Klagenfurth or Wörth-See the only considerable lake. There are some manufactures, and there is a considerable trade in grain and cattle in Carinthia, but the principal wealth of the country is mineral, the great lead mines of Austria being located here. Area, 3,984 sq. m. Pop. 346,150, of whom 18,000 are Protestants, and the rest Catholics.

CARINUS, MARCUS AURELIUS, the elder of the 2 sons of the Roman emperor Carus, who conjointly succeeded to the throne on the death of their father, A. D. 284. His brother was supposed to have been murdered on his return from the East, and Carinus, ruling alone, became one of the most profligate and cruel of the Roman emperors. The soldiers having rebelled, and proclaimed Diocletian, Carinus collected the troops that were in Italy and marched into Mæsia to meet Diocletian, and quell the revolt. A decisive battle was fought near Margus, in which Carinus gained the victory, but in the moment of triumph he was slain by one of his own officers, whom the vices of the emperor had outraged.

CARIPE, a town and valley of Venezuela, in South America, 40 m. S. E. from Cumana. The valley is noted for a cavern frequented by a species of night-hawk (*caprimulgus*), the young of which are annually destroyed in great numbers for the sake of their fat, of which excellent oil is made. The cave is of limestone formation, 2,800 feet deep, and for some distance 60 to 70 feet high. Humboldt visited and described this cavern. The town is the principal station of the Chayme Indian missions.

CARISBROOKE, an agricultural village, once a thriving market town, of the isle of Wight, co. of Southampton, England, situated at the foot of a hill, near the centre of the island, in a parish of its own name, 1½ m. S. of Newport. Pop. of parish in 1851, 6,712. Under the independent lords of Wight it was the capital of the island, and afterward became the residence of the governor, who occupied a handsome mansion within the precincts of a ruined castle of great antiquity, crowning the hill back of the village. This castle is supposed to have been founded before the Roman invasion; was taken by Cerdic, the Saxon, in 530; enlarged by William Fitzosborne, a relative of William the Conqueror, and first lord of Wight, in the 11th century, and after many additions completed in the time of Elizabeth, when it covered an area of 20 acres. It was the place of confinement of Charles I. after his removal from Hampton Court, and a window is pointed out by which the royal captive made a fruitless attempt to escape. After his execution it became the prison of his 2 youngest children, the duke of Gloucester and the princess Elizabeth, the latter of whom died here. A ruined Cistercian priory, founded by

Fitzosborne, occupies an eminence on the castle. The priory church is now ruinous, and the other remaining portions are as sheds and stables. The village contains an infant school and several chapels for the poor. The parish contains infantry barracks, a house of industry for the whole island, an arranged juvenile reformatory, and several corn mills on the Medina river.

CARISSIMI, GIOVANNI GIACOMO, a composer, born at Venice in 1582, at a very advanced age. He was living in 1640. He was for a number of years director of the pontifical chapel at Rome, and at his death left an enormous number of compositions, including mostly of oratorios, masses, and operas, but a small proportion of which were published. We are indebted to Carissimi for his choral accompaniments to sacred music, and for great improvements in the style. He was also one of the first to write for the violin. His melodies are distinguished by a simplicity of spirit, and his harmony is wonderfully clear. His style, perfected by his pupils, like Monteverdi, Bassani, and Scarlatti, is considered the foundation of the music of the 18th century.

CARLEE, or KARLEE, a village in the collectorate of Poonah, p. of Bombay, 40 m. E. of Bombay. It is remarkable for a Buddhist cave-temple, the face of a precipice, about ½ of a mile up a steep hill, which rises 800 feet above the plain. A noble arch spans the entrance to the excavation, and on each side of the arch is a screen work, covered with naked female figures carved in alto-relievo. Above the arch are 8 lions placed back to back, on the top of the pillar; around the portico are several carved figures of elephants of great size, surmounted by a mohout and a howdah containing 2 persons. The length of the arch is 130 feet, and its width 40 feet. It has a row of sculptured pillars around the entrance, in a semicircle, and with its height 10 feet. Unlike the interior of a Gothic cathedral, there are several smaller excavations, which are intended as cells for monks or hermits. These are much dilapidated, but the architecture is in good preservation. The only objection to be seen is the mystical emblem of an umbrella.

CARLEN, EMILIA SCHMIDT, a Swedish novelist, born in Stockholm, 1810. Her first marriage was not a happy one. In 1841 she was married to her second husband, G. Carlen, a novelist. She was 28 years old when she published her first novel, "Waldemar," in 1851, an interval of only 13 years having elapsed. She had already published her 22d work, each of 1 or 2 volumes. Her subjects are usually selected from the lower ranks of society, and are more nearly transcripts of the facts of life than the fancies of the imagination. Some of her novels have been translated into English, and are in this country.

CARLETON, an eastern c

area 898 sq. m.; pop. 81,897. It is reached by a railroad extending from Prescott to St. Lawrence to Bytown on the Ottawa. CARLETON, SIR GUY, Lord Dorchester, a general, born in Ireland in 1724, died in 1800. He distinguished himself at the sieges of Miquilung, Quebec, and Belle Isle, and was killed in 1762, at the siege of Havana. In 1763 he was made governor of Quebec. On the nomination of Burgoyne to the command, he gave up his commission, but was appointed the following year lieutenant-general, and succeeded Sir Clinton as commander-in-chief in the colonies.

CARLETON, WILLIAM, a popular writer of tales, born in co. Tyrone, 1798. A peasant-son, he had obtained only an elementary education when at the age of 17 he was received into a school, a priest who kept a boarding-school in Drogheda, where he remained 2 years. He went to Dublin with only a few shillings in his pocket, and after struggling a number of years he was brought into notice by his "Traits and Stories of the Irish Peasantry." This was followed by other works, both pathetic and humorous. Several of his best works are of an English partisan character.

CARLI, GIOVANNI RINALDO, count, an Italian economist and antiquary, born at Capri on April, 1720, died in Milan, Feb. 22, 1799. In 1744 he was appointed by the senate of Venice to the professorship of astronomy and navigation in the university of Padua, and placed at the head of the Venetian navy. Affably discharging the duties of these offices for 7 years, he resigned them in order to devote himself entirely to his favorite studies. In 1754 he published the first volume of his great work on political economy, *Delle monete, e dell' influenza delle zecche d'Italia*, in 7 large vols.

In 1765 Leopold, duke of Tuscany, placed him at the head of the council of public instruction, and of the board of public instruction. He was, however, relieved from the labors pertaining to these offices several years before his death, though still retaining the emoluments accruing from them. During the leisure which the generosity of his patron thus afforded him he completed and published at Milan in 5 vols. his *Antichità Italiche*, a work on literary and artistic antiquities of his country, which has been much eulogized by Italian writers.

CARLI, DENIS, a Catholic missionary, born in 1630. He was sent in 1666 to Congo by the king on the propaganda, with father Angelo Guattini and 14 other friars. He could not long endure the heat of the climate and the fatigues of the mission. Carli, after bearing up for a long time with a severe malady, was obliged to return to Europe. He wrote an account of his travels, which was translated into French, English, and German.

CARLIN, THOMAS, one of the pioneers in Kentucky, and a governor of that state, born in

Kentucky in 1790, died Feb. 2, 1852. He removed to Illinois in 1818, and gradually accumulated wealth, and became known and respected among the scattered population about him. He was elected governor in 1838, and retained that office for 4 years, during a period of unusual and violent political excitement. Illinois, having engaged largely in internal improvements, suffered severely from the commercial revulsion which was then paralyzing the whole country. She was much in debt, and had within her borders no specie, and no available means of payment. The discussion of the slavery question, too, was then furious, and had just led to the tragic death of E. P. Lovejoy. At the same time the Mormons took up their position at Nauvoo, and politicians were beginning those movements for partisan ends, which seemed likely to throw the state into anarchy, and which ended ere long in the violent death of the Mormon leader. That Gov. Carlin, amid such a condition of affairs, was 8 times re-elected to the chief magistracy, affords a sure indication both of his popularity and his force of character.

CARLINA, a name given to a common genus of the thistle, from a tradition that its root was shown by an angel to Charlemagne, as a remedy for the plague which prevailed in his army. The carline thistle is found on dry sunny hills in most of the countries of Europe. Several species of it are mentioned in botany.

CARLINO, CARLO ANTONIO BERTINAZZI, a celebrated harlequin, born at Turin, 1718, died 1788. He entered the Sardinian army at an early age, but at the death of his father, who was an officer, he quitted the service, and taught fencing and dancing. His favorite occupation, however, was playing comedy with his pupils, and his success in it suggested the idea of making it a profession. At this time the harlequin of the Bologna theatre ran away from his creditors, leaving the manager in great perplexity. Bertinazzi undertook at a moment's notice to act in his place, and the public did not suspect the substitution until the 4th performance. His success in Italy was so great that, in 1741, he was invited to Paris, and succeeded there. He had a remarkable faculty of dramatic improvisations.

CARLISLE, the capital of Cumberland co., Pa., on the Cumberland Valley railroad, is a handsome town situated in the great limestone valley enclosed between the Kittatinny and South mountains. The surrounding country is level, productive, and highly cultivated. The town is well built, with wide and spacious streets, a public square, on which stand the county buildings, and public edifices of a superior order. Dickinson college, in this place, founded in 1788, and now under the care of the Methodists, is one of the oldest and most flourishing institutions in the state. There are 11 churches, 4 newspaper offices, a town hall, market-house, bank, and young ladies' seminary. Half a mile from the village are a school for cavalry practice, and barracks for 2,000 men,

built in 1777, chiefly by Hessian troops made prisoners at Trenton. Four miles N., in a valley of the Blue mountains, are Carlisle sulphur springs, a pleasant summer resort. During the whiskey insurrection, in 1794, Gen. Washington had his head-quarters at Carlisle, and a few years previous Major André passed some time here as a prisoner of war. Pop. in 1854, about 6,000.

**CARLISLE** (anc. *Luguvallio* or *Luguvallum*), the county town of Cumberland, England; pop. in 1851, 26,583; 300 miles N. N. W. of London, by railway. It is situated on the river Eden, and is a handsome town, owing to the improvements of late years. There are a custom-house, a news-room, a market, and a handsome railway station. A fine 5-arch bridge has been built over the Eden. There are several institutions for benevolent purposes. The cathedral church is a structure of the middle ages, not remarkable for size or beauty. There are 4 other churches, several chapels, an endowed grammar-school, British, national, and infant schools, 2 literary institutions, a mechanics' institute, a library, and a savings bank. The castle was built by the Normans in 1092, and many parts of it are in excellent preservation. It is still used as a garrison fortress. The city is one of the oldest in England, and was a Roman station. Its proximity to the border made it important as a military station in the border wars between the English and Scotch. In the civil wars Carlisle sided with the king, and it declared for the pretender in 1745. The inhabitants are principally employed in manufactories of cotton goods and gingham, foundries, hat factories, and dye works. It is connected with the Solway frith by a canal which gives it a share of the coasting trade. It gives the title of earl to the Howard family, and is a bishop's see. The municipal government is administered by 10 aldermen and thirty councillors. It returns 2 members to parliament, and is the centre of a poor-law union.

**CARLISLE, SIR ANTHONY**, an English surgeon and physiologist, born at Durham, 1768, died in 1840. He was surgeon of Westminster hospital for 47 years, and was knighted by George IV. He was the first to introduce the practice of holding public consultations in cases requiring operation; and also to substitute the straight-bladed amputating knife for the crooked one of former days. His chief work is his "Essay on the Disorders of Old Age."

**CARLISLE, FREDERIC HOWARD**, 5th earl of, a British statesman, born in May, 1748, died Sept. 4, 1825. In the house of peers he first distinguished himself by his recommendation of conciliatory measures toward the American colonies. He was one of the 3 commissioners appointed by George III. to visit America, and endeavor to restore peace. Accompanied by Gov. Johnstone and Mr. Eden, he set sail in 1778. The mission was unsuccessful in its main object, owing to the settled determination of the colonists to effect their entire separation

**CARLOCK**, a kind of isinglass, made of the sturgeon's bladder, and used chiefly for clarifying wine. It is imported from Russia.

**CARLOS**, DOX. I. Infante of Spain, son of Philip II., born at Valladolid, July 8, 1545, died July 25, 1568, in prison at Madrid, and was buried in the nunnery of the Dominican convent *El Real*. His mother, Maria of Portugal, died 4 days after having given him birth. He was sickly, and as he grew up, was subject to violent bursts of passion, which his father hoped would be subdued by the discipline of the university at Alcala. But as this proved of no avail, he was considered unfit for the throne, and in 1568 his cousins, the archdukes Rudolf and Ernest, were appointed in his stead presumptive heirs to the crown. When Alva was appointed in 1567 governor of Flanders—a post to which Don Carlos had aspired—the infante's exasperation led him to plan

his father, and to perpetrate  
 Don Juan, in consequence  
 put under arrest, Jan. 18,  
 subsequently transferred to the prison  
 died. His death as well as his life  
 many conflicting rumors. The in-  
 of temper between a rigid, iron-  
 like Don Philip, and a morbid,  
 youth like Don Carlos, the fact that  
 he had been engaged to Elizabeth of  
 who subsequently became his step-  
 is sympathy with the revolt of the  
 and his hatred of Alva and the  
 of his father, all conspired to  
 melancholy fate of the infante with a  
 romance, which has been poetically  
 by Alfieri, Campistron, Otway, and  
 above all by Schiller. II. CARLOS  
 DOB, pretender to the crown of Spain,  
 ing Charles IV., born March 29,  
 in Trieste, March 10, 1855. Many  
 ponents of the constitutional régime  
 restored in 1820, gathered around  
 s, hoping that, after the decease of his  
 brother Ferdinand VII., he would  
 e throne. But these hopes were  
 by Ferdinand's marriage with Maria  
 and by the abrogation of the Salic  
 h placed Isabel upon the throne.  
 when Ferdinand was supposed to  
 eve of death, the Carlists succeeded  
 ng from him a decree reëstablishing  
 law, and thus excluding Isabel; but  
 red his health, and the fraud prac-  
 him was immediately redressed.  
 w. i. Ferdinand died, Don Carlos  
 himself king. Maria Christina, the  
 anded him as a rebel, and concluded  
 ain, France, and Portugal, the so-  
 druple alliance, the practical effect of  
 us to expel Don Carlos and Don  
 he champions of absolutism, from  
 l Portugal. On July 1, 1834, Don  
 ft England, whither he had fled,  
 gling himself into Spain, succeeded in  
 civil war in the northern provinces,  
 ed for several years, Don Carlos elud-  
 gillance of his opponents until 1839,  
 was compelled to leave the Spanish  
 and to betake himself to France,  
 on his refusal to renounce his claims,  
 y order of the French government,  
 t Bourges. The decree which ordained  
 l expulsion from Spain was, by  
 vote, confirmed by the cortes in 1836.  
 e adopted the name of count of Mo-  
 ated in favor of his eldest son the count  
 nolin, and on receiving permission  
 France, took up his abode in Austria.  
 t wife was Maria Francisca de Assis,  
 of King John VI. of Portugal, who bore  
 as, Don Carlos in 1818, Don Juan Car-  
 l, and Don Fernando in 1824. His 2d  
 m he married in 1838, and who surviv-  
 Maria Theresa, infanta of Portugal and  
 of Beira, widow of the infante Pe-

dro, of Spain, and mother of the infante  
 Sebastian of Portugal. III. CARLOS LUIS MA-  
 RIA FERNANDO, the eldest son and heir of  
 Don Carlos the pretender, born Jan. 31,  
 1818. In 1846 he left Bourges, where he had  
 resided with his father, and took up his abode in  
 England under the name of the count of Monte-  
 molin. In April, 1849, he made an attempt to  
 introduce himself in disguise into Spain, but he  
 was arrested, detained from April 5 to the 10th  
 in the citadel of Perpignan, and on April 15 he  
 was again in London. On July 10, 1850, he  
 married Maria Carolina Ferdinanda, a sister of  
 the present king Ferdinand II. of Naples.

CARLOVINGIANS, or CAROLINGIANS, an  
 illustrious imperial family who, during the 9th  
 and 10th centuries, gave sovereigns to Ger-  
 many, France, and Italy. Their origin is  
 traced back to Arnulf and Pepin of Landen,  
 2 powerful Frankish lords of Austrasia in the  
 beginning of the 7th century, while they de-  
 rived their name from Charles Martel, the con-  
 queror of the Saracens at the battle of Poitiers,  
 in 732. This hero, the son of Pepin of Herstal,  
 was the founder of the greatness of his house.  
 Satisfied with the titles of duke of the Franks  
 and mayor of the palace, under the weak Mero-  
 vingian kings, he ruled with an absolute power  
 the Frankish kingdoms of Austrasia, Neustria,  
 and Burgundy. His son, Pepin the Short, con-  
 fining within the walls of a convent the last of  
 those kings, Childeric III., assumed the royal  
 title, and his grandson, Charles, afterward  
 known as Charlemagne, having extended his  
 conquests as far as the Garigliano on the S.,  
 the Oder on the N., and the Carpathian moun-  
 tains and the Theiss on the E., restored the  
 western Roman empire, and consequently styled  
 himself emperor. This Carolingian empire,  
 consisting of a motley assemblage of nations  
 brought together by conquest and decidedly  
 hostile to each other, could not long outlive its  
 founder; it began indeed to totter on his death,  
 and then gradually fell into ruins. Its final dis-  
 ruption, taking place in 888, was followed by  
 no less than 9 separate kingdoms; the most  
 important of which, Germany, France, and  
 Italy, continued for a while under the sway of  
 the descendants of Charlemagne. We subjoin  
 a list of the sovereigns of this family: EMPER-  
 ORS. Charlemagne, 800-814; Louis the Weak,  
 or Débonnaire, 814-840; Lothaire, 840-855;  
 Louis II., son of Lothaire, 855-876; Charles  
 the Bald of France, 875-877; Charles the Fat  
 of Germany, 881-887. This was the last of  
 the actual emperors of the Carolingian dy-  
 nasty; but several princes, most of them in the  
 feminine line, Guy of Spoleto, Lambert, Arnulf  
 of Carinthia, Louis and Berenger of Italy,  
 boasted of the empty title.—KINGS OF GER-  
 MANY. Charlemagne and Louis the Weak were  
 followed by Louis the German, 840-876; Louis  
 the Younger or of Saxony, 876-882; Charles  
 the Fat, 882-887; Arnulf of Carinthia, 887-  
 899; Louis the Child, 899-911. To the extinct  
 house of Charlemagne those of Saxony and

**Franconia succeeded.—KINGS OF FRANCE.** The Carolingians here are styled the 2d race of the Frankish kings, and succeeded the Merovingians; Pepin the Short, 752-768; Charlemagne, 768-814; Louis the Débonnaire, 814-840; Charles the Bald, 840-877; Louis the Stammerer, 877-879; Louis III. and Carloman, 879-884; Charles the Fat of Germany, 884-887; Charles III., the Simple, 893-923; Louis IV., D'Outremer (ultramarinus), 936-954; Lothaire, 954-986; Louis V., the Idle, 986-987. On the death of this prince, Hugh Capet was elected king by the nation, to the exclusion of the lawful heir, Charles, duke of Lorraine, the uncle of Louis V. Hugh was the head of the 3d dynasty, called after him Capetians.—**KINGS OF ITALY.** Charlemagne, 774-781; Pepin, his son, 781-812; Bernard, 812-818; Louis the Débonnaire of France, 818-820; Lothaire, 820-855; Louis II., 855-875; Charles the Bald of France, 875-877; Charles the Fat of Germany, 879-881; Guy of Spoleto, 881-888; Berenger, 888-894 and 905-924; Lambert, 894-900; Louis, 900-905; Hugh of Provence, 926-947; Lothaire, 945-950; Berenger II. and Adalbert, 950-961. On the death of Adalbert, the kingdom of Italy was united by Otho the Great to the German empire.

**CARLOVITZ, CARLOVICZ, or CARLOVITZA,** a military frontier town or captaincy of Austrian Slavonia, pop. about 5,800, in the district of Peterwardein, with a cathedral, 3 churches, a Greek seminary, a lyceum, a Roman Catholic academy, a brisk transit trade and fisheries, an extensive export trade in wormwood and wine, the quantity of the latter exported in some years amounting to 1,800,000 gallons. The great wine mountain in the vicinity of Carlovitz yields the best and strongest qualities of Hungarian wines. The Carlovitz red wines are especially renowned. The town is the see of a Greek archbishop—the only Greek prelate of that rank within the Austrian dominions. A peace was concluded here in 1699, for the term of 25 years, between Austria, Poland, Russia, Venice, and Turkey, by the mediation of England and the Netherlands. By the terms of this treaty, the emperor of Austria received Transylvania and Bacska; Russia, Azof; Poland received back Podolia, the Ukraine, and Kamieniec, but ceded some Moldavian towns. Venice retained the Morea, and Turkey remained in possession of Temesvar. During the revolutionary era of 1848-'49, Carlovitz was the focus of the Servian rebellion against Hungary, and the theatre of collision between the Servians and the Magyars, and at a later period between the Hungarians and Austrians.

**CARLOW** (anc. *Catherlogh*), a county in the province of Leinster, Ireland; area, 846 sq. m.; pop. in 1851, 68,075. It is level except on the S., where the Blackstairs and Mt. Leinster ranges give a rugged character to the district. The rivers are the Slaney and the Barrow. Carlow is of granite formation, covered in the

plains by the eminences of the Blackstairs. It is a fertile and productive county, the soil is rich and cultivated, and cereals, roots, &c., are grown luxuriantly. The county is, from its central position, with that of the English counties, struggling to recover their former greatness. In 1798 Carlow was the seat of a rebellion. The present condition is much improved by the presence of the proprietors, and the county is seen in the skilful and productive hands of the land. The antiquities are the cathedral at Old Leighlin, the Butlers at Clonmore, in fine preservation, and several other remains in various parts of the county. The towns are Carlow, and Bagnalstown. There are 12 schools, attended by 6,900 pupils or more.—**CARLOW,** a parliamentary borough, parish, and capital of the above-county, 56 m. S. W. from Dublin by railway; population, 10,292. The town is at the confluence of the Burren with the Suir. The principal edifices are a fine castle, a gaol, a parish church, a Roman Catholic school and college, 2 nunneries, a dispensary, infirmary, hospital, work-house, &c., and 2 bridges. There are several national schools. The population is engaged in the provision of flour mills, and it is an important market for agricultural produce of the county. The castle, of which the remains are still visible, was built in the 12th century, was the town, which was made a borough.

**CARLSBAD,** a Bohemian town, 110 m. of Prague, famous as a watering-place. It takes its name from the emperor Charles IV., who, in the middle of the 14th century, was the first to avail himself of the power of the springs, and whose name is on the market place. Next to Charles IV., the greatest benefactor of the town was a nobleman, the earl of Findlay, who laid out some beautiful gardens in his honor was erected in the forest adjoining the town. Excavations have frequently been made to this spot and to the neighboring mountains. Many eminent persons, as Linnaeus, Berzelius, Friedrich H. Werner, and, above all, Goethe, have been frequenters of the place. The chief ingredients of the springs are sulphate of soda, carbonate of soda, and common salt; and the principal springs are the Strudel, Mühlbrunnen, and Schlossbrunnen, having respectively a temperature of 165°, 138°, 147°, and 123° F. The waters are efficacious in liver and kidney diseases, and in a variety of other complaints. After the termination of the Carlsbad season, many of the visitors resort to the waters of Teplitz, Franzensbad, Ischl, &c. Since 1848,

of the springs are exported to dis-  
 without being deteriorated by the  
 In 1858, a new spring was discovered  
 unl, containing carbonic and phos-  
 de of iron.—In August, 1819, a min-  
 ngress was convened at Carlsbad by  
 n powers, principally with a view of  
 he seditious spirit which at that time  
 manifested itself at the universities  
 g the turners. The assassination of  
 by Sand afforded a pretext to the  
 overnments to carry out their long-  
 designs; and by the decrees pro-  
 at Carlsbad on Sept. 20, 1819,  
 henschaften, or political unions of  
 its, were declared illegal, the press  
 d, and other stringent restrictive  
 adopted. On April 2, 1848, however,  
 ees, as far as they had been approved  
 erman diet, were rescinded by that

BURG, or KARLSBURG, a fortified  
 Transylvania, S. of Klausenburg;  
 it 12,000. It contains many fine  
 fices, among which the citadel, the  
 the bishops of Transylvania, the  
 tholic cathedral, and the gymnasium,  
 larly worthy of note. A considerable  
 the inhabitants consists of Jews, who  
 peculiar privileges.

CRONA, a maritime province of  
 ounded S. and E. by the Baltic, W. by  
 tadt, and N. and N. E. by the prov-  
 exiö and Kalmar; area 1,185 sq. m.;  
 55, 111,255.—The capital of the above  
 of the same name, stands at the south-  
 nity of Sweden, on 5 small islands,  
 connected with each other and with  
 and by numerous bridges, and is the  
 tation of the Swedish navy. The town  
 fortified, and has a safe and capacious  
 rich has everywhere sufficient depth  
 for the largest vessels. The houses  
 uilt, though wood is very much used  
 onstruction. Carlscrona has an ex-  
 aval arsenal and dockyard, from  
 separated by a wall. Its principal  
 re the council-house, the prefect's  
 the public schools, and the churches.  
 manufactures are naval equipments,  
 hs, tobacco, and refined sugar. As  
 rt of Gothenburg, it carries on a  
 le export trade in metals, potash,  
 Baltic produce. Pop. in 1855, 14,-

HAMN, a fortified seaport town of  
 n the Baltic; pop. in 1855, 5,214. It  
 ilt, has a small but secure harbor, a  
 et-place, a town-house, two churches,  
 factories, and an active trade in iron,  
 ash, pitch, and tar.

RUHE, capital of the grand duchy  
 and of the circle of Middle Rhine,  
 ated plain of the Hartz Forest, within  
 e Rhine, 39 m. of Stuttgart, and an  
 e of Baden-Baden, and on the railway

line between Mannheim and Basel; pop. in 1855,  
 25,160. The town was built around a hunting  
 seat erected in 1715 by Charles William, mar-  
 grave of Baden, whose remains are interred be-  
 neath the pyramid dedicated to his memory upon  
 the market-place. Carlsruhe was designed in the  
 form of an extended fan round the grand-ducal  
 palace, from which, as a centre, 32 public ave-  
 nues radiate, 17 of which, forming the principal  
 streets, have been built on both sides. The new  
 theatre and the academy are the finest buildings  
 of Carlsruhe. The palace, erected in 1751 on the  
 site of the old structure, presents nothing remark-  
 able except the *Bleythurm* (lead tower), which  
 affords a fine view over the city and surround-  
 ing country. Of the public squares, the palace  
 and market squares are the most beautiful. The  
 educational institutions of Carlsruhe are remark-  
 able, especially the polytechnic institute, which is  
 attended by many pupils from distant countries.  
 The lyceum, the seminary for teachers, the  
 military academy, the academy of design,  
 painting, and engraving, the cabinet of natural  
 history, the gallery of engravings, the grand-  
 ducal archæological cabinet and that of medals,  
 the court library with 80,000 volumes—all these  
 afford evidences of the excellent arrangements  
 which exist at Carlsruhe for the promotion of  
 knowledge. The fine public parks which are  
 thrown open to the people, and the trees planted  
 in the squares, constitute the chief beauties of  
 the place. There are several palaces belong-  
 ing to the Baden nobility, and not less than 90  
 public buildings, including the churches, the  
 mint, the school-houses, the hospitals, &c., or  
 about 1 public building for every 330 inhabitants.  
 Among the hospitals is one endowed with  
 \$44,000 by the celebrated London tailor Stultz,  
 who was a native of Baden, and whose munifi-  
 cence has been rewarded by the grand duke with  
 the title of baron. Two-thirds of the inhabitants  
 are Protestants, the remainder Catholics and  
 Jews. The new Protestant church, built in 1807,  
 is a noble Roman structure. The synagogue is  
 in oriental style, and the new Catholic church  
 has a fine portico with 8 Ionic pillars. The  
 Carlsruhe railway depot is a rather showy but  
 at the same time imposing building, and has a  
 holiday look, as if people travelled more in  
 search of pleasure than of business. The *Karls-  
 ruher Zeitung* is the principal newspaper of  
 the town.

CARLSTAD, a province of Sweden, between  
 lat. 59° and 61° N., and lon. 12° and 14° 30' E.,  
 bounded on the S. by Lake Wener and the prov-  
 ince of Wenersborg, on the W. by Norway, and  
 on the N. and E. by the provinces of Öerbrö and  
 Faelun; area, about 7,000 sq. m. The popula-  
 tion has increased from 140,977 in 1815, to 186,-  
 788 in 1835, and 232,521 in 1855. The prov-  
 ince is rich in iron, copper, and lead mines, and  
 the trade in iron is of great importance.—CARL-  
 STAD, the capital of the province, stands on an  
 island of Lake Wener, 160 m. W. of Stockholm.  
 Among the public buildings are a cathedral, a  
 college, a cabinet of natural history, and an ob-

servatory. The exports are copper, iron, corn, salt, and timber. The opening of the Gotha canal, which unites the lakes of Wener and Wetter and the Baltic with the Cattegat, has had a favorable effect upon the commercial activity of Carlstad. The town and its vicinity are noted for fine advantages for fishing and shooting. Pop. in 1855, 4,128.

**CARLSTADT, ANDREAS**, a German reformer, born at Carlstadt, in Franconia, about 1488, died in Basel, Dec. 25, 1541. He adopted the name of his native town, but his real name was Bodenstein. He took his degree of D.D. at Wittenberg, was appointed professor in that university, and subsequently advanced to the dignity of canon, dean, and archdeacon. From the very commencement of the reformation he was one of its firmest and most zealous adherents. In 1519 he held a controversy at Leipsic with Eckius on the doctrine of free will, in which he proved himself so decided an antagonist of Catholicism, that he was soon after excommunicated by the pope. This severity on the part of his opponents, and his own ardent and impulsive temperament, hurried him into a course, in 1521, which Luther and Melancthon severely condemned. He entered the great church of Wittenberg at the head of an infuriated multitude, and destroyed the crucifixes, images, and altars of that venerable fane. He rejected the title of doctor, abandoned his professorship, applied himself to manual labor, and affirmed that learning was useless to biblical students, who ought rather to toil like him, with their hands than waste their time in the acquisition of unprofitable knowledge. After Luther's return from the Wartburg, however, the old order of things was restored in the church of Wittenberg, but Carlstadt went 2 years afterward (1524) to Orlamunde, a small town in the electorate of Saxony, where he forcibly took possession of the pulpit, creating disorder, which was again denounced by Luther. Expelled from Saxony, he brought forward the question of the real presence of the body and blood of Christ in the eucharist, avowing himself the antagonist of Luther, and defending the extreme Protestant view of that doctrine. Suspected of sympathizing with the peasants' war in Franconia, he continued to give umbrage to the authorities, and led for several years an unsteady nomadic life, until, reduced to extreme poverty, he appealed to Luther, who generously granted him assistance and a domicile near Wittenberg, under the condition that he would refrain from giving utterance to his religious opinions. Having quietly spent about 8 years in agricultural and commercial occupations, he again came forward in 1528 with several violent publications; and to escape from the indignation of Luther, against whom he was believed to have planned conspiracies, he betook himself to Denmark, East Friesland, Strasbourg, and finally to Zürich, where he was kindly received and assisted by Zwingli. He was appointed archdeacon in the latter city, and from

1534 to

nuptial bonds.

**CARLUKE**, a municipal borough and parish of Scotland, county of Lanark, on the Clyde: pop. of the parish in 1851, 6,288; of the town, 2,845. There is a handsome church here, and since the introduction of the cotton manufacture the place has increased rapidly. The banks of the Clyde in this vicinity are famous for orchards, some of which are of vast extent. The antiquary Major-Gen. Roy, and the sculptor Forrest were natives of this parish.

**CARLYLE, JOSEPH DAWSON**, an Oriental scholar, born in Carlisle in 1796, died at Newcastle-upon-Tyne in 1804. He was educated at Cambridge, and elected to the Queen's college, where in 1811 he was appointed professor of Arabic. He was also chaplain to the embassy at Constantinople, and collected there valuable Greek manuscripts. He projected a revised edition of the Septuagint with the aid of these manuscripts, and lived to complete his plan. He published a translation of an Arabic volume of translations of Arabic poetry from the earliest times to the extinction of the Arabic language, and a posthumous volume of poems and the scenes of his travels; and an edition of the Arabic Bible.

**CARLYLE, THOMAS**, a British author, born in 1795, in the parish of Middlebie, near the hamlet of Ecclefechan, in Dumfriesshire, Scotland. His father was a small farmer of that district, and his mother descended from a family of the same neighborhood, both being represented as persons of extraordinary native sagacity and force of character. He was the eldest of their children, and received the best part of his education at home, though he enjoyed, besides, the advantages of a school at Annan, and of the university at Edinburgh. At school he formed the acquaintance of Edward Irving, then in his 16th year, and on a visit to the teacher, "fresh from college, with prizes, high character, and promise," and full of "hope, joy, and healthfulness without end." As Carlyle was but 14, there can be no doubt that the extraordinary mind of Irving, "opening a whole wonder-land of knowledge," exercised a powerful influence on his dawning faculties. He has left a record of it in the beautiful and touching sketch of the famous preacher which he contributed to "Fraser's Magazine" in 1835, when the "foul Ocean draught of popular applause having maddened his intellect, death fell upon his diseased and prematurely aged body." "But for Irving," he says, "I had never known what the communion of man with man means. He was the freest, brotherliest, bravest human soul

ver came in contact with: I call him, on whole, the best man I have ever found in world, or now hope to find." This was an able witness of friendship at a time when Irving had fallen under the contempt, as that of an impostor or a . . . At college, however, Carlyle was distinguished for his attainments in classics, and the pursuit which he proposed was the Christian ministry. But he sought the college libraries in the search of knowledge, and made himself famous as few young men have done, with forgeries and the old English literature. . . . His vacations were passed in rambling through the hills and moors of his native land. . . . years after leaving college, about 1820, he engaged himself in teaching in the family of Mr. John Buller, when he became convinced that the ministry, but general literature was his vocation. His first work was a translation of Legendre's "Geometry," to which he prefixed an "Essay on Proportion;" and the next year, "Life of Schiller," the beautiful prose, fine sentiment, and manly sentiment of which must have convinced his friends that he had rightly chosen his calling. It was originally published in the "London Magazine" for 1823-'4, to which Thomas Hood, Lamb, De Quincey, and Allan Cunningham were contributors. At the same time he translated Goethe's *Wilhelm Meister*, and astonished the critics by the facility with which the ease, the power, and the force of that remarkable work had been translated into another tongue. It was followed, in 1825, by the "Specimens of German Romance," in which the exquisite tales of Tieck, Jean Paul, and Hoffmann received for the first time adequate English dress. He had been in the previous year to Miss Welch, a descendant of John Knox, who brought to him the best virtues and graces of the Scottish female character. Residing for a while in Edinburgh, they then removed to an estate at Craigenputtock, in the wildest Dumfriesshire, which he has described in earnest and poetic spirit in a letter to Thomas Hood, with whom his translations had brought him correspondence. "Our residence," he writes, "is not in the town itself, but 15 miles N. W. among the granite hills and black moors, which stretch westward through Galloway almost to the Irish sea. In this wilderness of heath and rock, our estate stands forth, a small oasis, a tract of ploughed, partly enclosed, cultivated ground, where corn ripens, and the wind affords a shade, although surrounded by wild heaths and rough-woolled sheep." He then proceeds to paint a charming picture of rural and domestic comfort. "Piled up on the little library-table," he does not forget to add, "are a cart-load of French, German, American, and English periodicals, whatever they may be." It was in this solitary, but delightful residence, that Mr. Carlyle began his papers for the Edinburgh Review, the first of which that

appeared was the essay on Jean Paul, which was followed by that on German literature, and then by that on Burns. These alone, had he put his name to them, would have given him a first rank among the writers of English. Their profound thought, their searching analysis of character, their deep fountains of noble sentiment, their sinewy language, and their varied learning, stamped the author as not only one of the great thinkers, but as one of the most eloquent writers of his age. All the while he was engaged on lesser articles for the "Edinburgh Encyclopædia," among which those on Montaigne, Montesquieu, Pitt, and Nelson are ascribed to him. He wrote also for the "Foreign Quarterly," and for the magazines. In the intervals of leisure, a run over to Edinburgh brought him into contact with Wilson, Jeffrey, and other literary celebrities, whose conversation, doubtless, recreated and quickened his spirits, as well as his mind. In the course of the years 1833-'34, he published in "Fraser" the most peculiar and remarkable of all his works,—the quaint, the whimsical, the profound, the humorous, and the poetic "Sartor Resartus," in which he seems to have poured all the accumulated treasures of his mind and heart. Under the eccentric guise of a vagabond German philosopher, and on the homely topic of the philosophy of clothes, he has brought together much of the deepest speculation, the finest poetry, the noblest morals, and the wildest humor that his or any age has produced. The strange conceits of it, and the barbaric rudeness of the style, not untouched with more than barbaric splendor, repelled the booksellers from it, as from some huge, unknown bomb-shell, charged with all manner of combustibles. Nor did it readily find a public, when published, but, like many other new things, had to create its own audience. Since then it has come to be more enthusiastically and fitly appreciated. During the negotiations for the printing of "Sartor," Mr. Carlyle removed to London (1834), and has continued to reside there in a suburban neighborhood at Chelsea. His marked originality won him many admirers, while his geniality and humor made him many friends; and, from the publication of "Sartor" up to the present hour, his pen has been recognized as one of the great powers of English literature. It was not, however, till the year 1837, when he brought forth the "French Revolution, a History," that his name was attached to his works, and he became known beyond a select and inner circle. While he was preparing that marvellous production, it is said, the manuscript of the 1st volume was burnt, and he was compelled to go over the vast field of reading and labor which it embraced anew. Not so much a "history"—as it supposes in the reader a considerable familiarity with the events which it professes to portray—as a grand collection of historical pictures, painted with fire and darkness, it may safely be pronounced the most

luridly vivid and fearful presentation of that stupendous epoch which has yet been made. The most animated delineations of Thiers are tame beside it, and the most brilliant sketches of Lamartine mere outlines in charcoal and chalk. But it has this defect, that the philosophy of it is contemptuous and mocking, and it depicts the varied and gigantic characters which stalk across the scene, not so much as responsible and living mortals, as the mere mechanical implements of some tremendous and irresistible destiny. The honor of collecting the "Miscellanies" of Mr. Carlyle belongs to Mr. R. W. Emerson, of Concord. Mr. Carlyle's studies for the "French Revolution" deeply interested him in social problems, the first fruits of which interest appeared in the "Chartism" of 1839. It was his first dash at the great practical questions of the day, which showed that, although he had not considered them as profoundly or as hopefully as he ought to have done, he had yet laid them close to his heart. They were interrupted for a time by a series of lectures which he delivered in London from 1837 to 1840, to numerous and excited audiences, on "German Literature," the "History of Literature," the "Revolutions of Modern Europe," and "Heroes and Hero-Worship," the last of which alone has thus far been published. It was an evidence to most of his readers of two things: 1, that the strangely abrupt and tortuous style, which was perhaps very well adapted to the peculiar objects of "Sartor" and the "French Revolution," was now a chronic malady with him; and, 2, that the beautiful reverence for silent intellectual force which marks his articles on Goethe, Burns, Schiller, &c., had been converted into a worship of mere force of will and strong animal impulse. The tendency to this substitution was already to be recognized in the loud preference for Danton and Mirabeau in the "French Revolution" to Robespierre; but it was made more obvious still in the "Heroes," and in his next work, "Past and Present." In 1845 he edited, as they had never before been edited, with some insight into the grand character of the man, the "Letters and Speeches of Oliver Cromwell," in which work his literary career appears to have culminated. The "Latter-Day Pamphlets," which appeared in 1850, and in which he resumed his discussions of social questions, are only remarkable for a violent imitation of himself, and not of his better self. The "Life of John Sterling," in 1851, evinced some return to his ancient and genial methods both of expression and thought, but the subject was scarcely large enough to arouse his powers. His "Collected Works" were published in London in 1857-'58. The first 2 volumes of the "Life of Frederic the Great," of Prussia, to which he had been devoted for several years past, were published in Sept. 1858. A "Memoir of Mr. Carlyle, with Passages selected from his Writings," was published by Thomas Ballantyne in 1855. He has been most elaborately characterized in an article

in the "Bayne's" there is a vein the unevangelical the time has hardly a truthful appreciation of influence upon the destiny of the 19th century. entire significance has not yet been developed. In the opinion of many, he has given a new turn to the whole of English thought and criticism. He has imparted to the art of writing a nobler tone, opened it to a wider range, infused into it a profounder spirit: no one more than he can quicken the impulses of young writers, as with the sound of a trumpet—no one lead them to richer or better sources. If his wild and obnoxious manner has somewhat corrupted style, his lofty and suggestive thought has stimulated sentiment; if his scheme of philosophy is imperfect as a whole, his occasional and disconnected views are full of grandeur, of beauty, and of truth; he is not always the safe guide, but is always an invaluable help; and though our benevolent feelings are repulsed by the stern and remorseless indifference to the individual which shows itself in his later works, we may still discover beneath the incrustation of scorn and callousness which has grown over him a noble, fiery soul.

CARMAGNOLA, a Sardinian town, pop. about 13,000, on the river Mella, in the province of Turin, famous for its extensive trade in silks and for its silk fairs, which annually take place in June. The town is on the railway line between Turin and Nice, contains several fine streets and public squares, 5 churches, 3 convents, and a hospital.

CARMAGNOLA, FRANCESCO, a famous condottiere, whose real name was Busone, born about 1390, in the above-described town of Carmagnola, the name of which he adopted. The son of a peasant, he was a herdsman in his youth; but enlisting in the service of the duke of Milan (Filippo Maria Visconti), he rapidly rose in rank, and aided his master in regaining a great part of Lombardy, and in extending his possessions. The duke, however, became suspicious of his loyalty, confiscated his property, cast his wife and children into prison, and banished him; upon which Carmagnola entered the service of the republic of Venice, from which he received the appointment of gonfaloniere. He wrested Brescia from the duke of Milan, and entirely routed his army at the battle of Macalo in 1427. After the battle he released his prisoners, which was frequently done at that time by condottieri, but incurring the suspicions of the Venetian senate for doing so, and his subsequent military operations not proving successful, he was recalled to Venice, under the pretext that his advice was needed for affairs of state, placed under arrest, accused of treason, put to the torture and beheaded, May 8, 1432.

**CARMAGNOLE**, a song of the French reign commencing with the words:

*Madam' Veto avoit promis,*

ending with:

*Dansons la Carmagnole,*

*Vive le son*

*Du canon!*

The name was also applied to the revolutionary costume worn by many of the terrorists; is further applied to Savoyards in so far as they are supposed to have emigrated from France; and the same town, whether or not, is also supposed to be in some way associated with the origin of the two different meanings of the word.

**CARMEL**, a range of limestone hills in N. W. France, terminating at the sea by the promontory of Mount Carmel. Carmel is celebrated for the fertility of its sides and slopes, and although the olive has ceased, enough remains in the soil to grow the wild olive, and the pasture, to bear a good reputation. It is the scene of some of the great events of biblical history, and was the seat of the prophet Elijah from the tyrant Ahab and the hate of Jezebel. The city of Tyre runs at the foot of Carmel.

**CARMELITES**. Mt. Carmel appears to have been a favorite place of resort for Jewish ascetics, often furnished a secure and solitary retreat to the prophets Elijah and Elisha. In the Christian era, hermits were fond of settling themselves in the same region, and hence the Carmelite tradition that their order was founded by the prophet Elijah upon Mt. Carmel. The following is a worthy historical account of the foundation of this celebrated order, is that given by the learned Bollandists. A crusader of the 12th century, Berthold of Calabria, made a vow in the heat of battle to embrace a monastic life if he should meet the victory; and the battle being decided in his favor, he fulfilled his vow by retiring to a cave on Mount Carmel, called the cave of the prophet Elijah. He was accompanied by some others, and the increasing numbers made it soon necessary to build a monastery. Berthold's successor obtained a rule from Albert, patriarch of Jerusalem, which was confirmed by Honorius III. in 1224. Under Alanus, their 5th general, the Carmelites migrated to Europe, to escape the persecution of the Saracens, and a rule, suited to the western climate, was adopted and approved by Pope Innocent IV. This order, which was very early extended itself widely, and gained a great reputation in Europe. The female branch of the order was founded by F. John Soreth, in the 15th century. In process of time, relaxation having been introduced into the original rule of Albert, as modified by Innocent IV. This resulted in a division of the order into 2 branches—one of the strict and one of the stricter observance. The former of monks in the milder observance is

now about 700; in the stricter, about 1,200. There are 90 convents of Carmelite nuns, in each of which the number is restricted to 21. One of these convents is in Baltimore, having been transplanted from the lower counties of Maryland, where it was founded in the latter part of the 18th century. The Carmelites of Baltimore formerly kept an academy for young ladies, but they have recently given it up, and with some few necessary exceptions, keep the strict rule of St. Teresa. Notwithstanding their austere life, it is remarkable that they generally enjoy good health, and frequently attain to a very advanced age.

**CARMER**, JOHANN HEINRICH KASIMIR, count, a Prussian statesman, born at Creuznach in 1721, died at his estate of Rützen, near Glogau, in 1801, celebrated for his law reforms, which, under the name of *Allgemeines Landrecht* (general civil law), became the new Prussian code of law, ratified by Frederic William II., June 1, 1794.

**CARMINE**, a pigment of a brilliant scarlet color, prepared from the boiling solution of cochineal by adding alum and carbonate of potash or soda, and boiling for a few minutes. The liquid is strained, and allowed to stand for some time, when the combination of cochineal and alumina, called carmine, is deposited. Oxide of tin is also made use of to obtain a similar precipitate. The separation of the precipitate is hastened by the use of some albuminous matter, as white of egg or fish-glue, by the coagulation of which the carmine is collected. Several processes are in use for the preparation of the most beautiful carmines. That made by Madame Cenette of Amsterdam is said to be of so brilliant a hue as to be almost painful to the eye. It is thus given in the *Annales de l'Industrie*: Two pounds of the finest cochineal in powder are to be put into a vessel containing 6 pailfuls of boiling soft water; and the boiling is to be continued for 2 hours, when 3 ounces of pure saltpetre, and soon after 4 ounces of binoxalate of potash, are to be added. After 10 minutes the boiling is to be discontinued, and the liquor is allowed to stand for 4 hours. It is then to be drawn off with a siphon into flat glazed dishes, and left for 3 weeks. A coating of mould forms upon the surface, which is to be nicely removed in one piece; or if any fragments remain, they must be taken out with the greatest care. The liquor is again to be drawn off with a siphon, leaving the cake of carmine in the dish, when it is to be carefully dried in a clean shady place. —As carmine is desired to be used principally as *rouge*, for imitating the soft blush upon the fairest cheeks, it is an especial object to obtain it of the highest degree of perfection; and so delicate are the processes of the French that the result is affected by the condition of the weather, and the best carmine is only made on bright sunny days. Sir Humphry Davy relates an incident of an English manufacturer agreeing to pay £1,000 to a Frenchman for the secret by which the latter made so superior an article; when it appeared

that the only difference in the two modes of preparation, was that the Frenchman always selected such fine bright weather as the Englishman could not hope to command in his own country. Carmine was accidentally discovered by a Franciscan monk at Pisa, in preparing a medicine of cochineal and salt of tartar. The beautiful precipitate, however, was soon found to be much better adapted for giving a rich bloom to the cheeks of fair maidens; and hence it soon assumed an importance which it still retains. Its use is extended to the manufacture of the best red inks, to silk dyeing, to the preparation of artificial flowers, and as a pigment in water colors and miniature painting. Its high value has rendered it an object to prepare it of different degrees of purity, according to the quantity of alumina mixed with it; and it is also adulterated by mixing with it more or less of the cheaper vermilion. As the pure carmine is wholly soluble in ammonia, these ingredients are easily detected, separated, and estimated.

CARMOE, or KARMOE, an island of Norway, lying at the entrance of Bukke fiord, in the North sea, 21 m. long, average breadth 5 m.; pop. 6,890.

CARMONA, a Spanish town, pop. in 1852, 15,121, 18 m. from Seville, is a place of much antiquity, and was once strongly fortified. It stands on an isolated hill, surrounded by old Moorish walls, has venerable churches, a university of Saracenic architecture, several manufactories, and an annual fair.

CARNAC, a village of France, in the department of Morbihan, pop. 3,838. Near it are more than 5,000 granitic obelisks of druidical origin, which stand perpendicularly in 11 rows parallel to the coast.

CARNATIC, an ancient province of British India on the E. coast of the peninsula. Its limits are ill defined, but it is commonly thought to extend from Cape Comorin to lat. 16° N., and from the coast line to an average of about 80 m. inland. The province is separated into 2 parts by the eastern Ghauts, which run parallel with the coast, and which cause a considerable difference in climate between the table-land and the sea-board; the latter, in dry weather, is the hottest part of India, the thermometer sometimes standing at 130° in the shade. The rivers of the Carnatic are the Pannair, the Palair, the Coleroon, and the Vaigaru. The inhabitants are chiefly Hindoos. The Carnatic includes the cities of Madras and Pondicherry, beside the important towns of Arcot, Madura, Tanjore, Trichinopoly, Nellore, and Vellore. It was formerly included in the dominions of the nabob of Arcot, and the contentions arising from a disputed succession first brought the French and English into collision, and ended by the subjugation of the Carnatic under the British influence, which was completely effected in 1801, when the reigning nabob Azim ul Omrah transferred it to the East India company on condition of receiving a pension equal to

1/3 of the revenue, and of his chief officials being provided for. The Carnatic has as one of the wealthy provinces been the cause of endless native warfare and bloodshed, by which, whoever was victor, the unhappy cultivator suffered in the end; as each successive ruler, feeling his tenure uncertain, only cared to make revenue while the power lasted, an example which was but too closely imitated by his unscrupulous ministers and officials. The Carnatic is now included within the administration of the presidency of Madras. The principal occupation of the inhabitants is agriculture, the land being held either by Brahmins who cultivate it by hired labor, or by the farmer himself. Rice is the chief production, of which 2 crops are taken off the same ground in the year, if the facilities of irrigation admit it. Cotton is grown in favorable situations, and upon the high land in the interior of the province millet, sugar, and indigo are raised.

CARNEADES, a Greek philosopher of the sceptic school, considered as the founder of the so-called 8d academy, born at Cyrene, 217 B. C., died at the age of 85 or 90. Of the incidents of his life very little is known, but of his brilliant qualities as a philosopher and a rhetorician, there is abundant testimony in the works of classic authors. In Athens, at that time the metropolis of art and science, he became a student of the stoic and sceptic doctrines, especially those of Chrysippus, of whom he afterward became the most formidable opponent. He had essentially a critical mind, powerful in analysis, but weak in synthesis. While Chrysippus taught the absolute identity of human reason and the intellectual power pervading the universe, thus constructing a philosophical system which bears a strong resemblance to modern pantheism, Carneades hastened to destroy all illusions on the superhuman nature of the soul, and maintained the absolute acatalepsy, or absolute incapability of the mind to comprehend any subject beyond its own human sphere. So direct was his antagonism to the doctrines of Chrysippus, that he is said to have remarked: "Without Chrysippus there would be no Carneades." Whether it be true or not, that whenever he ventured into a philosophical debate with Chrysippus, he took a dose of hellebore to stimulate his mental faculties, his eloquence was considered so irresistible, his logic so forcible, that more than a century later Cicero said: "Him I would not care to challenge in debate, but would rather propitiate him, and implore his silence." Pierre Bayle called Carneades a destroying angel in philosophy, and said that his eloquence melted every thing like wax. One fact is related showing, indeed, that in some instances the eloquence of Carneades was dreaded like something dæmoniacal. In 162 B. C., when he had been sent to Rome as one of 3 commissioners of the Athenian commonwealth, he undertook to give the Roman barbarians a sample of his dialectic powers. He, therefore, one day made a speech in favor of

and the next day one in opposition. Arguments on either side were so convincing, seemingly unanswerable, that the senate became afraid lest the public mind be corrupted by such an exhibition of the arguments for immorality and injustice as well as for morality and justice. In order to get rid of the dangerous example, insisted upon a speedy settlement of the oratorical business for which Carneades had come to Rome. In his blunt rectitude, Cato was unable to comprehend that excessive ment-

ment to which the Greek philosophers attained, and which enabled them to handle the sublimest conceptions of the soul as so intellectual toys. In private life Carneades is to have been very respectable, according to the moral standard of his age. The character of his philosophy, as compared with the abstract metaphysical theories of his adversaries, would seem, however, to point to more of a propensity. That he was an active man, appears from the fact of his having been a diplomatic agent of a country in which the closest attention to public affairs was the road to public office. He enjoyed life, and that singular sublimity of sentiment led some of his stoic opponents to commit suicide in order to dissolve their individuality into that of the universe. When he was at the stoic Antipater had taken poison, he exclaimed: "Has he, indeed? Why, then, let me that I too take—" His friends started at Carneades, after a short pause, added, with a cheerful smile; "... that I, too, take a glass of wine." Still the enjoyment of life lessened his philosophical zeal. It is said that he was frequently so absorbed in his meditation that he forgot to take his meals. He was not an author, so at least says Plutarch; but he transmitted his doctrines to his disciples by word of mouth, like Socrates. It is said that Machus of Carthage, one of his disciples, owed the preservation of his life in writing his doctrines.—So far as the philosophy of Carneades is known by the statement of Sextus Empiricus, its substance may be condensed as follows: Every perception is a certain change or impression in a sensible being, bringing to consciousness first itself, and secondly some object. In respect to the object, the perception is either true or false; in respect to the subject who perceives, either probable or improbable. There exists no test (criterion) to determine on the truth or untruth of a perception, or, to say, on the relation which the perception bears to the object by which it is determined.

There is no objective certainty, or any other that real existing things are essentially determined by the human perception. Hence the sceptical assertion, whether affirmative or negative, is justifiable. Nay, this very assertion that there is no certainty, does not convey any other truth. But whatever the relation of human perception to reality, to man himself the mere perception is the test of which lies within the

limits of his mind, is sufficient for all practical purposes. The probability of a perception stands in proportion to the closeness with which it corresponds to a chain of other perceptions previously tested and sifted.—Thus much may be designated as the affirmative or dogmatical portion of the philosophy of Carneades; the practical portion was his criticism of the then existing philosophical systems. The force of these criticisms, which was estimated so very highly by his contemporaries, is based merely upon the supposition, not contested at that time, that the affirmations and negations of human language comprise all existing possibilities, so that if both should be refuted, a *non est* would be proven. A simple "either—or" is the whole working capital of this method of reasoning, which constituted the glory of the sophists of old. Thus, for instance, Carneades pretends to prove the non-existence of God by the following strain of reasoning: God is either a rational and sensitive being, or he is not. If he is, then he would be subject to sensations agreeable and disagreeable, to likes and dislikes; but if so, he would be a changeable being, and, as such, liable to destruction. On the other hand, if God is not a rational and sensitive being, then he could not have been the creator of reason and sensation. Again: God is either finite or infinite. If the latter, then he would be motionless, and therefore inactive; if the former, there would be something that was more than he, because limiting him. Again: God cannot be either with or without virtue. If he be without virtue, he would be wicked; but if he had virtue, he would be human, because virtue has existence only as the opposite of sin, and could not, therefore, be a property of a being in which such a contrast is out of the question.—By similar arguments Carneades gets rid of all general ideas of morality, human rights, duties, &c. But when he seems to have destroyed every thing, he suddenly turns round, concluding that all these arguments prove merely that absolute metaphysical knowledge is as unnecessary as it is impossible—that man ought to be satisfied with probabilities and expediences, which are amply sufficient to secure his well-being. Thus, after all, the net result of his scepticism, which in his time terrified so many grave philosophers, is but a snug little piece of practical business philosophy, a self-complacent smile at the fruitless efforts of those who are striving to solve the deep enigmas of divinity and humanity, or persuading themselves that they have succeeded in doing so.

**CARNEIA** (Gr. *Karneia*), a national festival of the ancient Spartans, celebrated in honor of Apollo, and in the Spartan month Carneia. The festival lasted 9 days, during which the Spartans were not allowed to enter upon a hostile campaign.

**CARNELIAN** (Lat. *cornis*, flesh), one of the numerous varieties of the quartz family of minerals. (See *AGATE*.) It is found resembling

flesh in its colors, whence its name. By exposure to the sun and baking, the colors are deepened. Together with agates, carnelians are quarried in great quantities in different parts of Hindostan, particularly in the region of Cambay, whence the name commonly applied to them all of Cambay stones. They are also brought to the lapidary workshops at this place from different parts of Guzerat, to be worked up into round and flat necklaces, beads, bracelets, armlets, seals, marbles, chess men, studs, rings, &c., which make the most important commercial item next to cloth, and give employment in their manufacture to nearly 2,000 people, in 75 large and 25 small workshops. The information relating to the quarrying and working the stones is from the accounts sent on from India with the specimens for the great exhibition in London in 1851. Between the Bowa Gore and Bowa Abbas hills, on the plain, are small mounds, in which the stones are quarried by the Bheels of the district. They sink shafts, and excavate horizontal galleries, working underground with lamps. The stones, being brought to the surface and sorted, are purchased of the miners in the village of Rutunpoor, by the contractor or his agents. When a considerable quantity is collected, a trench is dug in a field 2 feet in depth and 3 in breadth. In this a fire is made with the dung of goats and cows, and upon it earthen pots containing the stones are placed in rows. The fire is kept up from sunset to sunrise, when the chatties are removed, and the stones piled away. These once a year are carted to Nemodra, then sent down the river in canoes to Baroach, and thence in boats to Cambay. The manufacture of beads from the rough stone is thus conducted: The stones, brought to a convenient size, are chipped into a rounded form upon the point of an iron, standing inclined in the ground. Another workman then takes them, and fixing a number of equal size in wooden or bamboo clamps, rubs them on a coarse, hard polishing stone; they are then transferred to another man, who secures them in clamps, and rubs them on all their sides against a ground polishing board, smeared with a composition of emery and lac. The final polish is given by putting several hundreds or thousands of the beads into a stout leathern bag, about 2 feet long and 10 or 12 inches in diameter, with some emery dust and the carnelian powder obtained in boring the holes through the beads. The mouth of the bag is tied up, and a flat thong is bound around its centre. Two men seated at opposite ends of a room then roll it back and forth between them, keeping up the operation from 10 to 15 days, the bag being kept moistened with water. When the beads are well polished, they are passed to the workmen who bore the holes. This is done by means of a steel drill tipped with a small diamond, the work being kept wet by water dripping upon it.—Carnelian is a common mineral in many localities in the United States; but inasmuch as the working of

rough stones is not practised in this country, they are not regarded as of any value.

**CARNICOBAR**, the northernmost of the Nicobar islands, in the bay of Bengal. It is about 40 m. in circumference, low, densely wooded, and very fertile. A settlement was formed here by the Danes in 1760, but was soon abandoned, on account of the unhealthiness of the climate.

**CARNIOLA** (Ger. *Krain*), a duchy of Austria, in the government of Laybach, kingdom of Illyria, between lat.  $45^{\circ} 10'$  and  $46^{\circ} 20'$  N., long.  $13^{\circ} 50'$  and  $16^{\circ} 25'$  E.; bounded N. by Carinthia, E. by Styria and Croatia, S. by Croatia and the district called Hungarian Littoral or Küstenland, W. by the circle of Goertz; area, 3,845 sq. m.; pop. 505,884, the bulk of whom belong to the Slavic races. It is a mountainous region, traversed by branches of the Carniolan Alps, abounding in curious grottoes, caverns, and underground passages, and presenting many snow-capped summits, several of which are about 10,000 feet high. It is neither so well watered nor so fertile as the neighboring districts of the empire, the only river of note being the Kulpa, and the lakes being mostly very small. The southern part produces fruits and a fine variety of flax; bees and silkworms are extensively reared, and in some districts, wheat, barley, and the grape are largely cultivated. With minerals, Carniola is richly gifted. Its famous quicksilver mines at Idria once produced upward of 16,000 cwt. per annum, and still yield from 3,800 to 3,500 cwt. Iron, lead, coal, marble, clays, and precious stones are also found. There are manufactures of iron, steel, fine linen, woollen, flannel, worsted stockings, lace, leather, wooden ware, &c. The exports comprise several of the above articles, together with hats, glass, wax, wine, and flour; and the imports, salt, oil, coffee, sugar, tobacco, cloths, cattle, and fruit. The inhabitants are temperate and industrious. The Lutheran reformation made great progress here at first, but was checked by vigorous efforts, and Roman Catholicism is now the predominant religion.—Carniola was subdued by the Romans at an early period, and was occupied by a Slavic tribe in the 6th century. It was Christianized in the 8th century, became a margraviate under the successors of Charlemagne, was governed alternately by the dukes of Austria and Carinthia, and in the 12th century was erected into a duchy. It was then held by the powerful dukes of Tyrol, until the extinction of that family in 1335, when it passed into the hands of the counts of Goertz, who were succeeded by the house of Austria in 1365. By the treaty of Vienna in 1809, it was ceded to France, and incorporated in the kingdom of Illyria; but restored to Austria in 1814. Carniola has been divided since 1849 into 10 districts. Laybach is the capital, and the Carniolan diet, composed of 82 members, assembles there.

**CARNIVAL**, a festival observed in most Roman Catholic countries immediately be-

the commencement of Lent, but celebrated more parade in Rome and Venice than any cities. Its name is doubtless derived from Latin, *carni vale*, farewell to meat, as from Wednesday, the 1st day of Lent, a strict fast was observed for 40 days. Much dispute exists as to the origin of this festival, but it has probably come down from the Saturnalia of pagan Rome, modified by the early Christians into a fast during the several days preceding the Lent of 40 days, generally supposed to have been instituted by Telesphorus, bishop of Rome, about the middle of the 2d century. The carnival has been observed with more or less enthusiasm during the course of centuries in kingdoms over which the Roman church has held principal sway, but it appears to be most peculiarly adapted to the genius of the Italian people, being followed by them with undying spirit, while in other lands it has frequently languished or fallen into utter neglect. The only relic of it remaining in England, or ever introduced into the English colonies of North America, consists in the observance of Shrove Tuesday. In Paris the carnival takes place during the 5 or 6 weeks preceding Ash Wednesday, and is marked by the giving of masked and fancy balls in private houses and at the various places of public amusement; such balls, to which the public is freely admitted, having been first permitted by the regent duke of Orleans in 1715. During the festivities, masks appear in the streets only on the Sunday, Monday, and Tuesday preceding Lent, and at Mi-Carême or mid-Lent Thursday. On these days a number of persons in disguise, many of them masked, and exhibiting all sorts of folly, parade the streets, principally the northern Boulevards, and immerse the crowds in carriages, on horseback, or on foot. They assemble to witness the gayeties of the carnival. The carnival was prohibited in 1790, and no more celebrated until the appointment of Napoleon Bonaparte as first consul. Its restoration was a cause of great joy to the Parisians, and for some years nothing could exceed the beauty and richness of the costumes displayed upon this annual festival; but it has now lost many of its charms, and the masks are comparatively few. After parading the streets, the masks repair for the night to the various masked balls of every description, which then abound in the capital. The public masked balls take place on fixed days throughout the carnival, being given at almost all the theatres; the most important being at the opera houses, where they commence at midnight and are kept up until daybreak. A motley throng of jaded maskers of both sexes may then be seen for an hour or so about the Boulevards, and swarming in the streets to breakfast. Citizens and strangers have the privilege of going to these balls in plain clothes and unmasked, although the ladies generally appear with masks and fancy costumes.—The procession of the *bœuf gras* (the fat ox) has of late years past been celebrated at Paris, on the Monday and Tuesday before Lent, when the gov-

ernment prize ox, preceded by music, and accompanied by a numerous train of butchers fantastically dressed, is led through the streets. The ox is covered with tapestry, and his head adorned with laurel. Formerly the ox bore on his back a child, called *roi des bouchers* (king of the butchers), decorated with a blue scarf, and holding a sceptre in the one hand and a sword in the other. He now follows the ox in a triumphal car, but without his sword and sceptre.—The carnival in Italy is much the same in the different cities where it is celebrated; that of Venice is by no means as brilliant as in former days, and it will be therefore sufficient to describe that of Rome. It extends over the 11 days which immediately precede Ash Wednesday, though only 8 days are actually given up to its festivities, the 2 Sundays and Friday not being included, from motives of religion. The festivities are held in the Corso, and the street immediately adjoining, to which the show is confined. The Corso is about a mile long, but very narrow, being on an average only about 85 feet broad, and lined by lofty houses, nearly all of which are built with overhanging balconies, with especial reference to this spectacle; and where permanent balconies are wanting, temporary structures of wood are frequently erected. Thus persons on opposite balconies are brought within speaking distance, or near enough to exchange bouquets and sugar-plums. The street beneath is densely filled with carriages and foot passengers, and all are brought so close together as to act and react upon each other. The sport does not last through the whole of each day, but only from about 2 o'clock until dark, during the short days of February. If the weather is favorable, as much of the exhilaration of the scene depends upon sunshine, a stranger will on first beholding the carnival become madly excited and fully enter into its spirit in spite of himself, solemn as his deportment may usually be. The dull and sombre fronts of the houses seem suddenly to have put on liveries of blooming colors. Pieces of brilliant cotton, cloth, or silk, red, yellow, and blue, are hung over the balconies, while innumerable streamers of the same hues flutter in the breeze. Far as the eye can reach, the balconies are crowded with innumerable spectators, many of them beautiful and gayly dressed women. The course below is thronged with 2 rows of carriages, moving in opposite directions and filled with gay parties; while crowds of pedestrians mingle among the vehicles, who, clad in every variety of costume that ludicrous fancy can suggest, and masked, play every imaginable prank within the bounds of decency. A dozen masks will sometimes gather together on the back of a carriage, regardless of the occupants, vociferating in a leash of languages, and one and all in the street or on the balconies engage with heart and soul in pelting others far and near with flowers, bonbons, and confetti. For some time before the carnival begins flowers are brought into Rome in exhaustless profusion, and exposed for sale in

such quantity and choice as to meet the caliber of every purse; costly bouquets of hot-house flowers being ranged side by side with the wild growth of the Campagna. The bonbons are not so abundant, but still are used extensively; while the confetti, which are nothing but pellets of lime about the size of a pea, are scattered in myriads, and form quite a serious weapon of attack, especially if suddenly dashed into the face as they often are from the hand, or blown out of a tin tube. The coating flies off these confetti into lime dust, with which persons become so covered from head to foot as to resemble millers. A few years since, a young English nobleman, noted for his eccentricity and senseless prodigality with his money, was in Rome during the carnival. Hiring an apartment on the Corso, he literally choked it with bonbons and confetti, and for a single feat, filling a large barrel with these missiles, aided by his servant, he dragged it into the balcony, tipped it upon the balustrade, and watching his opportunity showered down the whole of its contents into a passing carriage. The confectionery and lime pills fell with such force, that they started a panel in the bottom of the vehicle, filled it completely, beside nearly smothering the occupants, and scaring them out of their wits by the unexpected avalanche. A complaint was entered against him, and his fun suddenly stopped by a notice from the police, that if he played such antics again, he would be obliged to quit Rome. Every day of the masquerade the Corso becomes more crowded and more animated, till on the last the number and spirit of the masks, the skirmishes of bonbons and lime dust, and the shouts and enthusiasm of all, surpass description. Of the mass which elbow one another through the crowded streets, the greater part are in their ordinary garb, though disguises are common enough not to attract any particular notice. Among the most usual masks are punchinellos with enormous noses, and protuberant backs and stomachs; harlequins in particolored vestments, with daggers of lath; and pantaloons indulging their usual propensity for thieving by snatching bouquets from the hands of those in passing carriages. Quack doctors are numerous, with catalogues of nostrums for all imaginable diseases, and lawyers in gowns and wigs whose demeanor Portia could scarce excel. Some of the masks carry an inflated bladder on the end of a stick, with which they deal noisy but harmless blows. Beside the carriages such as are seen every day, many are put together for the occasion merely, and consist of frame-work resting upon wheels, and made to assume various shapes, such as ships or moving forests. Old dwellers in Rome compare the insignificance of the present carnival with its splendor in the past, and tell of pageants representing eastern monarchs followed by their trains of African slaves; cars of victory with laurel-crowned Cæsars; Roman processions copied from those of the ancient city; the triumph of Bacchus, surrounded by Silenus and all his crew of

drunken fauns and delirious Bacchantes, which used to parade the Corso.—Every day of the masquerade there is a race by spirited horses, but without riders. About 5 o'clock preparations begin for the running of these animals. Mounted dragoons trot up and down the Corso, the carriages are withdrawn into by-streets, and pedestrians alone are left. Meanwhile the horses which are to run have been brought to the starting-point in the Piazza del Popolo. Each one is held by his groom in a showy uniform, and they are kept within bounds until the hour for starting arrives, by a rope stretched across the Corso. So impatient are the animals, however, so fully excited by the tumult of the scene, that it is almost impossible to prevent them from leaping over the rope and dashing onward, while in their struggles they do frequently get their fore feet over, dragging their grooms after them. The horses, as before observed, have no riders, but are goaded on in the race by metal balls full of sharp points, which are fastened to their trappings, and at every motion pierce their flesh; as they feel these irritants they dash madly forward, and the faster they run the more cruelly are they goaded. Instances have occurred in which horses, discovering the cause of their torment, have stopped short in the race, but generally as soon as the cable is thrown down they rush with fury through the Corso, the crowd opening to give them a passage and closing up behind them, until they are stopped by a piece of cloth which is suspended across the street near the Venetian palace, at the Ripresa di Barberi, so called from Barbary horses being the original racers. At this point the judges are assembled to decide upon the race. Goëthe, who visited Rome in 1788, says that carriages were then allowed to remain in the Corso, and their presence rendered it so narrow that horses often dashed themselves against the wheels and were instantly killed.—Speaking of these horses, Madame de Staël, in her "Corinne," says: "They arrive with neither bridle nor saddle, their backs only covered with brilliant stuffs, and conducted by gayly dressed grooms, who manifest the most impassioned interest in their success. They place the steeds behind the barrier, and their impatience to be free is excessive. This ardor of the horses, the cries of the grooms, make at the instant of the barrier's fall a real dramatic act. The horses dash forward, the grooms cry 'Room! room!' with indescribable transport. They accompany their steeds with gesture and voice as long as they can see them. The horses are as jealous of each other as the men. The pavement flashes fire beneath their hoofs, their manes stream upon the wind, and their desire to gain the prize, thus left to themselves, is so great that some on arrival at the goal drop dead from the fury of the race. One is astonished to see these loose horses thus animated by personal passions. They reach the Venetian palace, and it is worth while to listen to the exclamations of the

over the conquering horses. He for the first prize had been gained, went on his knees before his horse, thanked him, invoked on him the blessings of St. George, the patron of animals. It is general custom of day that the races are concluded, and begins another kind of amusement, a masque but very obstreperous. The lights are illuminated. The guards abandon their posts to mingle themselves in the general confusion. Each one then produces a little taper, and seeks to extinguish those of his rivals, while at the same time preserve his own, while repeating changes on the word of command with amazing velocity. *Che la bella principessa sia ammazzata! Che il signore sia ammazzato!* (meaning literally, kill the beautiful princess! kill the signor). The crowd is now assured of safety, and no carriages are allowed, and finally the uproar up to dissonant tumult. Meanwhile the dances, the noise ceases by degrees, and the profoundest silence succeeds, and of nothing there remains only the idea of a dream which has changed every one's mind, which for a moment has caused them to forget their toils, the learned their studies, and the nobles their idleness."

**CARNIVORA** (Lat. *carnis*, flesh, and *voro*, to devour), an order of mammals which feed on flesh, as distinguished from the *herbivora*, or plant-feeders. This order has been divided into various groups by different authors, including in it the *cheiroptera* and insectivores, and others limiting it to the following five families, which agree in their most essential characters, viz.: *ursida*, or bears; *mustelida*, or weasels; *canida*, or dogs; *felida*, or cats; *phocida*, or seals; the bears constituting the *digitigrades*, the seals the *pinnigrades*, and the weasels and cats three the *digitigrades*, according as the whole foot or only the toes touch the ground, as the extremities are modified into claws or paws. The *felida* are the most truly carnivorous, and constitute the type of the order, in them the large canine teeth, sharp claws, great strength and agility, in special formation for the pursuit and capture of living prey. The skeleton exhibits modifications adapted for the manner of life, the shape of the bones, their articulations, proportions. In the *felida* the spine is short, yet strong, with a large development of the thoracic portion; the ribs are narrow and the limbs long and affording the greatest freedom of motion, and the skull is large and broad. In the weasels, the spine is long and in accordance with the habits of burrowing creatures. In the bears, the foot is large and placed on the ground, and the short-lumbar region of the spine adds to the mass and strength of limb required in the carnivorous animals. In the seals, the limbs are extended backward into 2 pairs of flippers, the anterior also serving in ad-

dition for a limited progression on land. The cranium is remarkable for the shortness and strength of its facial or tooth-bearing portion, and for the crests and large fossæ for the accommodation of the powerful muscles of mastication; in the cats, the tentorium cerebelli is bony, evidently to protect the brain during the sudden movements of leaping upon their prey, and the whole bony structure is remarkably solid; the lower jaw is strong and short in proportion to the carnivorous propensity of the genus. The vertebrae of the neck are remarkable for the size of the first 2; the dorsals and the number of ribs vary from 13 (the most common) to 16; the lumbar vertebrae, always numerous in proportion to the leaping powers, vary from 4 to 7; the sacrum is composed of several vertebrae, and in the bears is remarkably broad, for the support of the body in their frequently erect position; the tail is the longest in the most active species, as in the lion and the panther. The shoulder blade is flat and broad; the clavicle, when not entirely wanting, is quite rudimentary; the humerus is arched, short, and strong; the bones of the forearm have but little motion on each other, except in the *ursida*, and the ulna is generally placed behind the radius, both of them in the seals being broad and flat: the metacarpus is much larger in the *digitigrades* than in the *plantigrades*. The retractile claws of the *felida* are described under the article CAT, in which family they are most developed. The pelvis is short, and its bones broad and flat; the thigh-bone is moderately long, and directed immediately downward, except in the seals, in which its direction is outward. The bones of the leg are generally separate; the tarsus consists of the usual 5 bones, but the tuberosity of the os calcis is quite long and strong; the inner metatarsal bone in the cats and dogs is merely rudimentary; in the weasels the inner toe is small, in the cats wanting, and in the *plantigrades* in the same range as the others; in the *plantigrade* foot every thing is arranged for slow and steady walking, in the *digitigrade* for leaping and tearing, and in the *pinnigrade* for swimming. The muscles in this order, especially of the jaws, neck, and anterior extremities, are enormously large and powerful. In the typical carnivora, the incisor teeth are small, and placed in the intermaxillary bone; the canines situated above, at the junction of the intermaxillaries with the superior maxillaries, are strong, long, and cutting, slightly curved, and admirably adapted for tearing their prey; the cheek teeth have cutting edges, the lower shutting within the upper like the blades of scissors, and are provided with sharp triangular processes; the teeth are arranged in a short space, and their action is rendered more efficacious by the shortness of the whole jaw, and by the simple, hinge-like motion of the lower jaw; in the seals, the canines are much smaller, but the cheek teeth are furnished with numerous sharp points for the purpose of holding the slip-

pery and scaly fish upon which they feed; in the bears, the jaws are much longer, and the molars are flattened and tubercular, indicating the far less carnivorous propensities of this family. The carnivora, in proportion to their approach to the typical *felidæ*, whose food, when swallowed, is so like their own tissues that it is ready for speedy assimilation, have a short intestinal canal; in the lion it is but 8 times the length of the body, and has very few internal folds, and a very small cæcum, while in man it is 5 times as long, in the horse 10 times, in the sheep 28 times; such is the relation between the organs, that the form of the teeth indicates the character of the intestinal canal, the armature of the feet, the mode of progression, and very nearly the habits and mode of life of an animal. The lobes of the liver vary in number from 4 in the badger to 8 in the lynx, without any apparent physiological reason; the hepatic ducts correspond in number to the lobes, and the common duct, before it enters the intestinal cavity, frequently receives a pancreatic duct; the gall-bladder is always present, and in the *ursidæ* is of great size; the pancreas and spleen do not differ, except in form, from these organs in other mammals; the chyle is so noted for its opacity and whiteness, that the discovery of the lacteals was made in these animals long before they were seen in man. The carnivora belong to the sub-class *gyrencephala* of Owen, in which the cerebral hemispheres are the largest developed (except in man), extending over a portion of the cerebellum and the olfactory lobes; in this arrangement they are next to the *quadrumana*, or monkeys; the hemispheres have well-marked, though simple convolutions. The organs of sense are well developed; in the diurnal carnivora, the pupil is round; in the cats it is elongated vertically, and in a very bright light almost linear, but it is round in the dark, causing the brilliant *tape-tum* of the posterior arch of the choroid to appear like a ball of fire; the large size of the mastoid process, communicating with the cavity of the tympanum, indicates considerable acuteness of the sense of hearing, necessary for animals seeking their prey during the stillness of night; the sense of smell, especially in the *canidæ*, is very acute, and the pituitary membrane is extended greatly by means of the complicated convolutions of the turbinated bones; the sense of taste is probably not very acute, and the tongue of the cats is covered in its middle portion with horny spines, well calculated to tear the flesh from bones. The kidneys in some families, as in the bears and seals, are much subdivided, resembling a bunch of grapes; in the cats the divisions are hardly perceptible. In the civets and allied genera, there are glandular follicles, which secrete a peculiar odorous substance, sometimes exceedingly fetid; the glands are usually situated near the anus, and the excretory ducts open between the rectum and the genital organs. The *testes* are generally pendulous and external, but in the seals they

remain permanently within the abdominal cavity; the *testicula seminales* do not exist, but organs resembling the prostate and Cowper's glands are generally found; in almost all there is a bone in the penis, the hyena forming an exception, it is said; the teats are abdominal, ranging from 4 in the lioness to 10 in the bitch; the placenta is zonular, surrounding the fetus.—The geographical distribution of the carnivora is very extensive, but the largest and most destructive species are confined to the tropics of the old world; the tiger is limited to Asia, the lion to Asia and Africa, the cougar to America; the largest bears frequent the arctic regions, and the largest seals the antarctic waters. The carnivora fulfil an important purpose in the economy of nature, by keeping in check the increase of the herbivorous animals, whose countless numbers would otherwise destroy vegetation, and thus cause their own and a general destruction. Cuvier associated, under the name *carnassiers*, the cheiroptera, insectivora, carnivora, and marsupials; excluding the latter, which form a sub-class by themselves, many more recent authors adopt a somewhat similar classification. Prof. Agassiz, in his recent "Essay on Classification," divides mammals into 3 orders, *marsupialia*, *herbivora*, and *carnivora*, the last the highest in the scale. Prof. Owen divides his sub-class *gyrencephala* into the 3 primary divisions of *mutilata* (including the cetaceans), *ungulata* (pachyderms and ruminants), and *unguiculata* (carnivora and the monkeys); the last being the highest in development; in the *unguiculata*, the sense of touch is more highly developed through the greater number and mobility of the digits, and the smaller extent of covering with horny matter; in the carnivora, he places the digitigrades at the head, then the plantigrades, and lastly, the pinnigrades; and among the digitigrades the *felidæ* are placed highest, whose retractile claws and long and narrow hind foot make them the most perfect and typical form of the carnivora.

CARNOCHAN, JOHN MURRAY, an American surgeon, born in Savannah, Ga., in 1817, descended on the mother's side from Gen. Putnam, celebrated in the war of independence. He was yet a boy when he was removed to Edinburgh, the capital of his father's native land. After graduating in the high school and university of that city, he returned to the United States, and entered the office of Dr. Valentine Mott, of New York, as a student of medicine. After taking his degree, he again visited Europe, and passed several years in attendance upon the clinical lectures of Paris, London, and Edinburgh. In 1847 he fixed his residence in New York, and commenced the practice of the profession, in which numerous brilliant and original achievements have gained for him an honorable name, both at home and abroad. In 1851 he was appointed surgeon-in-chief of the New York state emigrant hospital, a station he still holds. In 1853 he successfully treated a case of *elephantiasis Arabum* by ligature of the femoral artery. In

year, he performed the operation of removing the entire lower jaw, with disarticulation of both condyles. In 1854 he excised the ulna, saving the arm, with its function impaired; and subsequently, in another operation, he removed the entire radius, with equal success.

In 1856 he performed, for the first time, one of the most startling and original operations on record, in excising, for neuralgia, the trunk of the 2d branch of the 5th pair of nerves from the infra-orbital foramen, as if it were a *foramen rotundum* at the base of the skull. In amputation at the hip-joint he has performed the operation 4 times. Since 1851, Dr. Carnochan has been professor of the principles and operations of surgery in the New York medical college, and has published his lectures on paralytic affections of the foot, lithotomy, and lithotrity, and also a "Treatise on Congenital Dislocations" (New York, 1850); "Contributions to Plastic Surgery" (Philadelphia); and has translated Sedillot's *Traité de médecine opératoire*, and Karl Rokitansky's *Handbuch der pathologischen Anatomie* into English.

CARNOT, LAZARE NICOLAS MARGUERITE, a statesman and tactician, born May 18, 1753, Nolay, Burgundy, died Aug. 2, 1823, Emsburg, Prussia. When only 18 he was appointed lieutenant of engineers; 2 years later promoted to captain, in which rank he wrote an essay on aerial navigation and the works of Vauban, which brought him into contact with Gen. Montalembert, who advised him to be arrested and confined in the Bastille.

He had also published about the same time *Essai sur les machines*, in which he stated a new theorem upon loss of motion, which Arago has declared to be one of the greatest and most useful discoveries of the age. He was entirely absorbed in these studies when the revolution commenced. He did not actively participate in it, although he was elected to the national assembly a member of the committee on finance. In 1793 he was elected deputy to the legislative assembly by the department of Pas de Calais. He devoted himself assiduously to his new duties as a member of the committee on military affairs, he greatly contributed to the adoption of the decree ordering a large addition of men to the national guard; and it was in connection with his report that, for want of muskets, new guards were armed with pikes.

One of these weapons was soon tried in the assault against the Bastille, 10, 1792, in the assault against the Bastille. About the same time he was re-elected to the convention, and was present on the execution of Louis XVI.; his vote was recorded in the following words: "In my opinion, both justice and policy require the death of Louis; I must confess that never a duty so heavily weighed on my heart as the one that is now incumbent upon me." He was neither a Girondin nor a Montagnard, and however aggrieved at the course of the former party, he did not hesitate to

side with the men to whose hands the destinies of the republic were henceforth committed. In Aug. 1793, he entered the committee of public safety. The armies were disorganized and unruly; there were no funds, no provisions; enemies had invaded France in every direction; the insurgent Vendéans were successful; the rebellious city of Lyons kept at bay the besieging army; and Toulon had been just delivered by treason into the hands of the English. Carnot went boldly to work, and succeeded so well, that his fellow-citizens declared emphatically that he had "organized victory." He proved himself to be not only a skilful administrator, but a tactician of the highest ability. The 14 armies created by the rising *en masse* of the nation, coöperated under his orders in the execution of a well-devised plan; they were placed under the command of new generals able to understand the projects of the directing mind, and defeats were soon succeeded by brilliant victories. Carnot sometimes repaired in person to the weakest or most exposed point to watch the operations, and to inspire the troops with his ardor and confidence. Thus, by the energy and wisdom of his measures, as well as by the influence of his example, he contributed to the victory of Wattignies, which forced the prince of Coburg to retreat. Toulon was now retaken from the English; the Vendéans were defeated and almost destroyed, and the Austrian army was expelled from France. As a member of the committee of public safety, Carnot must bear his part of the responsibility for the bloody measures which were then adopted; but it may be said in his exculpation that, being entirely absorbed in the performance of his especial duties, he had no time to give attention to what was going on around him. He left the interior administration in the hands of his colleagues, and was scarcely aware of the atrocities which were perpetrated in the name of the committee. Thus, he did not participate in the revolution of the 9th Thermidor; but after the fall of Robespierre he energetically defended his colleagues, Collot d'Herbois, Billaut-Varennes, and Barere, charged with being the accomplices of the man in whose overthrow they had been instrumental. Carnot was on the point of being arrested, and was only saved by Bourdon de l'Oise exclaiming: "This is the man who has organized victory." After the 1st Prairial (1795), he was again threatened with impeachment, but was protected by the feelings of respect and gratitude which his great services inspired. He was obliged, however, to leave the committee and give up the management of war affairs, which he had held for nearly 2 years. On the establishment of the directory, he was elected representative by 14 departments at once, and took his seat in the council of 500. Being appointed one of the 5 directors, he resumed his previous office and planned the admirable campaign of 1796, the success of which was secured in Italy by Bonaparte.

parte. But the directory was threatened by factions, and especially by the royalists; 8 of its members concluded that the only means of saving the republican government was a *coup d'état*; they performed it on the 18th Fructidor, and although Carnot was far from being a royalist, he was condemned to transportation. He avoided the sentence by concealing himself for a while in Paris, then escaping to Switzerland, and afterward to Germany, where he wrote a memoir to vindicate his conduct. After the 18th Brumaire he returned to France, and was appointed minister of war in 1800; but being unable to agree with the new master, he promptly resigned. In 1802 he was elected to the tribunate, where he voted against the establishment of the legion of honor, the consulate for life, and especially the empire. The speech he delivered on this last occasion breathed the most generous spirit of independence, and caused a great sensation. On the suppression of the tribunate he retired to private life, and resumed his scientific pursuits. But in Jan. 1814, when disasters were coming on France and the emperor, he addressed a noble letter to Napoleon, proffering his services: "I staid away as long as you were prosperous; now that misfortune has come, I do not hesitate to place at your disposal what little ability I may still possess." Napoleon at once intrusted him with the command of Antwerp. For years the supreme director of military affairs, he had gained no advancement in the army, and was still merely a major; Napoleon had to promote him to the rank of general, passing him through all the intermediate degrees at once. He gloriously defended Antwerp until the treaty of Paris, April, 1814, and returned to the capital, where he published a *Mémoire au roi*, full of liberal opinions and wise advice. On Napoleon's return from Elba, he appointed Carnot minister of the interior, which post he held for 8 months, during which he unwillingly received the title of count of the empire, but never bore it. After the rout of Waterloo he almost alone preserved his self-possession, and suggested energetic measures which were not adopted. "I have known you too late," said Napoleon on his departure. A member of the provisional government, his honesty was not a match for Fouché's shrewdness. On the second restoration he was again outlawed, and retired to Warsaw, then repaired to Magdeburg, where he died. His writings are numerous; beside his various political papers, he has left disquisitions of great interest on several points of science, especially on fortification. A full and excellent biography of Carnot was published by Arago (Paris 1837).—LAZARE HIPPOLYTE, a French statesman, the second son of the preceding, born at St. Omer, April 6, 1801. He was of liberal opinions, became a disciple of St. Simon, and wrote the *Exposition générale de la doctrine Saint Simonienne*, the authorship of which was, with his consent, ascribed to Bazard. But as soon as St. Simonism

assumed the form of a religion, he parted with his friends, and became a journalist, and the chief editor of the *Revue encyclopédique*. He was also intrusted with the editing of Grégoire's and Barère's *Mémoires*. He was elected to the chamber of deputies in 1842 and 1846. At the revolution of Feb. 1848, he was minister of public instruction until July 5, and improved the condition of the teachers, reduced the schools free, and established free lectures. In 1848 he was elected to the chamber of deputies. March 10, 1850 to the chamber of peers. After the *coup d'état* of Dec. 2, 1851, he was excluded from France; during his absence, he was a member of the *corps législatif*, but refused to take the oath. He was re-elected in 1859, but again refused to serve.

CARNUNTUM, an ancient Celtic town in the N. part of Pannonia, on the Danube, near where Hainburg now stands. It was an important military pass under the Romans, who made it at one time a station for their fleet on the Danube, and raised it to the position of a *municipium* according to some inscriptions, of a colony according to others. During the wars with the Marcomanni and Quadi it was for 8 years the residence of Marcus Aurelius, who composed a part of his "Meditations." It was destroyed by the Germans in the 4th century, was afterward rebuilt, became once more a Roman military station, and was finally destroyed during the wars with the Magyars in the middle ages. Its remains are very extensive.

CARO, ANNIBALE, an Italian poet, born at Citta Nuova in 1507, died in 1566. In 1543 he entered the service of Pietro Ludovico Farnese, who 2 years later was made duke of Parma, and who sent him several times on missions to the emperor Charles V. When the duke was assassinated at Piacenza, Caro fled to Parma, where he was kindly received by the new duke, Ottavio Farnese. He then became secretary successively to the 2 brothers of Ottavio, the cardinals Ranuccio and Alessandro. He died while in the service of the latter, having been his secretary for 18 years. His works were not printed till after his death, some of them as late as 1588, and a volume of his letters, edited with notes by Mazzuchelli, in 1829.

CAROL (It. *carola*, a song of joy), originally a song sung as an accompaniment to dancing, but which in England serves to designate a ballad for Christmas.

CAROLAN, TURLOUGH, an Irish musical genius born in the county of Westmeath, in the latter part of the 17th century, died in 1733. Having lost his sight when a child, he studied the harp, and in after life not only maintained himself thereby, but even became famous.

CAROLINA, NORTH, one of the original states of the American union, situated between lat. 33° 53' and 36° 33' N., and long. 75° 35' and 84° 30' W., having an extreme length of 420 m. from E. to W., and an extreme breadth of 180 m. from N. to S.; area about 45,000 sq.

100,000 acres. It is bounded N. by on the line of 36° 33', W. by Ten- by Georgia, South Carolina, and , and E. by the Atlantic. It into 88 counties, as follows: Ala-lexander, Anson, Ashe, Beaufort, aden, Brunswick, Buncombe, Burke, Caldwell, Camden, Carteret, Cas- wba, Chatham, Cherokee, Chowan, l, Columbus, Craven, Cumberland, Davidson, Davie, Duplin, Edgecombe, Franklin, Gaston, Gates, Granville, uilford, Halifax, Haywood, Hender- ord, Hyde, Iredell, Jackson, Johnston, oir, Lincoln, McDowell, Macon, Madi- n, Mecklenburg, Montgomery, Moore, w Hanover, Northampton, Onslow, asquotank, Perquimans, Person, Pitt, dolph, Richmond, Robeson, Rocking- van, Rutherford, Sampson, Stanley, arry, Tyrrel, Union, Wake, Warren, on, Watauga, Wayne, Wilkes, Yadkin, North Carolina has no very populous chief seaport and largest city in the umington (originally called Newton, ed in compliment to the earl of Wil- situated in New Hanover co., on the Cape Fear river, about 35 m. from tic, 148 from Raleigh; pop. in 1850, bably 10,000 now. It is a place of le business activity. Raleigh, the po- tal of the state, named in honor of Sir leigh, is a handsome town, situated in , near the Neuse river; pop. in 18. Newbern, formerly the capital te, is a thriving town, situated at the of the Neuse and Trent rivers, about S. E. from Raleigh, in Craven co. is oldest towns in the state, and is a place rable commercial importance; pop. in 1. Fayetteville is a flourishing and own, situated on the Cape Fear river, ad of steamboat navigation, in Cum- ., about 60 m. S. by W. from Raleigh, active business place; pop. in 1853, aufort is a seaport on Bogue sound, in o., 168 m. from Raleigh, has a spacious harbor, and engages in the coasting . in 1853, 2,000. Charlotte is situated he Sugar and Little Sugar creeks in nining county of Mecklenburg; pop. 2,500. Edenton, the county town in co., at the head of Eden bay, e of considerable shipping; pop. 607. Elizabeth City, the capital of k co., is on the Pasquotank river, ove its confluence with Albemarle d 215 m. N. E. from Raleigh, and ates with Hampton roads by means ismal Swamp canal; pop. in 1853, reenville, the capital of Pitt co., is ; place of 1,150 inhabitants, and is 02 m. E. of Raleigh. Halifax, the Halifax co., beautifully situated on bank of the Roanoke river, 87 m. igh, is a place of considerable trade

in cotton, corn, and lumber. Oxford, the capital of Granville co., 86 m. N. of Raleigh, is a town of considerable business activity; pop. in 1853, 2,500. Salisbury is one of the principal towns in the interior of the state, and one of the oldest; pop. 4,000 to 5,000. Asheville, in Buncombe co., is the principal town west of the mountains; pop. in 1853, 1,000. The other towns worthy of mention, and containing populations ranging from 500 to 1,500, are Elizabethtown, the capital of Bladen co., on Cape Fear river, 99 m. from Raleigh; Greensborough, in Guilford co., named in compliment to Gen. Greene, is a flour- ishing manufacturing town; Lincolnton, Lin- coln co., contains several cotton and paper mills, and iron works; Plymouth, Washington co., on the Roanoke, has a large business in the lumber trade and the building of coasting ves- sels; Smithville, on the Cape Fear river in Brunswick co., has a good harbor, and is a place of considerable trade; Tarborough, on the Tar river, in Edgecombe co.; Washington, in Beaufort co., on the Tar river, near its confluence with Pamlico river, has a con- siderable coasting trade and contains the usual county buildings, and 3 churches.— The population of North Carolina, according to the decennial enumerations from 1790 to 1850 inclusive, has been as follows:

Census.	Whites.	Slaves.	Free Colored.	Total Population.
1790	233,204	100,572	4,975	338,751
1800	337,764	133,296	7,043	478,103
1810	376,410	163,324	10,266	555,500
1820	419,200	205,017	14,612	638,829
1830	472,843	245,601	19,543	737,987
1840	484,370	245,817	22,732	753,419
1850	553,025	233,543	27,463	813,031

The federal representative population (all free persons and  $\frac{3}{4}$  of the slaves) is 753,619. Of the white population in 1850, 273,025 were males, and 280,008 females; 15,851 were less than 1 year of age; under 5 years, 85,652; 5 and under 10, 80,200; 10 and under 15, 78,299; 15 and under 20, 61,955; 20 and under 30, 95,648; 30 and under 40, 61,093; 40 and under 50, 42,237; 50 and under 60, 27,399; 60 and under 70, 15,576; 70 and under 80, 7,241; 80 and under 90, 2,190; 90 and under 100, 351; 100 and upward, 61; unknown, 126. The returns show 389 as deaf and dumb; 379 as blind; 467 insane, and 615 idiotic. Born in the state, 529,483; in other states of the Union 20,784, of whom 10,838 were born in Virginia, 4,420 in South Carolina, and 2,087 in Tennessee; in foreign countries, 2,565; unknown, 196. Of the slaves, 144,581 were males, and 143,967 females, and 164 were over 100 years of age. There are 28,303 slave- holders in the state, of whom 1,204 own each 1 slave; 9,668 own 1 and under 5; 8,129, 5 and under 10; 5,898, 10 and under 20; 2,828, 20 and under 30; 485, 30 and under 100; 76, 100 and under 200; 12, 200 and under 300; 3, 300 and under 500. The number of dwellings oc- cupied by white and free colored was 104,996; number of families, 105,451. The number of deaths in the state during the year 1850 was

Black and other mountains, elsewhere noticed; the Swannanoa gap, a deep pass in the mountains between Morgantown and Asheville; the Catawba Falls near by; the warm springs of Buncombe co., Painted rock, and a curious rock called "the Chimneys," in the same vicinity; the Gingercake rock in Burke co., a curious pile of stone on a rocky eminence, in the form of an inverted pyramid, commanding a fine view of a ravine from 800 to 1,200 feet deep. The mountainous regions of North Carolina, abound in grand and picturesque scenery.—The climate of the state is as varied as its surface and products. In the low country the atmosphere is hot and humid, and in the mountainous region it is cool and dry. In the interior it partakes somewhat of each extreme, according to locality. The mean temperature of Raleigh for the year is 60°.—It will be seen by statistics noticed elsewhere that the people of North Carolina are chiefly occupied in agricultural pursuits, though commerce, manufactures, and mining are carried on to some extent. The most important branch of manufacturing is that of spirits of turpentine, which is produced by distillation from crude turpentine, or the sap of the pine tree, the *pinus palustris*, a long-leaved pine yielding the sap more freely than any other variety of the pine family. There is an immense extent of territory in North Carolina covered by this species of pine, extending from a point near the line of Virginia across the entire state, and indeed beyond the state to the gulf of Mexico, and varying in width from 30 to 80 m. This belt of land is situated between the swampy country along the coast and the hilly region of the interior, and consists mainly of a level, sandy barren, so unproductive that few of the proprietors grow as much grain as they require for their own consumption. Occasionally, however, the ground is undulating, and in some places low and wet, where a mixture of deciduous trees and occasional veins of clay are found. Although the "piny woods," as the natives call the turpentine forests, have been settled by Anglo-Saxons about as long as any portion of the United States, yet the roads are very poor, being the merest openings through the woods, and generally without bridges across the streams. The pine trees which cover this tract are from 8 to 18 inches in diameter, with straight trunks which run up 25 to 30 feet without a limb, at which height their evergreen foliage forms a canopy so dense as to nearly shut out the light of the sky. The turpentine is procured by cutting boxes or pockets in the trees near the ground, with a long, narrow-bladed axe made for the purpose. These boxes hold from 1 to 3 pints, and are formed by giving the axe a downward stroke, the lower lip of the box being horizontal, and the upper arched, while the bottom is from 3 to 4 inches below the lower lip. From 1 to 3 boxes are made in each tree, according to its size. The sap runs only in warm weather. The boxes are cut from November to

March, one man cutting from 50 day. The sap begins to flow free middle of March, and is collected in boxes by means of a peculiar ladle, and put in barrels. The sap soon congeals to close the cellular tissues so that in order to renew the surface must be exposed once in 8 which is done by taking off a thin slice above the box. This hacking proceeds on from year to year, until in some pineries the axe marks are extended up the trunks that ladders are used in the scarifications. When the trees are sufficiently hacked, a large proportion of the sap congeals before reaching the boxes to the trees. This gum is occasionally scraped off and put into barrels, and is known in market as "scrape," being of an inferior quality and worth only half as much as the sap in the boxes, which is called "dip." Large quantities of crude turpentine are sent to the N. and distilled; but the greater portion is distilled in the state by the proprietors of turpentine forests of their own, to whom the small quantity of their product in its crude state is sold. The distilleries used are not essentially different from the ardent spirit stills in common use, having a capacity of from 5 to 20 bbls., and distilling 2 batches a day; i. e. a 20 bbl. still will produce 40 bbls. of sap, producing about 10 bbls. of spirits of turpentine, and 23 bbls. of rosin. When the spirits of turpentine are distilled, the residuum, which has the appearance of molasses, forms the rosin of commerce. This article is not in sufficient demand to warrant land transportation; so that, with the exception of those distilleries near railroads and streams, the rosin runs to waste, and is often found in congealed pools of thousands of barrels. "its appearance," says Olmsted, "is like a beautiful, firm, and glare, varying in color from glistening like polished porphyry." When the rosin is to be saved, it is drawn off by water by which the chips and rubbish in the crude turpentine are separated. The rosin, which is barrelled for market, will not pay for wagon transportation more than 30 miles. The turpentine is valued at from \$2 to \$20 per acre. From 500 to 1,000 trees grow upon an acre, and, on an average, 2,000 boxes, and produce from 12 to 16 bbls. of turpentine, spirits and 8 of rosin. A turpentine tree with ordinary treatment, will last for 20 years. The trees are then felled, cut up, and either charred, in kilns, producing pitch is a concentration obtained by the long-leaved pine is of slow growth, rings on a stump of this variety. 7 inches in diameter, indicating an age of 70 years. The removal of these trees, a bastard pine starts up rapidly, and is of little or no value either as lumber or timber. The labor in the

performed by slaves, whose wages, fed, are about \$120 per annum, with clothing. The turpentine business is as favorable to health and longevity, according to De Bow, is generally very profitable to the proprietors. Exact statistics of the turpentine forests are not given. De Bow, in his "Resources of the State," estimates the annual product of North Carolina at 800,000 bbls., of which about 200,000 are exported to northern ports in a crude condition, the remainder distilled in the state.

The value added to the makers is from \$2,000,000. From 4,000 to 5,000 persons are engaged in the business, and it is estimated that 3 times as many more are mainly employed by the proceeds of the sale of turpentine. There are about 150 stills in the state, at an average, \$1,500 each, and showing a net value of \$225,000 in preparations for turpentine business. The census of 1850 reports 396,983 acres of farming lands in the state, of which 5,453,975 acres were improved, 3,008 unimproved. There were 56,963 plantations in the state, averaging 100 acres each; aggregate cash value \$67,000,000; value of farming implements and machinery, \$3,931,532; average value of farm, \$192; average value of farming implements and machinery, \$69. The average productivity of the state per acre is: wheat, 15 bushels; rye, 15; maize, 17; oats, 10; cotton, 65. Cotton plantations producing 2,827; rice plantations 20,000 lbs. and upward, 25. The rice plantations are principally in Anson, Rich, and other counties along the southern coast. The rice plantations are mainly on the Cape Fear and Chowan rivers, and the lower part of the state. The farms of the state are stocked with 148,693 horses, 221,799 milch cows, 434,402 other cattle, 1,812,813 sheep, and 1,812,813 swine; total live stock, \$17,717,647; of animals slaughtered, \$5,767,866. The wheat produced 2,130,102 bushels; rye, 229,568 bush.; maize, 27,941,051; sweet potatoes, 5,095,709; Irish potatoes, 620,318; buckwheat, 16,704; hay, 145,000 tons; hops, 9,246 lbs.; clover seed, 576 bush.; other grass seeds, 1,275 bush.; butter, 95,921 lbs.; cheese, 95,921 lbs.; peas and beans, 584,252 bush.; produce of market gardens, \$39,462; orchard products, \$34,348; and bees-wax, 512,289 lbs.; home manufactures, \$2,086,522; flaxseed, 38,000 bush.; flax, 593,796 lbs.; hemp, 39 tons; sugar, 27,932 lbs.; molasses, 704 gallons; cotton, 54,545 bales of 400 lbs. each; 5,868 lbs.; tobacco, 11,984,786 lbs.; 1,738 lbs.; silk cocoons, 229 lbs.; 58 gallons; value of household goods \$1,413,242. The census report returns 1 manufacturing and mining establishments, a capital of \$7,252,225, using raw

material valued at \$4,805,465, and employing 12,444 operatives (10,698 males and 1,751 females), whose annual wages were \$1,796,748. The annual product of these establishments was \$9,111,245, yielding 84.60 per cent. profit. Among the manufacturing establishments were 28 cotton factories, with a capital of \$1,058,800, using 18,617 bales of cotton, valued at \$581,903, employing 1,619 operatives (442 males, at \$11 65 per month, and 1,177 females, at \$6,12 per month), and yielding an annual product of \$831,842; 1 woollen manufactory, capital \$18,000, using 30,000 lbs. of wool, valued at \$13,950, employing 30 operatives, and producing annually \$23,750; establishments for iron castings 5, capital \$11,500, value raw material \$8,341, hands 15, product \$12,867; wrought iron establishments 30, capital \$170,609, value of raw material \$50,089, hands employed 280, product \$381,914; whiskey distilleries and breweries 47, capital \$21,930, corn consumed 64,650 bushels, rye 4,700, hands employed 72, whiskey and high wines produced 153,030 gallons; fisheries 76, capital \$235,115, hands 2,267, product \$250,025. The exports for the year ending June 30, 1857, were \$414,206, of which \$389,592 was in American, and \$24,614 in foreign vessels. Imports for the same year, \$231,494, of which \$206,747 was in American, and \$24,748 in foreign vessels. The tonnage cleared in the same year was 38,037 tons, of which 34,401 tons were in American bottoms. Number of vessels cleared, 210, of which 192 were American. Tonnage entered, 20,218, of which 18,366 tons were in American vessels; number of vessels entered 124, of which 118 were American. Twenty-one vessels were built in the state in 1857, of which 19 were schooners and 2 sloops, the total tonnage of which was 1,373.74.—The census of 1850 reports 4 public libraries in the state with 2,500 vols., and 1 school library with 1,500 vols., also 51 newspapers, of which 8 were miscellaneous, 2 neutral, 35 political, and 6 religious; 5 are published tri-weekly, 40 weekly, and 6 semi-monthly; aggregate circulation, 36,839; annual number of copies issued 2,020,564. There are 4 colleges in the state, viz., the university of N. C. at Chapel Hill, the oldest institution of the kind in N. C.; Davidson college (Presbyterian) in Mecklenburg co., Wake Forest (Baptist) in Wake co., and Normal college (Methodist) in Randolph co. The university has an attendance of about 400 students, and the others an average of about 100 each. The university, which is under the control of trustees appointed by the state, is endowed to the amount of \$150,000, and Davidson college about \$300,000. The census for 1850 returns 272 academies and private schools, with 403 teachers, 7,822 pupils, \$15,987 endowment, total annual income \$187,648; 2,657 public schools, with 2,780 teachers and 104,095 pupils. The annual income of the public schools is reported at \$158,564, of which \$1,585 is from endowment, \$42,936 from taxation, \$97,867 from

public funds, and \$16,715 from other sources. There were 215,454 white persons in the state between 5 and 20 years of age, so that less than  $\frac{1}{4}$  the children of the state attended school; 80,423 free adults cannot read and write, of whom 26,239 are white males, 47,327 females, 3,099 free colored males, 3,758 females, and 840 of foreign birth. These figures are from the U. S. census for 1850, since which public education has considerably advanced. A system of common schools was inaugurated in 1840, at which time only 14,347 children were returned as attending primary schools; and including those at colleges and academies, the whole attendance did not exceed 20,000 scholars. In 1853 an efficient general superintendent was appointed, and reappointed in 1855, who is responsible to the legislature and board of literature, consisting of 4 members, of whom the governor is *ex officio* president. From the superintendent's report for the year ending Dec. 31, 1855, it appears that there were 120,000 scholars in the common schools, and about 11,000 in colleges, academies, and private schools. The state is divided into school districts with local directors, the districts in each county being under the direction of a board of county superintendents, who report to the state superintendent. The average length of schools is about 4 months in the year, and the average wages of male teachers \$21 per month, females \$18. The school fund in 1855 amounted to \$1,538,995 46, yielding annually about \$120,000 increased to \$180,000 by sales of lands, taxes, &c., and is distributed among the counties according to their federal population. The counties raise by taxation\* about \$60,000, making the amount annually devoted to public schools \$240,000. On July 1, 1857, the school fund had increased to the nominal value of \$2,156,745 42. —The census of 1850 reports 1,787 churches in the state, viz.: 604 Baptist, 786 Methodist, 151 Presbyterian, 54 Free, 51 Episcopal, 29 Christian, 31 Friends, 16 German Reformed, 49 Lutheran, 7 Moravian, 4 Roman Catholic, 4 Union, and 1 Tunker. The church property of the state is reported at \$905,753, viz.: Baptist, \$205,090; Methodist, \$292,608; Episcopal, \$112,340; Presbyterian, \$172,530; Christian, \$10,575; Free, \$16,860; Friends, \$8,075; German Reformed, \$17,500; Lutheran, \$29,525; Moravian, \$34,000; Roman Catholic, \$5,900; Tunker, \$100; Union, \$650. Total church accommodations, 574,924, viz.: Baptist, 201,797; Methodist, 222,687; Presbyterian, 64,230; Christian, 11,600; Episcopal, 15,245; Free, 14,870; Friends, 13,220; German Reformed, 5,725; Lutheran, 19,750; Moravian, 3,000; Roman Catholic, 1,400; Union, 1,200. —The constitution of the state was formed in Dec. 1776, and modified in 1835, and again in 1857. It provides that every white male citizen, 21 years of age, 1 year a resident of the county, who shall have paid a tax, shall be a qualified voter. The executive department is vested in a governor elected by the people for

a term of 2 years, an advisory council, secretary of state, treasurer, and a superintendent of common chosen by the legislature. The governor be 35 years old, worth \$5,000, and resident of the state for 5 years. The legislature consists of a senate of elected for 2 years, and a house of 120 members for the same term must possess each 300 acres of county from which they are chosen. The legislature meets biennially at Raleigh 2d Monday in November, and amendment of representatives is made every 2 years, that of the commons twice. The federal population, and the senate. The judiciary is vested in a supreme court consisting of a chief justice and two associate judges, holding 3 courts each year, and superior courts, there being 7 circuits. The judges, who hold court twice a year in each county. The judges are all elected by the legislature in joint ballot, also an annual election, the former during good behavior, the latter for 4 years. The supreme court have complete equity jurisdiction. The salary of the supreme court judge and of the superior court, \$1,050 each court (over 12) held on a circuit. A peculiar feature of the constitution is that "no person who shall deny the existence of God, or the truth of the Christian religion, or the divine authority of the Old and New Testaments, or who shall hold religious opinions incompatible with the freedom of the press, or the right of the people to elect their representatives, shall hold any civil office." —The last report on the finances shows a state debt of \$5,209,848, interest of which is \$312,591, and property held by the state amounting to \$274. The receipts and disbursements for 2 years ending Nov. 1, 1856, were a total of \$5,209,848. Receipts of literary fund, \$329,826 35; public fund, \$3,826,112 94; making a total of \$4,211,060 08. The disbursements for the same period were: from literary fund, \$665 59; public fund, \$3,557,931 80, leaving a balance in hand of \$256,456 28. The income of the state from the sale of bonds and loans, from interest, public taxes, taxes on land and attorneys' licenses; and the proceeds of expenditure are, for the executive department, about \$10,000, the judiciary, \$30,000, interest about \$300,000, agricultural societies, \$7,500. The receipts are from entries of vacant land, and railroad dividends, retail license duties; and a portion of its income is for the support of the state.

dumb and blind.—The railroads of the : the North Carolina, extending from ough to Charlotte, 223 m., capital stock \$4,000,000, cost of construction and at \$4,235,000; Raleigh and Gaston, g from Raleigh to Weldon, 97 m., cap- paid in \$973,000, funded and floating 1,000, cost of construction and equip- 1,135,451; Wilmington and Weldon, mington to Weldon, 162 m.; Wilming- Manchester, from Wilmington, N. The vious to this settlement (1584) Raleigh, received from Queen Elizabeth a grant lands as he might discover in America, assessed by any Christian people," sent ll vessels which made the land at ear, and coasting north for a har- dly, early in July, ran into Ocracoke d landed on an island called by the Wococon, where they were hospitably . After slight explorations they be- the name of Virginia upon the region, rned to England with a highly favor- out of the country, which induced the on of 1585. Other colonists were sent Raleigh the same year, and the year fol- who are supposed to have fallen victims ndians; and no further attempts were colonize the country till about the mid- ie 17th century. In 1680 an immense and south of the Chesapeake, designated ana, was granted to Sir Robert Heath; being colonized, the grant was subse- declared forfeited. In 1663 Charles II.

formed out of the same territory the province of Carolina, which he granted to 8 distinguished noblemen of England. This grant was bounded S. by lat. 29° N.; W. by the Pacific ocean; N. by lat. 36° 30'; E. by the Atlantic. The grantees were made joint proprietors and vested with jurisdiction over the colonists. Previous to this grant a few settlements had been made in the N. part of the province, near Albemarle sound, by dissenters from Virginia, and a little colony had been planted near the mouth of Cape Fear river by New Englanders, which was subsequently abandoned. The celebrated John Locke wrote a scheme of government for the whole province, which was nominally its fundamental law for about  $\frac{1}{2}$  of a century, but which was so complicated and cumbersome as never to be completely carried out. Albemarle, the name then given to what now constitutes North Carolina, was augmented by settlement from Virginia, New England, and Bermuda, and William Drummond, one of the settlers, was its first governor, a man who was subsequently executed in Virginia as a rebel. Drummond was succeeded by Samuel Stevens, under whom were enacted the first laws for the colony by an assembly composed of the governor, council, and 12 delegates, the latter chosen by the people, and the former by the proprietors. These laws were liberal, guarding carefully the rights of the settlers, and granting religious liberty to all. Settlements were made at various points, and the executive chair was filled in turn by various men; yet with the bad administration of public affairs, disquiet and turbulence on the part of the colonists, and occasional insurrections, the settlement of the country was very slow. In 1674 the population was about 4,000, and the annual product of tobacco 800,000 lbs. In 1695 John Archdale, a sagacious Quaker, was appointed governor, and succeeded in restoring the country to comparative order and quiet. Considerable settlements were made during his administration, and the export of tar and rice was commenced. Churches were erected and provision made for the support of public worship. In 1705 Thomas Cary was appointed governor, but was removed to give place to Edward Hyde; whereupon Cary, to retain his position, incited a rebellion, and at the head of an armed force, attacked Edenton, but was repulsed, and finally, by the aid of regular troops from Virginia (1711), the rebellion was suppressed. Meanwhile the province was involved in a war with the savages. The Tuscaroras, observing with alarm the encroachments of the whites on their hunting grounds, commenced a war of extermination; but by the assistance of neighboring colonies this tribe was subdued (1713), and finally emigrated to the N., and formed a confederation with the Senecas. Other hostile tribes were also reduced to subjection. In 1717 the number of taxable inhabitants did not exceed 2,000, having gained no more than 600 since 1676, a term of 41 years. In July, 1729, during the administration of Governor Everard, Caro-

lina became a royal government, the king having purchased from the proprietors  $\frac{1}{3}$  of their immense domain for £17,500, to which £5,000 was added for arrears of quitrents; the remaining eighth was retained by Lord Carteret, who surrendered his right of jurisdiction, but not of soil. The country was successively governed with indifferent success by Barrington, Johnston, and Dobbs, till 1765, when it had gained considerable accessions to its population from a colony of Presbyterians from the N. of Ireland, who settled in the N. W. part of the state, a party of Moravians who settled between the Yadkin and Dan rivers, and a party of Highlanders who located near Fayetteville. Tryon was the next governor, and early in his administration the contest between the colonies and the home government on the question of taxation began; when the assembly (1769) declared against the right of Britain to tax North Carolina, while unrepresented in parliament, he dissolved it. During his administration there was a formidable insurrection on the part of a large body of poor uneducated people, who complained of unjust taxation, and finally refused to pay any taxes at all. They called themselves the "regulators." With 1,000 militia he met 8,000 regulators, whom he defeated, near Great Alamance, a tributary of the Haw, in which some 200 were killed. Out of a large number taken prisoners 6 were executed for high treason. After this defeat the insurgents took the oath of allegiance, and shortly thereafter Tryon was succeeded by Josiah Martin, the last royal governor of North Carolina. Disputes soon arose between the governor and the assembly, and the breach was widened by the persistence of England in taxing the colonists without their consent. The governor sided with the crown, as did the regulators, whom he had conciliated. North Carolina sent representatives to the first continental congress, Sept. 1774, and its delegates united in adopting the declaration of colonial rights, which the assembly approved, and that body also appointed delegates to the next congress. An association for the defence of colonial rights was formed in Mecklenburg co., which took such decided ground as (May, 1775) formally to renounce allegiance to the crown, and to declare their independence of the British connection; but this feeling was not general, and counter-combinations were formed to sustain the royal authority. Alarmed at the threatening state of affairs, Governor Martin retired on board a man-of-war in Cape Fear river, July 17, 1775. A convention was held, Aug. 20, which authorized the raising of 3 regiments of troops, subsequently increased to 5, and taken into colonial pay by congress. A proclamation was issued by Gov. Martin from on board ship forbidding their meeting, which the convention denounced as scandalous and scurrilous, and ordered it to be burned by the hangman. The loyalists were quite strong, especially among the regulators and Highlanders. A body of 1,500 loyalists, under McDonald and

McLeod, who had attempted to reach ton, but were met by and Moore, and routed, and 850 prisoners, common men were retained. In April, 1776, the convention authorized their declaration of independence, which took place in the following North Carolina ordered 4 more regiments to be raised, and the Highlanders and regulators to be disarmed. In Dec. 1776, the province adopted a state constitution, and elected Richard Caswell as governor. The colony furnished her quota of men, but, beyond the partisan warfare between the patriots and loyalists was not the scene of military operations till 1780. Encouraged by the success of the British in Georgia, a party of 700 N. C. loyalists marched to join the royal cause at Augusta. In their march they were attacked by a party of patriots from S. O., under Col. Pickens, who routed them, killing their leader, and capturing a number of prisoners, 70 of whom were tried and convicted of treason, and 5 of the most influential actually hanged. In 1780, 2 large parties of loyalists rose in arms, one of which attacked and dispersed by Gen. the other, 800 strong, reached the Oct. 9, 1780, a body of loyalist Gen. Ferguson, were met at Ki by a party of mounted backwoodsmen Shelby and Sevier, and defeated engagement, with the loss of 150 (including Ferguson) and a great number. The survivors (800) surrendered to the patriots, active and obnoxious of whom were kept upon the spot. The only engagement of arms in the colony after this affair, until the conclusion of peace, was the battle of Guilford Court House (March 15, 1781), though much skirmishing was carried on between small parties of loyalists and patriots. The force of Gen. Greene at Guilford consisted of 3,000 men, of whom 1,600 were Continental troops, the remainder mainly undisciplined militia. The British, under Cornwallis, were 2,000 troops, about 2,000 strong; and the engagement was the defeat of the British, though the British loss on the field was up to 1,000 and the American something more. While a large part of the militia returned home. The constitution formed in 1787, was rejected by North Carolina in 1788, but finally adopted in 1791.

CAROLINA, South, one of the southern states of the American Union, lies between lat.  $32^{\circ}$  and  $35^{\circ} 10'$  N., and long.  $78^{\circ} 35'$  and  $83^{\circ} 30'$  W. The state has the form of an irregular triangle or wedge, with the coast line for its base, and Georgia and North Carolina for its converging sides. Its extreme length, from Little River inlet on the E. to Choptank river on the W., is about 240 m., and its greatest breadth, from the mouth of Savannah river

to the North Carolina line on the N., 10 m., including an area stated by Gov. at 30,213 sq. m., or 19,336,320 acres. Bounded on the N. and N. E. by North S. E. by the Atlantic ocean, and S. W. by Savannah river, which separates it from

It is divided into 30 districts, similar to counties in other states, viz.: Abbe-der-son, Barnwell, Beaufort, Charles-ter, Chesterfield, Clarendon, Colleton, Edgefield, Fairfield, Georgetown, Horry, Kershaw, Lancaster, Lau-ington, Marion, Marlborough, New-angeburg, Pickens, Richland, Spartan-ter, Union, Williamsburg and York. n, the chief city of the state, and one of the most important seaports in the southern United States, Columbia, the capital of the state, Beau-georgetown, Hamburg, Camden, Green-ter, Spartanburg, Cheraw, Blackville, Winnsborough, Anderson, Yorkville, &c., are the more prominent towns of South Carolina.—The following table shows the population of the state at the several de-numerations since and including 1790:

	Whites.	Free colored.	Slaves.	Total pop.
1790	140,178	1,801	107,094	249,073
1800	196,255	8,185	146,151	345,591
1810	214,196	4,554	196,865	415,115
1820	237,440	6,826	258,475	502,741
1830	257,863	7,921	315,401	581,185
1840	259,064	8,276	327,088	594,398
1850	274,563	8,960	384,984	668,507

White population in 1850, 137,747 were males and 136,816 females; 6,452 were less than 5 years of age; under 5 years, 41,509; 5 and under 10, 40,577; 10 and under 15, 36,974; 15 and under 20, 30,262; 20 and under 30, 47,307; 30 and under 40, 30,807; 40 and under 50, 20,500; 50 and under 60, 13,673; 60 and under 70, 8,372; 70 and under 80, 3,372; 80 and under 90, 1,117; 90 and under 100, 210; 100 and over, 29; unknown 81. Deaf and dumb, 150; insane, 224; idiotic, 249. In 1850, the state, 253,399; in other of the United States, 12,601, of whom 6,173 were born in North Carolina, and 1,621 in Virginia; foreign countries, 8,508, of whom 2,180 were born in Ireland, 2,180 in Germany, 651 in England, and 651 in Scotland; 55. Of white and free colored there were 137 families, occupying 52,642 dwellings; the slaves, 187,756 were males, and 167 were over 100 years old. Of the free colored, 4,131 were males, and 167 were over 100 years old. In 1850, the state, 25,596, of whom 3,492 were slaves; 1 and under 5, 6,164; 5 and under 10, 6,311; 10 and under 20, 4,955; 20 and under 30, 3,200; 30 and under 40, 2,990; 40 and under 50, 2,382; 50 and under 60, 1,990; 60 and under 70, 1,000 and over, 2. Deaths in the state, 8,046, of whom 5,167 were slaves; (free pop.), 2,005; births, 6,607. The number of the free male population over 15

years of age in 1850 were: commerce, trade, manufactures, mechanic arts, and mining, 18,205, of whom 7,009 were employed in manufacturing establishments; agriculture, 41,802; labor not agricultural, 8,151; sea and river navigation, 846; law, medicine, and divinity, 1,829; other pursuits requiring education, 8,161; government civil service, 872; domestic servants, 149; other occupations, 84; total, 68,549. Paupers in the state, 1,818, of whom 329 were of foreign birth; annual cost of support, \$48,337; convicted of crimes in 1850, 46.—Savannah river, which forms the boundary between South Carolina and Georgia, is formed by the confluence of the Tugaloo and Keowee, which rise in the mountains near the line of N. C., and unite at Anderson, in the N. W. part of S. C., and flowing thence in a S. S. E. direction 450 m., empties into the Atlantic 18 m. below Savannah, near lat. 32° N. and long. 81° W. It is navigable for large vessels to Savannah, and for steamers of 150 tons to Augusta, 230 m., and by means of a canal round the falls at Augusta smaller boats ascend 150 m. further. The other principal rivers are the Great Pedee, the Santee, and the Edisto. The former, which rises in the Blue Ridge, flows N. through North Carolina, where it is called the Yadkin, passes through the E. portion of S. C., and being enlarged by the waters of Lynch's creek and the Black river on the right, and the Little Pedee and Waccamaw on the left, empties into Winyaw bay. It is navigable for steamboats to Cheraw, a distance of about 150 m., above which navigation is obstructed by a fall. The Santee is formed by the junction of the Congaree and Wateree, which by their tributaries rise in the Blue Ridge (W. part of N. C.), flow S., and unite in the central part of S. C.; the stream thus formed, taking the name of the Santee, and flowing about 100 m. in a S. E. direction, reaches the Atlantic by 2 mouths, North and South Santee, a few m. S. W. of Winyaw bay. The principal tributaries of the Congaree are the Saluda and Broad rivers. The Santee is navigable for its entire length, and its tributaries, Wateree and Congaree, by aid of canals, are navigable for small craft nearly to the mountains about 200 or 300 m. from the ocean. The Edisto and Combahee rise in the interior, and flowing S. reach the Atlantic near the southernmost point of the state. These streams are 100 to 240 m. in length, and navigable for very small craft. The state is remarkably well watered, and almost every district abounds in good sites for manufacturing by water power.—The coast-line of South Carolina extends from Little River inlet, in a S. W. direction, to the mouth of the Savannah river, about 200 m. The coast presents numerous inlets, bays, shallow sounds and lagoons, and a few good harbors. Winyaw bay, the easternmost harbor of any note in the state, is 14 m. long, and about 2 m. wide. Georgetown is situated at the head of this bay, to which vessels of light draft ascend. Passing S. W., Bull's bay is next in order, then Charles-

ton harbor, St. Helena sound, and Beaufort harbor, or Port Royal Entrance, beside a number of small inlets. Charleston harbor, where the principal commerce of the state centres, has a difficult sand-bar at its entrance. Beaufort harbor, which admits vessels of 24 feet draught, is one of the best in the southern states. Stone inlet, a few miles S. of Charleston, admits vessels drawing 9 or 10 feet of water, and was resorted to during the blockade of Charleston in 1775. St. Helena sound, is a spacious opening 10 m. long and 3 broad. A number of small islands skirt the S. coast of the state, which are shut off from the mainland by narrow channels, which afford inland steamboat communication between Charleston and Savannah. These islands are low and flat, and produce the black-seed or sea-island cotton, the best known to commerce. Rice is also here produced in large quantities, and tropical fruits begin to flourish.—The topography of the state resembles that of the other states along the S. E. coast, but the mountainous district is not relatively so large as that of North Carolina. The coast for about 100 m. inward is flat and sandy, with a light soil, covered by pitch-pine forests, traversed by sluggish streams, and interspersed with numerous swamps. This portion of the state is of alluvial formation. Beyond this plain is a belt of low sand-hills called the middle country, which is moderately productive. West of the middle country is a belt called the ridge, where the land rises abruptly, and thence continues to ascend, exhibiting beautiful alternations of hill and dale, till it terminates at the extreme N. W. part of the state in the Blue Ridge, the highest peak of which, in this state, is Table mountain, 4,000 feet above the Atlantic. King's mountain, in York district, on the line between North and South Carolina, is an isolated mountain of considerable prominence. South Carolina has a great variety of soil, very little waste land, and produces cotton, rice, tobacco, maize, oats, rye, barley, sweet and Irish potatoes, peas, beans, &c. "The soil of the state," says Gov. Seabrook, "though of every kind, may be said to comprehend 6 varieties, each the best suited to a certain crop, yet all of them capable of advantageously producing  $\frac{4}{5}$  of the vegetable products grown in its limits." The 6 varieties here referred to are: 1, tide swamp, appropriated to the culture of rice; 2, inland swamp, to rice, cotton, corn, peas, &c.; 3, salt marsh, to long cotton; 4, oak and pine, to long cotton, corn, potatoes, &c.; 5, oak and hickory, to short cotton, corn, &c.; 6, pine barren, to fruits, vegetables, &c. The pine lands, embracing about 6,000,000 acres, are perhaps the most neglected section of the state. "The swamps," says Gov. Seabrook, "covering 2,000 sq. m. (1,280,000 acres), of inexhaustible fertility, are capable of thorough and economical drainage, and conversion into active and available capital." The state is nearly equally divided between the primary and alluvial formations; the former, of which oak is the natural growth, is broken

and hilly. The soil of much of the state is clay, which in the immediate vicinity of the ocean is almost universal substratum.—The gold-bearing the Atlantic slope extend through the portion of S. C., where the precious metal found in sufficient abundance to require the labor of the miner. In several places nuggets of pure gold have been found in gold-bearing veins have been discovered; those of the Dorn mine have been the most productive of any this side of the mountains, but the largest quantities have been obtained from surface workings. Ore of a good quality is also found in the same section of the state, but they have not as yet been very extensively worked. The granitic formations (upper country) of great abundance of building material. "The beautiful granites of the state," says Tuomey, "the porphyritic granite of the S. C. and Buffalo creek, and the red granite of Columbia, are conspicuous. Of the those found in Abbeville, Fairfield, and York are the most beautiful. The former resembles the Quincy granite, and the latter is remarkable for its white feldspar, which so strikingly with the black crystalline blende." White and variegated marbles found in Spartanburg and Laurens are of a quality sufficiently slaty to be used as flagging-stones, has been discovered in the lower part of York. Porcelain earth abounds through the regions, wherever the felspathic rocks are found in a state of disintegration. A fine quality exists in several localities, and yellow ochres abound in Chester district. Coal has not been found in the state, and the rock formations do not warrant the hope that it exists there.—In regard to climate, S. C. is favorably situated between the heat of the tropics and the frigid temperatures of the N.; and while the state grows quite all the vegetable products of the temperate zone, it also produces to some extent tropical fruits, though early frosts sometimes render the latter a precarious crop. The climate varies, of course, according to the elevation. The mean temperature of the state is stated from 8 years' observations to be 59°. There are 16,217,600 acres of farmland in the state, of which the census of 1850 shows 4,072,551 as improved. Farms and plantations, 29,967, averaging 541 acres each; plantations over 10,000 acres each, 16; farms and plantations, \$82,431,000; implements and machinery, \$4,136,300; age value of farms, \$2,751; of implements and machinery, \$138; cotton plantations producing 5 bales and over, 11,522; rice plantations producing 20,000 lbs. and over, 446. The farms of the state were 97,171 horses and mules, 193,244 milch cows, 568,935 other cattle, 1,065,503 swine. Value of

115; of slaughtered animals, \$3,502,687. Total product was 1,066,277 bush.; rye, 2,822,155; maize, 16,271,454; potatoes, 136,494; sweet, 4,387,469; barley; buckwheat, 283; hay, 20,925 tons; corn, 376 bush.; butter, 2,981,850 lbs.; lard, 1,970 lbs.; peas and beans, 1,026,900; produce of market gardens, \$47,286; products, \$35,108; beeswax and honey, 1,000 lbs.; value of poultry (1840), \$396,864; value of manufactures, \$909,525; wood, 1,740,340, 171,451; cane sugar, 77,000 lbs.; cotton, 15,904 galls.; ginned cotton, 120,000 lbs.; rough rice, 159,930,618; tobacco, 487,233; silk cocoons, 123; wool, 487,233; silk cocoons, 123; value of family goods (1840), \$1,000. The average product of the state per acre is: wheat, 8 bush.; maize, 11; oats, 12; corn, 30 lbs.; seed cotton, 320 lbs.; peas and beans, 3 bush.; Irish potatoes, 70. Manufacturing establishments in the state, 1,431; capital, \$6,056,865; raw material used, \$2,809,000; hands employed, 7,009; annual wages paid, \$32; annual product, \$7,063,513; profit, 10 per cent. Of these establishments, 18 were cotton factories, capital \$857,200, cotton used 1,000 lbs.; 6 were manufactories of iron castings, capital \$185,700; value of material used \$29,000; annual product \$87,683; 18 distilleries and breweries, capital \$3,475, corn used 18,100 bush., and high wines produced 43,900 galls. Exports of the state for the year ending 1857, were \$16,140,403, of which \$12,000,000 was the produce of foreign countries; exports from American vessels \$10,590,773, in foreign vessels \$5,549,630. Imports for same year, \$36, of which \$1,720,616 were in American vessels, \$299,170 in foreign vessels. Tonnage cleared, 153,002; in American vessels 105,000, in foreign 47,940. Number of vessels cleared, 262 were American. Tonnage cleared, 127,585, of which 83,205 tons were in American vessels. Number of vessels entered, 198 were American. During the year, 6 vessels were built in the state, 2 of which were schooners and 4 sloops; total tonnage, 1,000. Among the curiosities which invite the attention of the tourist, the most prominent is Mount Pisgah, 4,000 feet above the sea, and rises up perpendicularly on one of its peaks 100 feet above the surrounding country. A monument has been erected at its base, and it has become somewhat famous as a place of fashionable resort. "Cæsar's Head," a rock projection from its resemblance to the human cranium, is also a place of summer resort in the vicinity of Table Rock. Glenn's Spring, the waters of which are impregnated with iron and sulphur, is a watering place of note in Spartanburg district. The falls of the Saluda among the mountains have, according to Professor Tuomey, a descent of from 100 to 200 feet, and the region presents much of the most picturesque scenery.—Among the institutions of the state is a lunatic asylum

at Columbia, which is richly endowed, and is under the control of the state. On Nov. 5, 1855, there were 187 patients in this institution, of whom 100 were males and 87 females; 89 were paupers, and 98 pay patients. Receipts during the year, \$39,230 99; expenditure, \$38,087 67; discharged cured during the year, 22; removed, 11; died, 18. An asylum for the deaf and dumb at Cedar Springs, in Spartanburg district, is under the patronage of the state. The orphan asylum at Charleston is richly endowed, and has accommodations for 250 children. The state provides annually for the education, at the South Carolina college, of one youth from this asylum, to be selected as a reward of merit by the commissioners.—The census of 1850 reports 16 public libraries with 73,758 vols., 8 school libraries with 2,750 vols., and 7 college libraries with 30,964 vols.; also 46 newspapers, of which 10 are miscellaneous, 5 neutral, 24 political, 5 religious, and 2 scientific. Of these papers 7 are published daily, 5 tri-weekly, 27 weekly, and 5 semi-monthly. The aggregate circulation of these papers was, 55,715; annual number of copies issued, 7,145,930. There are 8 colleges in the state, with 43 teachers and 720 students; annual income \$104,790, of which \$41,700 is from the public funds, \$9,650 from endowments, and \$53,440 from other sources. The S. C. college at Columbia is a state institution, with 8 professors, and a library of 25,000 volumes. Academies and private schools, 202; teachers, 333; pupils, 7,467; annual income, \$205,489, of which \$226 is from the public funds, \$8,700 from endowments, and \$196,563 from other sources. Public schools (1850), 724; teachers, 739; pupils, 17,838; annual income, \$200,600, of which \$35,972 was from the public funds, \$3,000 from endowments, \$1,200 from taxation, and \$160,427 from other sources. Total number attending school in 1850, as returned by families, 40,878, of whom 21,792 were males, and 18,581 females; number of children between 5 and 15 years of age, 77,551; adults who could not read and write, 16,564, of whom 880 were free colored, and 104 of foreign birth. The school system of the state has been improved somewhat since 1850. The state now (1858) appropriates \$74,400 annually to free schools, which is distributed at the rate of \$600 to each representative in the popular branch of the legislature. Academies have been established, called arsenal and citadel academies, in which the youth are practically educated in military tactics, and in engineering and surveying.—The census returns 1,182 churches in the state, of which 413 are Baptist, 484 Methodist, 136 Presbyterian, 72 Episcopal, 41 Lutheran, 5 Free, 3 Jewish, 14 Roman Catholic, 3 Universalist, 1 each Congregational, Friends, and Unitarian, and 8 of minor sects. Total value of church property in the state, \$2,172,246, viz.: Baptist, \$393,863; Episcopal, \$616,950; Methodist, \$341,168; Presbyterian, \$483,175; Congregational, \$70,000; Free, \$1,700; Friends, \$500; Jewish, \$83,700; Lutheran, \$109,500; Roman Catholic, \$78,-

815; Unitarian, \$30,000; Universalist, \$6,000; minor sects, \$57,875. The churches afford accommodation for 460,450 persons, viz.: Baptist, 165,850; Congregational, 2,000; Episcopal, 28,940; Free, 1,550; Friends, 500; Lutheran, 14,750; Methodist, 165,740; Presbyterian, 67,765; Roman Catholic, 6,030; Unitarian, 700; Universalist, 950; minor sects, 3,320.—The first state constitution was formed in 1775, and the present one was adopted in 1790. It vests the executive authority in a governor, who is elected for 2 years by a joint vote of the legislature, at each first meeting of the house of representatives. The governor is ineligible to the same office for the next 4 years after the expiration of his term. He receives \$3,500 per annum, and house rent. A lieutenant-governor is elected in the same manner, and for the same term, who acts as governor in the case of the death or removal from office of the governor. Presidential electors are also chosen by joint vote of the legislature. The legislative authority is vested in a general assembly, consisting of a senate of 45 members, who are elected by districts for 4 years, one half biennially, and a house of representatives of 124 members, apportioned among the several districts, on a basis of white inhabitants and taxation, elected for 2 years; this body and one-half the senators being elected every second year, on the 2d Monday in October, and the day following. Members of the legislature receive \$3 per diem, and 10 cents per mile travelling fees. The general assembly meets annually on the 4th Monday in November, at Columbia. South Carolina has 6 representatives in the popular branch of congress.—The judicial power is vested in such superior and inferior courts of law and equity as the legislature shall from time to time establish. The judiciary of the state is at present (1858) as follows: 1. The law court of appeals, and equity court of appeals; the former consisting of all the law judges, for hearing appeals from the courts of law, and the latter of all the chancellors, for hearing appeals from the courts of equity; two sessions are held at Columbia and one at Charleston annually; 2. courts of equity, presided over by 4 chancellors, who take cognizance of all matters belonging to a court of equity, as contradistinguished from a court of law; a term is held by one chancellor annually in each district except Charleston, where 2 terms are held; 3. courts for the correction of errors, consisting of all the judges in law and equity, to try constitutional questions, or questions where the law and equity courts are divided; 4. courts of common pleas and general sessions, having original jurisdiction in all civil cases where legal rights are involved (except matters of contract where the amount is \$20 or under), and in all criminal cases affecting free white men, appellate jurisdiction in all appeals from magistrates' courts, and in appeals from the court of ordinary in all cases except in matters of account; these courts are held in each district twice annually; 5. city court

of Cl  
p  
court, in each  
istration, pro  
administrators accounts, etc.;  
courts, having exclusive jurisdiction in  
ters of contract for \$20 and under; 8. courts  
of magistrates for the trial of slaves and free  
persons of color for criminal offences.—The  
actual debt of the state on Oct. 1, 1856, was \$1.  
693,276 50, consisting of 3, 5, and 6 per cent. state  
stocks and bonds, on which the annual interest is  
\$149,527 88. The state has subscribed \$300,000  
to the stock of the Blue Ridge railroad co., yet to be called for, which will increase its  
debt to \$3,293,276 60, and the annual interest to \$179,527 88. The state also owes a  
contingent debt of \$4,051,422, of which \$1,051,422 is U.S. surplus revenue deposit, \$2,000,000  
guarantee of the bonds of the S. C. railroad co., and \$1,000,000 guarantee of the bonds of the  
Blue Ridge railroad co. The new capitol will create an additional debt, which is to be covered  
by a 6 per cent. stock. The assets of the state amount to \$6,243,114 54, viz.: the surplus assets  
of the state bank \$4,500,814 54, and stock in various railroad companies \$1,742,300. The  
receipts into the state treasury for the year ending Sept. 30, 1856, were \$593,962; balance, Oct. 1, 1856, \$136,809 64, making the total income \$730,771 64. Total expenditure for the year, \$591,145 98; balance, Oct. 1, 1856, \$139,625 66. The chief sources of income were: general taxes, \$501,771 87; dividends on railroad shares, \$14,582; new state capitol, \$73,875 86. The principal items of expenditure were: military academies, \$30,010; new state capitol, \$71,514; free schools, \$77,539; jurors and constables, \$30,906; public buildings, \$53,165; salaries of public officers, \$80,090; Charleston harbor, \$42,196; legislative certificates, \$15,981. The subjects of taxation in 1856 were: 287,319 slaves, \$290,488 50; 2,934 free negroes, \$5,868; sales of merchandise, \$58,842; faculties, professions, &c., \$10,794; banks and bank stock, \$25,679; premiums of insurance co., \$1,836; town lots, \$73,665; 17,443,791 acres of land valued at \$10,284,001, \$61,703; total, \$52,744.—On Jan. 1, 1857, there were 20 banks and branches in the state; capital, \$14,837,643; loans and discounts, \$28,227,370; specie, \$1,197,774; circulation, \$10,654,653; deposits, \$3,502,733.—On Jan. 1, 1857, S. C. had 734 m. of railroad built, viz.: S. C. railway, from Charleston to Augusta, Ga. (with branches to Camden and Columbia), 232 m. long, capital paid in \$4,200,000; debt, funded and floating, \$2,750,000, cost of construction and equipment \$7,150,000; Charlotte and S. C., from Charlotte, N. C., to Junction near Columbia, S. C., 160 m., capital \$1,201,000, debt \$380,000, cost of construction and equipment \$1,720,000; Greenville and Columbia, from Columbia to Greenville 166 m., capital stock \$1,205,000, debt \$970,000, cost of construction and equipment \$2,000,000; N. Eastern, from Charleston to

## SOUTH CAROLINA

ence, 102 m., where it intersects the Wil-  
 and Manchester railroad; Cheraw  
 ngton, from Florence to Cheraw, 40  
 are several other shorter roads in  
 amounting in all to 75 m. There are  
 several other roads in course of construc-  
 and in contemplation. Of the former are  
 Blue Ridge road extending from Aiken,  
 J. (where it intersects the S. C. road) in a  
 W. direction to Knoxville, Tenn., and the  
 barl n and Savannah, designed to unite  
 ues by a route a few miles back from  
 west; of the latter a road along the coast  
 and Charleston to Wilmington, N. C., from  
 N. E. to Raleigh, N. C., from Spartan-  
 N. W. to Ashville, N. C., from Green-  
 N. to Ashville, and from Greenville N.  
 to Waynesville, N. C.—The first attempt at  
 colonization in S. C. was made by  
 of French Huguenots under John Ri-  
 who was sent out with 2 ships in  
 on a voyage of exploration to Florida.  
 having discovered in May of that year the  
 river St. John's, which he named the river of  
 he coasted northward, and finally entered  
 sious inlet which he named Port Royal,  
 on an island in this harbor built a fort,  
 Carolina, after Charles IX. of France—a  
 afterward extended to the circumjacent  
 y, and still retained by 2 of the American  
 He left here 26 colonists, and returned  
 supplies; but soon becoming dissatisfied,  
 tinied, killed their commandant, and  
 up a rude craft, sailed for France. After  
 ring very great hardships, they were picked  
 by an English vessel, and taken to Europe.  
 next, and first permanent settlement in S. C.,  
 le by English colonists at Port Royal  
 1670, who removed the following year to  
 Charleston, on the W. side of Ashley river,  
 again in 1680 to the present site of Charles-  
 Under the name of Carolina, both the  
 states were held as a proprietary govern-  
 ominally under the celebrated model con-  
 nition, prepared by John Locke, till July, 1729,  
 hen the king bought out the proprietors, and  
 med the Carolinas into 2 separate royal col-  
 ies. In 1685 a large number of French  
 uenots settled in S. C., and subsequently there  
 re considerable settlements of Swiss, Irish,  
 l German emigrants. The colony, at various  
 es, suffered severely from Indian depredations,  
 l was with Georgia engaged under Oglethorpe  
 a contest with the Spanish settlements in  
 rida. South Carolina was the scene of severe  
 rfare during the revolutionary struggle, many  
 ly contested battles being fought with vary-  
 success, viz.: at Fort Moultrie, Charleston,  
 nden, King's Mountain, Eutaw Springs, Cow-  
 is, &c. The British held the country for the  
 ater part of the years 1780 and 1781. The  
 y severe battle of Eutaw Springs, Sept. 1781,  
 ween Gen. Greene and Col. Stuart, in which  
 h es claimed the victory, was the last en-  
 ment of any importance during the revolu-  
 ary contest. Since the revolution, South

## CAROLINE AMALIA ELIZABETH 467

Carolina has grown into a wealthy and prosper-  
 ous state, has taken an active part in national  
 affairs, and furnished many eminent statesmen  
 and legislators.

CAROLINA MARIA, queen of Naples,  
 daughter of the Austrian emperor Francis I.  
 and Maria Theresa, born Aug. 18, 1752, died  
 at Schönbrunn, Sept. 8, 1814, married, Aug. 12,  
 1768, Ferdinand IV., king of the Two Sicilies,  
 over whom she exercised an unbounded in-  
 fluence, which led to fatal results, especially  
 when, in 1784, she prevailed upon the king to  
 appoint her favorite Joseph Acton prime min-  
 ister. A great share of the odium of Acton's  
 measures fell upon the queen. In 1798, Ferdi-  
 nand IV., at the instigation of Carolina, de-  
 clared war against the French republic; but  
 after the defeat of the Austrian army under  
 Mack, the French marched upon Naples, and  
 the royal family was compelled to fly to Sicily,  
 and to put themselves under British protection.  
 Cardinal Ruffo's agitation in Calabria against  
 the French and the Neapolitan republicans, per-  
 mitted the king to return to Naples in 1799;  
 but here new intrigues were opened by Carolina,  
 who, on this occasion, had the pernicious as-  
 sistance of Lady Hamilton. In 1805, Carolina  
 joined the coalition against Napoleon, but not-  
 withstanding the assistance given to Naples  
 by Russia and England, she and her husband  
 were again expelled from their dominions. She  
 found in the British general, Lord Bentinck, who  
 was bent on neutralizing her injurious influence,  
 an opponent with whom she was unable to con-  
 tend. She retired and went to Vienna in 1811,  
 and died before the restoration of Ferdinand  
 IV. to the throne. This queen was notoriously  
 ambitious and anxious to grasp political power,  
 which, however, she was unable to manage, al-  
 though she possessed a certain degree of ability.

CAROLINE. I. An eastern county of Mary-  
 land, bordering on Delaware, intersected by the  
 Choptank and Marshy Hope rivers; area, 800  
 sq. m.; pop. in 1850, 9,692, of whom 808 were  
 slaves. The surface is flat and the soil sandy.  
 Productions in 1850, 835,520 bushels of corn,  
 42,879 of wheat, 17,422 of oats, and 41,864  
 lbs. of butter. Number of pupils in the public  
 schools, 518. Capital, Denton. II. An eastern  
 county of Virginia, with an area of 480 sq. m.;  
 pop. 18,456, of whom 10,661 were slaves;  
 bounded on the N. by the Rappahannock and  
 intersected by the Mattaponi. The surface is  
 diversified, and the soil of the river bottoms is  
 good. Productions in 1850, 629,994 bushels of  
 corn, 178,353 of wheat, and 668,155 lbs. of to-  
 bacco. Number of pupils in the public schools,  
 616; value of real estate in 1856, \$3,862, 988.  
 Capital, Bowling Green.

CAROLINE AMALIA ELIZABETH, queen  
 of England, daughter of Duke Charles Wil-  
 liam Ferdinand of Brunswick and the princess  
 Augusta of England, born May 17, 1768, died  
 Aug. 7, 1821. In 1795 she married her cousin  
 the prince of Wales, but in the ensuing year,  
 after she had borne him a daughter (Charlotte),

the prince, who had married her reluctantly, separated from her, and Caroline retired to a residence at Blackheath. Looked upon as the victim of a profligate husband, her position enlisted much sympathy on the part of the people at large, especially as she was known to be of a kind and generous disposition, but at the same time subjected her to serious charges on the part of her enemies. In 1808, George III. instituted an inquiry into her conduct, which absolved her from any positive dereliction of duty, without, however, acquitting her of the imputation of improprieties into which her warm and impulsive temperament was but too apt to lead her. In 1814 she received permission to visit her native town and to travel in Italy and Greece, and subsequently resided chiefly in a villa on the lake of Como. Her relation with Bergami, an Italian connected with her household and who accompanied her in her travels, gave rise to a new series of rumors disparaging to her honor. On Jan. 29, 1820, her husband ascended the throne as George IV., when a pension of £50,000 was offered her on condition that she should never return to England. The queen not only rejected this offer with contempt, but, to the consternation of the court, arrived in England on June 5 of the same year, the masses of the people, who never withdrew their sympathies from Caroline, receiving her with enthusiastic acclamations. A charge of adultery, however, was brought against her by the king before the house of lords, which, as partisan feelings were blended with the intrinsic interest of the case, created the greatest excitement in England. The house of lords, by a majority of 108 against 99, passed a bill of pains and penalties intended to apply to her case; but public opinion was so strongly in her favor, that the prosecution was abandoned by the government, Caroline remaining in the uncontested possession of her rank and title as queen, and living in regal style at Brandenburg house. The trial made the fortune of the lawyers employed on her behalf, the present Lord Brougham, the late Lord Denman, and the recently deceased Sir Thomas Wylde, and others, and furnished for a considerable time rich food to the lovers of scandal. Caroline, however, was deeply affected at the result, and the moral shock received on this occasion accelerated her death, which took place in the ensuing year. The humiliation of seeing the doors of Westminster abbey shut against her, when, in July, 1821, she presented herself to attend the coronation of George IV., was the last blow dealt out to her by her enemies before she died. Her funeral gave rise to disturbances at London and Brunswick, the people attributing her death to her opponents. Popular sympathy followed her to her grave; not that the people believed in the total purity and innocence of her life, but there was a great unwillingness to place reliance upon any charges emanating from George IV., especially when a queen was concerned whom he had treated with so much revolting brutality.

## CAROLINE

PINES, one of the ~~the~~ between the P Marshall Islands, ~~and a group~~ from lat.  $3^{\circ} 5'$  to  $12^{\circ}$  N., are ~~and are~~ of 2,000 m. from W. to E., and are numerous groups. The western Palaoas or Pelew, consist of a number of small islands, all of ~~coral~~. They are generally flat, and afford ~~no~~ anchorage. North-east of these is the group of Yap, the principal island of which is mountainous and rich in precious metals. The islands of Egoi, resembling the Palaoas in surface and formation, lie east of Yap; they are fertile islands and are partly inhabited. The easternmost island, called Ulalan, is 24 m. in circumference, and has abundant supplies of water, fruit and fish. The climate of the Carolines is mild and agreeable. The inhabitants, most of whom are of the Malay race, are generally fishermen, and make excellent sailors. The Carolines were discovered in 1543 by Lopez de Villalobos, and were named in honor of Charles V. Nominally they belong to Spain and form part of the government of the Philippines, but there are no Spanish settlements on any of them.

CAROLINE MATILDA, queen of Denmark, daughter of Frederic Lewis, prince of Wales, sister of George III., born July 21, 1751, died at Celle, May 10, 1775, married in 1766 Christian VII., king of Denmark, and in 1768 became mother of King Frederic VI. By her fine personal qualities she endeared herself to all around her, excepting the queen dowager, Sophia Magdalen, and Juliana Maria, the king's stepmother, who were jealous of her influence, and treated her with marked hostility. Their dislike to the young queen assumed a still more formidable character, when Struensee, the physician and special favorite of the queen, rose to supreme power in Denmark, and in concert with his royal mistress played into the hands of the liberal party, while the queen dowager and Juliana Maria were fanatical partisans of the old Danish aristocracy. At the same time grave imputations were cast by them upon the queen's honor, as in 1771 she was delivered of a daughter, which was attributed to an illicit connection with Struensee. The ruin of the queen and her favorite was resolved upon by the queen dowager and her party, and on the night of Jan. 16, 1772, during a ball at the court, Struensee, and the queen were arrested. The unfortunate minister and his friend Brandt were sentenced to death, and Caroline with her little daughter (the future duchess of Augustenburg), barely escaping the same fate, were consigned to Kronborg castle. But for Lord Keith, the British minister at Copenhagen, more stringent measures would have been taken against her; as it was, a separation from her husband King Christian (who by his semi-idiotic condition had long since ceased to possess any personal influence) was agreed upon,

elle in Hanover assigned to her as a place of residence, where, worn out by sorrow, she died after a few years. A monument has been erected to her in Celle. Lenzen has published her last hours, containing the celebrated letter written by the queen to her son George III., in which she solemnly asserts her innocence.

CARON, or CARRON, FRANÇOIS, a Dutch navigator, who perished by shipwreck off the coast of Japan in 1674. He was of a French Protestant family which had taken refuge in the Low Countries. He engaged when very young as a stant cook on board a vessel departing for Japan. During the voyage he applied his moments of leisure to the study of arithmetic, and, after his arrival in Japan, learned the Japanese language. This acquisition rendered him especially useful to the Dutch East India company, and he became director of commerce with Japan, and a member of the Council of India. Colbert was at this time striving to give to France some importance in the commerce of the East Indies, and sought among the European nations men capable of seconding his views. In 1667, Caron accepted letters patent appointing him director-general of the French commerce in India; but, at the same time, other Dutch and French merchants were joined with him with the same title. Caron arrived in 1667 at Madagascar; but, finding the French offices at that place in hopeless confusion, it was decided that he should remain there. He departed for Surat, which seemed a more favorable centre, and began his operations there with good success. Several of his subsequent plans and operations proved unfortunate, and his imperious and avaricious character had also excited many enemies against him at court. The minister was constrained to leave him; and, that Caron might not suspect any hostile motive, it was pretended to him that his advice was needed with reference to new enterprises. He immediately embarked for the Indies, having on board immense riches, which he had already passed the straits of Gibraltar, when he was informed, by a vessel which he met, of the disposition entertained concerning him at court. He at once turned his ship about and directed his course to Lisbon. He had already anchored in this port, when a heavy sea struck his vessel against a rock, and it went to the bottom with its passengers and cargo. One of the sons of Caron alone was saved.

CARONY, or CARONI, a river of Venezuela, rises in the Sierra Pacaraima, and after a rapid course of about 400 m., broken by numerous rapids, joins the Orinoco.

CARROR, a town of British India, in the presidency of Madras, district Coimbatore, on the Caverry river, lat. 10° 58' N., long. 78° 9' E., 10 m. W. from Trichinopoly. It contains about 100 houses, has near it a fort and a large temple, and has been in the possession of the British since 1760.

CARORA, or CARORO, a town of Venezuela, in the Tocuyo, in the province of Barquesimeto;

pop. 8,000. It contains a handsome parish church, a hermitage, and a Franciscan convent. The district in which it stands is famous for its aromatic balsams, resins, gums, and a kind of wild cochineal.

CAROUGE, a town of Switzerland, on the Arve, in the canton of Geneva; pop. 5,000. It was ceded to Switzerland in 1816, until which time it had been the capital of the Sardinian province of Carouge, which was suppressed in 1837. The town is regularly built, pleasantly situated, surrounded by elegant villas, and connected with Geneva by a bridge. It has manufactures of watches, thread, leather, and clay pipes.

CAROVÉ, FRIEDRICH WILHELM, a German critical writer, born at Coblenz, June 20, 1789, died in Heidelberg, March 18, 1852. He commenced life as an advocate, held some judicial offices, was made doctor of philosophy by the university of Heidelberg, and officiated for a short time as professor at Breslau. He was one of the founders of the Heidelberg Burschenschaft, or students' secret political association, and participated in the famous Wartburg festival. He was afterward a member of the provisional German parliament of 1848. His most elaborate works are attacks on the Roman Catholic religion, such as "The Church, which alone works our Salvation," and an "Essay upon the Celibacy of the Catholic Clergy." His powers of criticism are shown in his "Religion and Philosophy in France," "Essay on St. Simonism," "The New French Philosophy," &c.

CARP, a malacopterygian fish, of the family *cyprinidae*, genus *cyprinus*, having the body covered with large scales, a single elongated dorsal fin, fleshy lips, small mouth, with a barbel at the upper part of each corner in the common species, and a smaller one above; teeth in the pharynx, but none in the jaws; branchial rays 3; the ventrals behind the pectorals, without any connection with the bones of the scapular arch; the 2d dorsal ray and the 1st anal serrated posteriorly; the tail forked; 12 rows of scales between the ventral and dorsal fins. The *C. carpio* (Linn.), is of a golden olive-brown color above, yellowish beneath, and the fins dark brown. It inhabits the fresh-water lakes and streams of central and southern Europe, whence it has been spread by man over the northern parts. It is noticed by Aristotle and Pliny, but was not held in much estimation in ancient times; it grows rapidly, lives to a considerable age, and is exceedingly prolific; it seems to have been introduced into England about 800 years ago. They prefer quiet waters, with soft or muddy bottoms, spawning in May or June, according to locality; the food consists of larvæ of aquatic insects, worms, and soft plants, though they eat almost any vegetable food in artificial ponds. They are very tenacious of life, and will pass long periods, especially in winter, without food; they afford but little sport to the angler, being very uncertain, and are difficult to take in nets. The size

varies from  $\frac{1}{2}$  to  $2\frac{1}{2}$  feet, and their weight from 1 to 18 lbs.; they are in season from October to April, and are generally considered excellent for the table. Dr. Storer describes the common carp of Europe as having been introduced into New York from France. The gold-fish, or golden carp, is the *C. auratus* (Linn.). The crucian carp (*C. gibelio*, Bloch.), is of smaller size, and is considered by some the same as the *C. carassius* (Bloch.). In this country the name of carp is erroneously applied to some species of *catostomus* and *luxilus*, belonging to the same family of fishes.

CARPÆA, among the ancient Greeks, a kind of mimetic dance peculiar to the Ænians and Magnes. It was performed by 2 armed men, one representing a ploughman, and the other a robber, in the following manner: The laborer, laying aside his arms, begins to plough with a yoke of oxen, frequently looking around as if in alarm. When the robber at length appears, the ploughman snatches up his arms, and a fight begins for the oxen. The movements are rhythmical, and accompanied by the flute, and at last the victor takes away the oxen and plough for his reward.

CARPANI, GIUSEPPE, an Italian dramatist and writer on music, born at Villalbese, near Milan, Jan. 28, 1752, died in Vienna, Jan. 22, 1825. Having prepared himself for the profession of the law, he afterward devoted himself to literary pursuits, and produced a great number of plays and operas partly translations and partly original. In 1792 he was editor of the *Gazzetta di Milano*, and wrote violent articles against the French revolution. He was obliged to leave the city after the invasion of the French, and went to Vienna, where he was appointed censor and director of the theatre. In 1809 he accompanied the archduke John in the expedition against Napoleon. Under the title of *Haydine*, he published a series of curious and interesting letters on the life and works of his friend Haydn the composer. These letters, published in a French translation as an original work by L. A. C. Bombet, or, as other biographers state, by Beyle (known under the *nom de plume* of Stendhal), gave rise to a great literary controversy, in which Carpani vindicated his authorship most successfully.

CARPATHIAN MOUNTAINS, a mountain system in central Europe, lying N. and E. of Hungary, which it separates from Poland, Russia, and Turkey. The entire range forms a semicircle about 800 m. long, commencing at New Orsova, on the Turkish frontier of Austria, where it is separated from the Balkan range only by the Danube, and terminating in the lofty rock on which the castle of Presburg is situated. Their breadth varies from 100 to 250 m. The highest eminences are in the E. or Transylvanian section, where the peaks of Poyana-Ruska, Garluvi, and Buthest, rise to the height of about 9,000 feet. There are parts of this section, however, which have never been explored, and hardly visited by man, and of

which no highest

pathians as in Carpathes of the Carpathians, Gerlsdorf, and Vial up their naked granite vation of over 8,000 feet of the whole Carpathian granite. Sandstone and li at a lower level, and b petrosilex, lava, obsidian, substances, the result of action, are scattered in the among the lower ranges. No traces recent volcanic eruptions, tho questionable evidence of the of fire and water at some thians stand preëminent of Europe in respect to minerals every metal is produced abund sides. There are mines of Kremnitz and at Schemnitz a gold mine at Nagy Agin Trai has been esteemed the Iron, copper, lead, and in large quantities, and deposits throughout both The Carpathians present 4 zones of rising successively. There is region, where the oak, beech, thrive, which reaches to a height of 4,000 feet above the sea. Then the or Scotch fir, appears, and oc 1,000 feet. This is succeeded by and useless moss-pine, which diminish as the elevation increases, and at 6,000 feet appears only as a scattered patches. The open region produce a few blue-bell flowers. From the termin pine to the summit, the barren and dreary look, being of naked rock, or covered lichens; yet even at these a blue-bell or gentian may None of the Carpathians are perpetual snow. Numerous these mountains facilitate between the countries ly most remarkable and those of Terego, leading to Temesvar; of Vulcan, in which the Schyl flows; in a gorge formed by the Mt. Szurul. This pass Bem's most brilliant revolutionary war of Hungary were strongly fortified of the Turks into them have, nevertheless, forced.

CARPATIUS, the ancient name of the island of Scarpanto, lying between Rhodes and Crete, about 80 m. from the former. Hence the surrounding sea was called *Mare Carpathium*.

CARPENTER, LANT, LL. D. an English Uni-

minister, born at Kidderminster, Sept. 2, and April 5, 1840. He was of a Nonconformist family, and on the death of his father was educated by Mr. Pearsall, a relative of his mother. Designed for the ministry, he went in 1797 to the Northampton academy, that school being temporarily discontinued. Carpenter was placed at Glasgow where, however, he did not continue long on account of time necessary to take his degree.

When he entered college in 1801, he spent some time as librarian of the Athenæum, and as a student. While at the academy he became acquainted with many of the students, obnoxious to the trustees, on account of doctrinal views far from the reputed standards of orthodoxy. This defection of the students was the cause of the suspension of the school. In the school, Carpenter's views were so clearly at variance with those of the Unitarian denomination, generally, that he received several invitations to the pastoral charge of Unitarian churches, and a call to a professorship in theology at York. In 1805 he finally accepted a call to succeed Dr. Thomas Kenrick at Exeter, where he continued for 12 years. In 1817 the university of Glasgow gave him the degree of D.D., although he had applied only for the degree of M. A. From Exeter he removed to the pastoral charge of the Unitarian congregation at Bristol (1817), where he continued until his death, which occurred by falling from a vessel at Naples and Leghorn, while on a tour of health. The body afterward floated on the coast of Porto d'Anzo, the ancient Antium, and was buried on the seashore.

Dr. Carpenter was of an eminently practical turn. The instruction of children was an object of his great interest. Amid all his pastoral and domestic labors, which were arduous above most men, he always found time and opportunity to devote to juvenile instruction, and to combat the prejudices of his congregations, by opening Sunday schools among the children of the poor at Exeter and Bristol. An instance of his love of education is recorded in his biography, which is of notice, both for the evidence it affords of his character, and as an interesting chapter in Sunday school history. His guardian, Mr. Pearsall, had established at Kidderminster, in conjunction with Robert Raikes at Gloucester, a Sunday school for the instruction of the poor of the working classes. Carpenter was but 11 years of age; but his practical sense did not overlook the opportunity for a better service he could render to those

They went to their work at 5 o'clock in the morning. He therefore assembled them at 6 o'clock every day in the week, and gave them lessons in arithmetic an hour before the time of daily toil. These lessons were given in a summer-house under a mulberry tree, and in a summer-house, without any fire. In his pastoral charges at Exeter and Bristol, he was in coöperation with others in the management of libraries, schools, savings

banks, and institutions for general improvement and welfare. His published works are mainly theological and doctrinal, in support of the Unitarian sentiments he had early espoused. Among his more important works are "An Introduction to the Geography of the New Testament," "Unitarianism the Doctrine of the Gospel," "Examination of the Charges against Unitarianism," "Harmony of the Gospels," and a volume of sermons. Mild in controversy, faithful in humane labors, and practically devoted to the improvement of society, Dr. Carpenter was respected even by those who were his most decided antagonists in theology.

CARPENTER, WILLIAM BENJAMIN, an English physiologist, son of the preceding, born in the early part of this century, was originally intended for an engineer, but graduated as doctor of medicine at Edinburgh in 1839. One of his earliest papers, published in the "Edinburgh Medical and Surgical Journal," was on the "Voluntary and Instinctive Actions of Living Beings," and in these and other early papers he laid the foundations of those views which he afterward developed more fully in his "Principles of General and Comparative Physiology, intended as an Introduction to the Study of Human Physiology, and as a Guide to the Philosophical Pursuit of Natural History" (8vo. London, 1839). This work was deemed a most remarkable production for so young a man. A 3d edition appeared in 1851. After receiving his diploma in Edinburgh, he settled in Bristol, with a view of practising his profession, but accepted an appointment as lecturer on medical jurisprudence in the medical school of that city. In 1843, and subsequent years, he wrote the "Popular Cyclopædia of Science," embracing the subjects of mechanics, vegetable physiology and botany, animal physiology and zoology. These were professedly compilations, but they are well written, and contain original views on many points of interest. In 1846 he published his work on the "Principles of Human Physiology," which reached a 5th edition in 1855. Dr. Carpenter may not have repeated all the experiments of other observers, but he is able to appreciate correctly the facts observed by others; and in those departments of physiology and biology which lie beyond the region of experiment, and demand the more subtle analysis of a logical mind, the science of physiology, observes his English biographer, has probably no more accomplished exponent. In 1854 a 4th edition of his "Principles of Comparative Physiology" was published, to be followed by the "Principles of General Physiology," in 1 volume. These 2 works, with that "On Human Physiology," form 3 independent volumes, comprising the whole range of biological science as at present known. The articles on the "Varieties of Mankind," the "Microscope," on "Smell," "Taste," "Touch," on "Sleep," "Life," "Nutrition," and "Secretion," published in the "Cyclopædia of Anat-

omy and Physiology," are also from the pen of Dr. Carpenter. Having written much as a popular disseminator, as well as an original investigator of science, he has been accused of being a plagiarist and mere compiler. In answer to this charge, he claims, in the preface to the 8d edition of his "General and Comparative Physiology," the following facts and doctrines as his own: 1. The mutual connection of vital forces, and their relation to the physical. This doctrine is fully developed in a paper on the "Mutual Relations of the Vital and Physical Forces," in the "Philosophical Transactions" for 1850. 2. The general doctrine that the truly vital operations of the animal as well as the vegetable organism are performed by the agency of untransformed cells, which was first developed in an "Essay on the Origin and Functions of Cells," published in the "British and Foreign Medical Review" for 1843. 3. The organic structure of the shells of mollusca, echinodermata, and crustacea, of which a full account is contained in the "Reports of the British Association" for 1844 and 1847. 4. The application of Von Baer's law of development from the general to the special, to the interpretation of the succession of organic forms presented in geological time. 5. The relation between the 2 methods of reproduction, that by gemmation and that by sexual union, with the application of this doctrine to the phenomena of the so-called "alternations of generations;" first developed in the "British and Foreign Medico-Chirurgical Review" for 1848 and 1849. 6. The relation between the different methods of sexual reproduction in plants; first developed in the "British and Foreign Medico-Chirurgical Review" for 1849. 7. The application of the doctrine of reflex action to the nervous system of invertebrata, especially articulated animals; first developed in the author's prize thesis, published in 1839. 8. The functional relations of the sensory ganglia to the spinal cord on the one hand, and to the cerebral hemispheres on the other.—In 1856, Dr. Carpenter published his work "On the Microscope, its Revelations and its Uses" (a 2d edition appeared in 1857), in which he displayed the same industry, accuracy, and impartiality as in his other writings. A new and thoroughly revised edition of his work on "Zoology" appeared in 1857. He has also published several interesting papers on the fossil forms of the family of *foraminifera*, and is said to be preparing a work on the structure, functions, and general history of this group of animals, for publication by the Ray society. He is now professor of medical jurisprudence in university college, London; lecturer on general anatomy and physiology at the London hospital and school of medicine; examiner in physiology and comparative anatomy in the university of London. In 1844 he was admitted a fellow of the royal society. In 1849 he gained the prize of 100 guineas offered for the best essay on the subject of "Alcoholic Liquors." This essay

was published with great popularity among all classes, and among the advocates of temperance. Dr. Carpenter was a member of the "British and Foreign Medico-Chirurgical Review," and while thus occupied with his pen, he was also much engaged in lecturing. He is not an orator, nor even a fluent speaker, but he is always master of his subject, and by his clear and methodical explanation of the facts and principles of which he treats, his audience is always deeply interested. In private life he is a man of simple and ingenuous deportment, beloved and respected by all who know him. On Sunday mornings he performs gratuitously the functions of organist for a small Unitarian congregation at Hampstead, near London.—RUSSELL LANT, a brother of the preceding, officiated for some time as Unitarian minister at Birkenhead, and more recently at Hull, and is author of a volume of sermons and of the memoirs of his father.—PHILIP, another brother, is minister of the poor at Warrington, and author and publisher of many tracts for the poor and ignorant.—MARY, sister of the foregoing, a philanthropist, founder and promoter of ragged schools, and juvenile reform schools in Bristol, and one of the lecturers at the recent meeting of the association for the promotion of human science, of which Lord Brougham was author and president. She has also compiled a book, entitled "Morning and Evening Devotion," and several works of a practical character.—MARGARET, an English portrait painter, born at Salisbury in 1798, the daughter of the late Mr. Alexander Reynolds Geddes, who was an accomplished artist. Having enjoyed many opportunities of study, Miss Geddes sent at an early period pictures to the society of arts, which were favorably received, especially the study of a boy's head, for which the large gold medal was awarded. Miss Geddes repaired to London in 1814, and married in 1817 Mr. W. H. Carpenter, who is keeper of the prints and drawings of the British museum. Mrs. Carpenter's productions have figured meritoriously for many years at the exhibitions of the royal academy and the British institution.

CARPENTRY, the art of forming combinations of timber for resisting to best advantage the effects of weight and pressure. The subject demands, 1st, the consideration of the scientific principles involved; and, 2d, the practical details of carpenters' work. The former, which can be but briefly noticed, mainly depend upon the laws governing the strength of materials, and composition and resolution of forces. To calculate the strength of the combinations resort is had to the parallelogram of forces, by the aid of which the resultant pressure is readily determined in any system of framing, however complicated. An important rule to be observed is, that stiffness or rigidity of form in any framework is of greater consequence than the comparative strength, as any modification of the latter can always be

ed by varying the strength of the different parts. The triangle being the only form of which cannot be changed, it is evident that the rigidity of framework can be best secured by the adoption of a truss system—that is, by dividing the framework into a system of triangles, by means of ties and struts. The latter are the members employed to resist the effects of compression; the former, those of extension. This action must be closely observed in planning any system of framework, as a confusion of members might prove destructive to the work. When a single beam is to be strengthened by the application of a system of members, the combination is termed a truss, and the beam is said to be trussed. In all designs of framing, this principle is to be borne in mind, and the strength of the weakest point is assumed as the strength of the entire system.—We pass now to the consideration of carpentry as a mechanical art. The materials are received by the carpenter in the form of beams, scantlings, planks, and boards, out of which he constructs the bond timbers, wall plates, and the various elements of floors and roofs. His labors are limited mainly to the skeleton of the structure—to those portions which are indispensable to its stability and efficiency; while its adaptation to the purposes of convenience and ornament is intrusted to the care of the joiner, plasterer, plumber, &c. The tools employed by the carpenter are the rule, axe, saw, adze, mallet, chisels, hammers, augers, gouges, hook pins, marking line, square, bevel, gauge, compasses, level, and plumb line. Beside these, which are indispensable, he also occasionally makes use of planes, sledge-hammers, gimlets, pincers, raffles, wedges, and crow-bars. The operations he performs are principally scarfing, notching, cogging, tenoning, pinning, and bedding. Scarfing is a mode of connecting beams longitudinally, and is performed by cutting away half the substance of each beam for a certain length, bringing the cut portions together, and fastening them by screws, bolts, or wedges. Where strength only is required without regard to appearance, beams may be lengthened by “fishing,” instead of scarfing. In this, the beams are brought end to end, and lapped on opposite sides with short pieces of strong plank, which are secured by bolts which pass through both pieces and the beams between them. If bolts and straps are applied, this form of joint is as well adapted to resist transverse as longitudinal strains. In designing scarfs, the kind of strain to which a piece is to be subjected, whether longitudinal, transverse, or a combination of both, is to be particularly considered. In the ordinary framing no provision is made for resisting longitudinal strains, except so far as the bolts may answer this purpose, and also the adhesion or cohesion of the 2 beams. More elaborate methods of jointing are therefore devised, in

which the resistance of wood to splitting is employed to secure the pieces, which are drawn together by the aid of keys or double wedges. Bolts and straps may also be used to impart additional security. The French scarf has several indentations, and is termed *traits de Jupiter*, from its zigzag form suggesting a resemblance to sheet lightning. In scarfing bond and wall plates, it is usual to cut about  $\frac{1}{4}$  through each piece on the upper face of the one and the under face of the other, about 6 or 8 inches from the end, transversely, forming what is called a calf or kerf, and longitudinally from the end from  $\frac{1}{4}$  down on the same side, so that the 2 pieces lap together like a half dovetail. These joints are generally spiked, and it is always required that they shall fall in or under a pier, although the supervening weight of the wall and joists renders it impossible to draw them apart, except by tearing the fibres asunder or lifting the weight. Longitudinal joints are employed when the only pressure to be sustained is a vertical one. They are made quite short, as they are designed only to keep the 2 pieces in the same line. A common mode of forming these joints is to divide the end of each piece into 9 squares; then 5 of these being cut away in one piece and the 4 alternate squares in the other, the 2 beams exactly fit each other. The following summary of practice relative to scarfing is given by Barlow in “Tredgold’s Carpentry:” The length of the scarf should be, if bolts are not used—in oak, ash, or elm, 6 times the depth of the beam; in fir (pine), 12 times. If bolts and indents are combined, the length of the scarf should be—in oak, ash, or elm, twice the depth of the beam; in fir, 4 times. In scarfing beams to resist transverse strains, straps driven on tight are better than bolts. The sum of the areas of the bolts should not be less than  $\frac{1}{4}$  the area of the beam, when a longitudinal strain is to be borne. No joint should be used in which shrinkage or expansion can tend to tear the timber. No joint can be made so strong as the timber itself.—Notching is of 2 kinds, square and dovetailed, and is used in connecting the ends of wall plates, and bond timbers at the angles, in letting joists down on beams and binders, purlines, and principal rafters, &c.—Cogging is a species of notching used principally in connecting the beams to wall plates, a shallow notch of the width of the wall plate being cut out of the under surface of the beam, and a similar notch cut on the wall plate to receive the beam; the 2 notches fitting closely, all motion, whether longitudinal or transverse, is prevented. Flooring joists are often connected with trimmers or main joists in the same general manner, except that dovetailed notches are employed instead of square. As there is seldom any great amount of force tending to detach the joists from the trimmers, this form of notch may be amply sufficient; but as a rule, dovetail joints should not be employed in carpentry when the grain of one piece of

wood crosses that of the other, for the shrinkage of timber is much greater across the grain than in the direction of its length; hence dovetails are apt to wear loose after a time, and throw the entire strain upon the pins or bolts, which were originally employed only to assist the joint. When the grain of both pieces runs in the same direction, dovetails can be employed with advantage, since the shrinkage of one piece is counterbalanced by the contraction of the other, which allows the joint to remain firm. Such cases, however, occur more frequently with the joiner than with the carpenter.—Tenoning implies mortising also, both being required to connect 2 pieces by means of a small projection on one, termed a tenon, and a corresponding cavity on the other, called a mortise. Tenons and mortises must exactly correspond in size. They are generally placed at equal distances from one or the other side or edge of the 2 beams to be connected; usually, too, all angles formed in the process of tenoning, whether internal or external, are right angles. Very short tenons, termed joggles, are sometimes used for preventing lateral motion in 2 pieces of timber, as at the connections of a king or queen post with the principal rafters, or with the struts. With the same view, the ends of king and queen posts are generally tenoned into the tie-beams, and the feet of the principal rafters of a roof are also tenoned into the tie-beam. The pressure in this case being very oblique to the surface of the tie-beam, it is usual to employ bolts and nuts, or, what is better, stirrup irons or straps. In forming mortises and tenons, the latter should be made as large and efficient as practicable, with due reference to maintaining the proper degree of strength of the other piece, which by too large a mortise might be materially weakened. To avoid the danger of too great a mortise and too small a tenon, and also of lessening the efficiency of either of the 2 pieces, in consequence of the tenon being placed too high or too low, it is customary to employ a compound called a tusk-tenon for most horizontal bearings of importance, as to joists and binders, to trimmers, beams, girders, &c. The body of such a tenon is a little above the middle of the end, and runs out from 2 to 4 inches, as may be required. Below it protrudes the tusk, and above it the shoulder is cut down at an obtuse angle with the horizontal line, thus giving to the tenon the strength of the whole depth of the timber above the under tusk, and giving it a bearing in a shallow mortise, while a greater depth of the mortised piece than the tusk rests on receives the body of the tenon, thus protecting its comparatively narrow margin from under-pressure.—Pinning and wedging are resorted to when tenons have to resist not only lateral displacement, but strains tending to draw them from their mortises. In pinning, an oak pin or tree-nail or an iron bolt is driven through both the tenon and the sides of the mortise; or, the tenon being cut

long enough mortised piece, the projecting part adopted in connection joists to the girder or In wedging, it is sufficiently long to pass just through the piece; a saw-cut being then made in the projecting part, a small wedge is driven into it, which causes the tenon to expand and completely fill the mortise, so that it cannot be withdrawn. Fox-tail wedging, employed when the tenon does not extend entirely through the mortised piece, is thus performed: The tenon having been exactly fitted to the mortise, 3 cross saw-cuts are made in its end, and small wedges are loosely fitted in them. In driving the tenon down, the heads of these wedges strike against the bottom of the mortise, and the wedges are thus made to enter the tenon, which they expand and cause to fill the mortise. It is usual in scarfing, cogging, and notching to cut in the shoulder with the saw, and to strike out the cheek with the mallet and chisel or with the adze. Tenons are made entirely with the saw. Mortises are usually formed by boring at the ends with an auger, the diameter which is equal to their width, and the intervening portions with a gouge, working this in the direction of the grain of the wood. The ends are squared with a plane, just as broad as the width of the mortise. Pins of wood must be split to fit the mortise, and wedges cut with true bevels for these uses straight-grained stuff must be preferred.—The bearing surfaces of tenons and bearing joints should be as large as possible, and, when practicable, cut at right angles to the direction of the pressure, so that the piece bears longitudinally upon the joint. If the joint is cut on a circular arc, so that the pressure is distributed equally over the bearing surface.—Scaffolding or propping up the walls or floors of a building is also performed by the carpenter, by riving or deafening floors, furring down, bracketing and cradling for plastering, &c. This may be performed either by the carpenter or by the joiner, as less or greater precision is required.—The value of carpenters' work is usually rated by the cubic labor by the square of 100, or by the square of 100, wherever it will admit of being so measured, and it is customary for the cubic labor to be measured as soon as the work is completed, or the joiner and plasterer begin. Bond timber, wood bricks, wall plates, &c. are all reduced to cubic feet of timber, and their price per foot, which is then multiplied upon them. The naked floor is valued by the labor that has been expended upon it, whether the floor is double, or framed; if the floor is party-walls, or stairs; if the floor is wall plates and partitions, and size of the large timbers; if

l nailed to wall plates, and as framed and nailed to binders or common superficial feet are reduced to estimating the labor and nails in setting the floors; then the floor-are rated in cubic feet and without sing is also estimated by the super- for labor and nails, the measure on the common rafters from ridge full description being given of roof and the different tie-beams, straining sills, struts, purlines, pole that may be used in its construction, timated for labor and nails. The bers are then reduced to cubic feet, ments being taken to the extent of there may be, and the whole valued or. The dimensions of bolts, bars, are taken separately and their fuced. Gutter boards and beams d by the superficial foot, and valued the thickness. Centring to vaults y the square, to apertures in the f walls by the foot, and to camber umber. Quartering partitions are r the square for labor and nails, and et for the material. Battening to valued by the square, but the stuff with the labor. If planing has been sometimes happens with beams and ces not to be covered by ceiling, it the superficial foot, and beading or ding by the running foot. Some- rificial amount for labor and nails umber cannot be obtained, and it is ted with the cost of the timber at cubic foot; and in such cases a dis- st be made between different quan- labor employed in framing a roof, is much greater than that required amount of timber used for flooring. f labor, too, depends much on the hardness of the timber. The cost ot of the timber should include the t, and expenses of cartage added. cost of 4 superficial feet of sawing wed as a fair average for the dif- lings; and finally  $\frac{1}{4}$  of this increased waste in cutting and working. A allowance is necessary for scaffold- ting, especially if heavy timbers are nsiderable height. In shoring, as is not consumed, it is usual to se and waste at  $\frac{1}{4}$  of the value of if much cut up, or  $\frac{1}{2}$  if but little m- this in addition to the charge for ding and lowering.

; a sort of thick cloth, used princi- vering the floors of apartments. In a very early period, straw, rushes, coarse materials were used. Im- m this, the rushes were plaited into ich, though homely enough in ap- rved to promote warmth and com- igland, where wool was obtained in a kind of coarse woollen cloth was

often seen upon the floors of the gentry. Yet as late as the time of Queen Mary rushes were strewn on the floor of her presence-chamber; though carpets had long before been introduced from the East. In Egypt their manufacture is traced back to a very remote period; and in Persia and other Asiatic countries the art practised by the hand had attained a high degree of excellence long before it was known in Europe. Purple carpets of great beauty were used at the banquets of the ancient Greeks strewed beneath their couches. The Babylonians adopting the art, ornamented their fabrics with figures of men and strange devices of fabulous creatures. These were imported by the Greeks and Romans; and, from what we know of the fabric, it appears to have been rather of the nature of tapestry, than of what we now call carpets—made by introducing tufts of woollen yarn into a warp stretched in a frame, which are held down by a woof passed over each tuft. Such is the method of carpet-weaving now practised by the Asiatics, the stitches made one by one by the slow and tedious operation of the fingers. The young girls acquire great skill in this work, and their hands and eyes are soon trained to do it with ease and rapidity. But by one of the modern machines 1,000 stitches are sooner made than one by the hand process. In Persia whole families, and even tribes, are employed in carpet-weaving. These carpets are, however, of so small a size, that they are little used. They are purchased by travelling merchants, who, in Smyrna and Constantinople, dispose of them to Europeans. Turkey carpets are imported principally from Ouchak, in the province of Aidin, about 6 days' journey from Smyrna. These carpets are also woven by families, and no large manufactory for them exists. They are in one piece; the patterns are peculiar, and no two are ever made exactly alike. Their chief beauty consists in the harmonious blending of their colors, and in the softness of their texture, rendering them agreeable both to the eye and to the foot. In the process of manufacturing the weaver sits in front of the loom, and fastens to each thread of the warp a bunch of colored yarn, varying the color according to the pattern. The row being completed, he passes a linen weft through the web, and drives it well up, so that all the bunches may be securely fastened. In this way narrow breadths of carpet are made, which are afterward laid side by side, and united, so as to form one large piece. The tufts are then pared of equal length, and being beaten down, the whole presents a smooth, even surface. Rugs are made in the same manner. A superb carpet, composed entirely of silk, was sent from Cashmere to the great exhibition in London. In each square foot it contained as many as 10,000 ties of short lengths introduced by hand. In British India the manufacture of carpets is carried on to a great extent. In Benares and Moorshedabad costly carpets of velvet with gold embroidery are made. Silk-embroidered

carpets are manufactured in various places; the woollen ones principally at Masulipatam. For many years Europe received all her supplies of carpets from the East. The manufacture is said to have been introduced into Europe by the French in the reign of Henry IV. The manufactory now belonging to the French government, and still producing excellent fabrics, was established at Beauvais in 1664 by Colbert, minister of Louis XIV. Another larger factory was at Chaillet, a league from Paris, where the carpets were worked in the manner of the modern Wilton carpet. The first successful operations in England were at Mortlake, in Surrey, to which enterprise James I. contributed £2,676. In the middle of the 18th century the business was much extended in different localities, and reference is made to a premium awarded by the society of arts in 1757 to Mr. Moore for the best imitation Turkey carpets. This kind of carpet was afterward largely produced at Axminster, in Devonshire, made even more expensive than the real Turkey by the substitution of worsted for woollen yarn; but the manufacture ceased here, and in Yorkshire also, many years ago. The other varieties of carpets in use, as the Kidderminster or two-ply, called in this country the ingrain, the three-ply, the Venetian, Brussels, and Wilton, are all made by machinery. The ingrain, made with 2 sets of worsted warp and 2 of woollen weft, consists of 2 distinct webs incorporated into each other at one operation, the warp threads passing from one to the other to bring the required colors to the surface. Each web, however, is a cloth of itself, which, if separated by cutting it from the other, would present a coarse surface like baize. Two colors only are used to best advantage in this kind of carpet, the introduction of more tending to give a striped appearance. The three-ply is also ingrained, the threads being interlaced to produce 3 webs, thus making a fabric of greater thickness and durability with the advantage of greater variety of color. The pattern, however, does not appear in opposite colors on the 2 sides in this, as it does in the two-ply. Great difficulty was experienced in applying the power loom to weaving this fabric; in Europe the idea was wholly abandoned; and in 1839 two-ply ingrains were woven at Lowell, Mass., only by the hand loom, at the rate of 8 yards a day to the loom. At this time Mr. E. B. Bigelow, of Boston, improved the power loom so that he obtained with it from 10 to 12 yards a day, and afterward by still further improvements so perfected the machinery, that the power loom is now wholly used, and with such economy of labor as to have greatly reduced the cost of carpets, and extended their manufacture to meet the increased demand. The inventions of Mr. Bigelow have been so important in this branch of manufacture, as to have given it an entirely new character; and though their full description would be too technical and detailed, a general account of those immediately connected with

the process of weaving should be given. The first operation is to cal, one which and produce a good smooth, even face. The any moment tighten the loose after the shuttle has b make the selvage r measurement that by of the weft threads or is being produced too lo gives more or less force to up; and if he finds that the is getting rough, he regulates warps. In this way, by exercise of skill and judgment, he can approximate, and only approximate, to the production of a good and regular fabric. In the first loom Mr. Bigelow produced, he approximated more nearly than the hand weaver to a perfect match in the figure; and this he effected by taking up the woven cloth by a regular and positive motion which was unerring, the same amount for every throw of the shuttle and beat of the lathe. As the weft threads are not spun regularly, and the weaving in of the warp threads and passing the different colors from the upper to the lower ply or cloth to produce the figures require sometimes more and sometimes less to make a given length, he determined to regulate the delivery of the warps as to tension, thereby throwing the threads of the thickness where it cannot be of into the length, where it would d match of the figures. He accomplished this by suspending a roller on the woven the lathe and the rollers that so that when the cloth was short, which indicated a want of supply of the roller would be elevated, and the tension increase the delivery of more warps, and vice versa, only to prevent the further waste already incurred. The roller, to accomplish its purpose, should have been to the unwoven warps, which is practicable, for when the weft, these must be rigid to no way was apparent to the operative to detect and it up. The warps, moreover, were rolled up on the warp-beam, and so can only be given improvement was afterward made by Mr. Bigelow in the following thread in the usual way, called a mail, attached to a card in the jacquard, and each card had a weight, all the weft threads, and the trap-boards of the loom, moving up and down, and by their movements they catch or (determined by the comb) are required to bring the threads at each operation to

such of them as are not required at that particular operation; and when the two traps are on a level, and all the warp threads fastened with them are in a horizontal line, and not connected with them hang down with suspended weights, the lathe beats up the thread, which lies between the warps that are in a horizontal line, at the same time exerts a force on the weft threads previously woven, and beating them up more closely. Now, as the warp threads are all connected at one end with woven cloth, and at the other with the beam, it follows that those which are hanging down in a bent line will receive a greater proportion of the force of the beat of the lathe than the others; and as all the warp threads in succession take this position, and all receive an equal weight, it follows that each successively receives the same pull at the time the lathe beats up; thus the tendency to irregularity of surface from the varying lengths of warp threads taken up in ingraining is counteracted. The selvage was made smooth and even by a device which regularly gave a pull to the warp thread after the shuttle was thrown. Mr. Bigelow at last, by these improvements and changes which he introduced, brought the loom to an average from 25 to 27 yards a day of two-ply, and from 17 to 18 yards of three-ply carpets. His improved method of producing carpets that will match was afterward introduced and patented in 1845. The same machinery was found to be applicable to the manufacture of Brussels and tapestry carpets, the weaving of which, except by hand, was before generally considered a mechanical impossibility. With the hand loom they were made at the rate of 3 or 4 yards per day; but with the improved loom the production was increased to 20 or 25 yards per day. The carpets, too, were made more exact in their figures, so that these perfectly matched, and their surface was smooth and regular. They surpassed, indeed, in their quality the best carpets of the kind manufactured in any other part of the world. The looms of Mr. Bigelow were introduced into factories built at Lowell, Mass., Thompsonville and Tariffville, Conn., for their use, and others were established at a new place named Clinton, Mass., where, since the year 1849, about 1,000 yards of Brussels carpeting are annually produced by the Bigelow carpet company. This town, 12 m. N. of Worcester, owes its prosperity, and its population of over 8,000, wholly to the various factories established upon the different inventions of Mr. Bigelow. Tariffville, also, now a place of over 2,000 inhabitants, had a population of only 400 in 1840. The carpet establishment there, with a capital of \$900,000, employs from 650 to 800 operatives. Thompsonville presents a similar history.—Brussels carpet is so named from Brussels in Belgium, whence the style was introduced into England in the last century. It is woven upon a ground of linen weft, which is controlled by the worsted threads that are interlaced

with and cover it. The threads are commonly of 5 different colors. In the weaving these run the length of the web, and are so managed that all those required by the pattern are brought up together across the line of the carpet; before they are let down, a wooden instrument called a sword is passed through to hold up the threads; this is replaced by a round wire, which, being at last removed, leaves a row of loops across the carpet. In a yard length the number of successive lifts of the sets of colors required is sometimes as many as 320, each of which forms a row of loops. Four colors must always lie beneath the 5th, which appears on the surface, and thus the carpet, with its linen weft too, is thick and heavy. The Wilton carpet, the *moquette* of the French, differs from the Brussels in the loops being cut before the wire is removed, a groove in the flat upper surface of the wire admitting of their being cut by passing a knife along the surface. The soft ends give the carpet a rich velvety appearance. In the imperial Brussels carpet the figure is raised above the ground of the pattern, and the loops of this are cut, but not of the ground. Various methods have been devised of simplifying the processes of making the Brussels carpet. Mr. Richard Whytock, of Edinburgh, introduced an ingenious plan of using threads dyed of the colors in the succession they would be required. This was done before they were made into the warp, and by a systematic arrangement. By this means a considerable proportion of the threads was dispensed with. His looms are used by one establishment in England to the number of more than 800, producing carpets to the amount of about £500,000 annually. They are known as "patent tapestry and velvet pile" carpets. Another device is to weave the carpet in plain colors, and then print it with rollers or with blocks, after the method of calico printing. On account of the thickness of the fabric, difficulty is experienced in introducing sufficient color without going over the work many times. In doing this, the difficulty is of course increased of retaining each color within its own exact limits. Rollers were first used; but a cheap kind of carpet is now produced at Manchester, England, by block printing. Felt cloths are also printed in colors in this country, and sold to a considerable extent for carpets.—Venetian carpets (which, by the way, were never a production of Venice), are made with a heavy body of worsted warp, which completely hides the woof; this should be an alternate shoot of worsted and linen yarn. The fabric admits of little varieties of design. It is made in narrow widths for stairways and passages.—The patent wool mosaic carpet is a novel manufacture carried on by Messrs. John Crossley and Sons, of Halifax, England. A strong, plain cloth is used as a ground; upon this a pile of warp threads, first arranged over and under parallel strips of metal, which are cut out, leaving the ends like those of a Wilton carpet, is placed

and cemented with caoutchouc. If the threads were of different colors, stripes are produced, or the yarns may have been colored by Whytock's plan, or colored patterns may be obtained by another process in use. This method is principally applied to the production of small articles.—A cheap kind of carpet, of little durability of wear or color, has been extensively introduced into this country the last few years, called the hemp carpet. It is made of hempen threads, the colors running in stripes.—The carpet manufacture has increased rapidly in this country, and in England also within the last few years. In England it is estimated that there are more than 5,000 looms in operation of every description. The business is actively carried on in various parts of the United States. Reference has already been made to the successful enterprises in this branch in Massachusetts and Connecticut. There are also extensive manufactories in different places in New York, New Jersey, and Rhode Island. In Massachusetts alone the value of goods produced in 1855 was \$1,362,819; the capital invested was \$2,264,172, and the hands employed, 1,614, beside 4 manufactories of painted carpeting, 2 of rag carpets, and 2 from which there were no complete returns. In 1845 the value produced in Massachusetts was \$834,322; the capital invested \$488,000, and the hands employed did not exceed 1,034, showing in 10 years an increase in the value manufactured of about \$500,000 in Massachusetts alone. The value of carpetings of all kinds imported into the United States during the year ending June 30, 1857, was \$2,181,290, viz.: from

CARPINI, GIOVANNI DI PLANO, an Italian Franciscan monk and traveller, born about 1210. In 1246 he was sent with a company of several other Franciscans on a mission to the great khan of Tartary, to convert him to Christianity, if possible, or, at least, to induce him rather to employ his arms against the Saracens and Turks than against the Christians. Carpini travelled through Russia and along the shores of the Black sea, and finally reached the court of the Tartar monarch, in some part of the region N. of the desert E. of the Caspian. He remained here a month or more, without apparently accomplishing much, and then set out on

CARPOCRATES, or CARPOCRAS, an Alexandrian theologian, of the Hellenistic Gnostic school, flourished in the 2d century A. D., under the reign of Hadrian; was of a family of Christianized Jews. His theological opinions were, in many respects, similar to those of the Gnostics generally. The fundamental Gnostic idea of a Supreme Being, entirely disconnected with the affairs of the universe, was the starting point of Carpocrates. The demiurgus and the other finite spirits ruling over the material universe, were striving to keep humanity from unity with the Supreme Monad, to which it was constantly tending, on account of its having been an original emanation from him. The preëxistent state of the human soul was, in the Carpocratian system, that period when it had been in perfect unity with the Supreme Monad. The demiurgus and ruling spirits have drawn it away from this sublime union, and endeavored to preserve it in expatriation. One of their methods of accomplishing it is by laws or religious duties and observances, such as self-denial and control of appetites and passions, and general humiliation and penances. Only such a rise above these tyrannous usurpations of the demiurgus and his colleagues, can attain to the true life of the soul. Consequently all religious systems were the devices of the demiurgus, for maintaining his supremacy, and the highest injury to men. This Gnostic Antinomianism developed itself into a practical life of freedom from moral restraint, which both Carpocrates and his son Epiphanes took all pains to justify. The gratification of the appetites and passions became a duty instead of a wrong, and salvation by Jesus was only attainable on the condition of perfect abandonment to an antinomian life. All who thus abandoned themselves were saved, because by confidence in his teachings and example they thus proved themselves, in their convictions at least, freed from the power of the demiurgus. Jesus, they held, was simply a man of superior soul, who, like themselves, had the power to discern the real difficulty, and strength to achieve his own practical redemption, and point the way for others. Carpocrates and his followers rejected the gospels of Matthew and Luke, and the entire Old Testament, as the ingenious contrivance of the demiurgus to keep men in subjection. They also denied the resurrection of the body.

CARPZOV, a family of learned Germans, whose original name was *Carperone*, their ancestors having left Spain in the 16th century on account of religious persecution.—BENEDICT CARPZOV, with whom the distinction of the family commences, was a native of Brandenburg, born

Oct. 22, 1565, died Nov. 24, 1624, and a professor of jurisprudence. He had 5 sons, 4 of whom, Benedict, August, Konrad, and Christian, followed the profession of the father.—The 8th, JOHANN BENEDICT, born June 22, 1607, died Oct. 22, 1657, professor of theology in the university of Leipsic, was a Lutheran, and devoted himself to theology. His 5 sons, David, Johann, Friedrich, Samuel, and August, all gained more or less distinction in theology, jurisprudence, and letters. To the 4th generation the line of renown descends through Samuel to 2 sons, JOHANN, born 1675, died 1739, and JOHANN GOTTLÖB. The latter was a Lutheran theologian and oriental scholar, born in Dresden, Sept. 20, 1679, died at Lübeck, April 7, 1767. He was enabled to complete his knowledge of the oriental languages, while chaplain to the Saxon and Polish embassy to England and Holland. After his return in 1704, he was pastor of several churches, and in 1713 gave public lectures at Leipsic, on homiletic, dogmatic, and pastoral theology, oriental languages, and Hebrew antiquities. In 1719 he became professor of oriental languages at the Leipsic university. In 1730 he accepted the general superintendency and first pastorate of the cathedral of Lübeck, where he died, after enjoying the incy for 37 years. He was an opponent

Moravians, and wrote many works on trinity, and also on the canon of the Scriptures, and correlative subjects.

CARR, DABNEY, a member of the house of burgesses of Virginia, moved and eloquently ported a resolution to appoint a committee grievances and correspondence, in consequence of British encroachments. His resolution was adopted, March 3, 1773. Carr died 2 months afterward. He married a sister of Jefferson, by whom he is described as a man of and judgment and inflexible purpose, mingled with amiability, and of a fanciful eloquence.

CARR, SIR ROBERT, British commissioner New England, was appointed to that office Charles II. in 1664, in conjunction with Nicolls, Cartwright, and Maverick. In 1664, Nicolls and Carr captured New Amsterdam from the Dutch, and called it New York, in honor of the king's brother, the duke of York, afterward James II. Carr forced the Swedes and Dutch on the Delaware into a capitulation. He returned to Boston in 1665, and, in conjunction with his coadjutors, assumed the principal powers of government.

CARRA, a hamlet in the canton of Geneva, Switzerland, remarkable for its rural school for orphans and foundlings, the model on which the other schools for helpless and vagrant children in the Swiss cantons have been formed. It was established in 1820 by M. de Rochemout, on the plan of the Pon school at Hofwyl. The present number of pupils is 26, all boys, there being another establishment for girls in the same canton. The family system is carried out to its fullest extent. The school has been since its commencement under the care of M. J. J.

Eberhard, a pupil of Vehrli. The children are taught all the duties of home and farm life, each in turn having a portion of the household duties assigned to him, till all become familiar with whatever is necessary to the comfort of a peasant's home. They have usually from 1 to 3 school hours a day in summer, and from 3 to 5 in winter. The course of study includes reading, writing, spelling, arithmetic, singing, drawing, and some knowledge of surveying, geography, and natural history. The food and clothing are the same with those of the peasant class of the canton, but the food is carefully and well prepared, and the clothing kept whole and scrupulously neat. Recreation, holidays, and festivals are not forgotten, as being a necessary part of the education of the child, in the estimation of M. Eberhard. Punishments are very rare. The expenses are a little less than \$2,000 per annum.

CARRACCI. I. LUDOVICO, the founder of the Bolognese school of painting, born in Bologna in 1555, died there in 1619. His first master, Prospero Fontana, a Bolognese painter, so little appreciated his capacity that he advised him to adopt some other profession. His slowness of execution was so remarkable that his fellow-pupils called him in ridicule the ox. From Bologna he went to Venice, and studied with Tintoretto. Subsequently he visited Florence and Parma, where he gave much attention to the works of Andrea del Sarto, Correggio, and Parmigiano. The object of these varied studies was presently developed in the establishment of his school of painting, known as the eclectic school of Bologna. In this project he secured the assistance of his cousins Agostino and Annibale, who joined him in Bologna about 1585. In a few years their school was overflowing with pupils, and all the others in Bologna closed. As the head of the academy, Ludovico resided chiefly at Bologna; and his merit is more that of a teacher than of a productive artist. He has left many works at Bologna, including his fresco paintings in the Palazzi Magnani and Zampieri; his series of scenes from the history of St. Benedict and St. Cecilia, in the convent of St. Michel at Bosco; an "Assumption of the Blessed Virgin," one of his best works; and the "Birth of St. John the Baptist." He also painted many "Ecce Homos" and "Pietas." II. AGOSTINO, cousin of the preceding, born at Bologna in 1558, died in 1601. He was the son of a tailor, and when a boy was instructed in the goldsmith's art, whence he became an engraver. At the invitation of his cousin, Ludovico, he embarked in his project for founding a new school of art in Bologna, but first went through a course of studies at Bologna, Rome, Parma, and Venice. To Agostino were assigned the most important and laborious duties. He prepared treatises on architecture and perspective, lectured on anatomy, and suggested subjects for composition, drawn from history or fiction. He also proposed and awarded prizes for designs, celebrating the vic-

CARRAGEEN, or IRISH MOSS, a marine plant, *Chondrus crispus* (see ALGÆ), which grows upon the rocks of the coasts of Europe, particularly of Ireland, and is said also to be a native of the United States. It is collected for the preparation of a light and nutritious food for invalids, and is particularly recommended in pulmonary and scrofulous affections, dysentery, diarrhoea, &c. It is prepared by macerating it in cold water, in which it swells without dissolving, and which removes the taste of extraneous matters mixed with it. It is then boiled in water, of which 3 pints are used to the ounce of moss. Milk instead of water makes a more nutritious preparation. It dissolves and gelatinizes, and the jelly is flavored with lemon juice, and sweetened with sugar.

CARREL, NICOLAS ARMAND, one of the founders of the Paris journal, *Le National*, born May 8, 1800, at Rouen, died July 24, 1836, at St. Mandé, near Paris. The son of a worthy merchant, he was educated at St. Cyr, and entered the army as sub-lieutenant; secretly participated in the Bédfort conspiracy in 1821, but eluded

vicision. His political opinions became known on the occasion of the outbreak of the Spanish revolution. A letter he had written to the Cortes came into the hands of his colonel, when he resigned his commission, and entered into the foreign legion in Spain. When the French army invaded the peninsula, Carrel was made prisoner, and arraigned before a French court-martial, who declared their incompetency; but on an appeal to the court of cassation, he was sent before another tribunal, by which he was sentenced to death, as having carried arms against his own country. On account of some informality, the verdict was not carried out; and Carrel was tried before a 3d court-martial at Toulouse, which acquitted him. He was now engaged for a few months

as amanuensis to the historian Thierry; when he wrote 2 essays on the history of Scotland and of modern Greece, and a biographical notice of Paul Louis Courier, the French pamphleteer; he was also editor of the *Revue*

*ricaine*, a short-lived monthly, and an occasional contributor to several leading opposition papers, such as the *Constitutionnel* and the *Libre*. But he did not gain much literary reputation until the appearance of his *Histoire de la contre-révolution en Angleterre*, which was favorably received. With a view of finding an outlet for his political opinions, with Thiers and Mignet he founded the *National*. Thiers,

being the oldest and the best known of the 3, was the leading editor, while Carrel wrote chiefly for the literary department of the paper.

The *National* greatly contributed to bring about the revolution of 1830; but while, on the first signs of a collision, Thiers left Paris, and Mignet kept still, Carrel came out with his wonted audacity, and participated in the battle. When it was over, he was sent on a mission into the western departments; his wise measures and personal influence contributed to maintain tranquillity there. During his absence he had been nominated prefect of the department of Cantal; he declined the appointment, and went back to the *National*, of which he now assumed the chief editorship. Under his control, and chiefly by his contributions, the *National* became a most vigorous and eloquent journal, and gave to the republican party a standing which it never had before. The frankness and boldness of his course drew on him the anger of the government, but the measures taken against him, however trying, could not damp his ardor. He was the first to vindicate the memory of Marshal Ney before the court of peers; and his generous temerity would have been severely punished, if he had not been supported by Gen. Excelmans, himself a peer of France. His quickness of temper, enhanced by exaggerated chivalric notions, involved him in several duels. Previous to the revolution of July, he had espoused a quarrel brought about by an article from the pen of Thiers, and fought for his colleague. In 1838, threats having been uttered against the opposition by the legitimists, Carrel came out as the champion of the former, and had an encounter with Roux de Laborie, in which both were wounded, Carrel very severely. This circumstance elicited many evidences of the admiration he had won even in the ranks of his political opponents.—Three years after, Émile de Girardin challenged him; they fought at Vincennes, with pistols; Girardin was slightly wounded in the thigh, and Carrel received a ball in the abdomen. He was taken to St. Mandé, to the house of one of his friends, and after 2 days' suffering breathed his last. On the news of his wound spreading through Paris, crowds of citizens flocked to St. Mandé, and the deepest sympathy was manifested among all classes; his death was considered a public calamity. A new edition of his works was published in Paris in 1858, in 6 volumes.

CARRENO MIRANDA, JUAN DE, a Spanish painter, born in 1614, died in 1685. As a colorist, the Spaniards rank him with Titian and Vandyke. His principal paintings are a "Magdalene in the Desert," at Madrid; a "Holy Family," at Toledo; and a "Baptism of our Saviour," at Alcalá de Henares.

CARRER, LUIGI, an Italian poet, born in Venice in 1801, died Dec. 23, 1850. He officiated as professor of philosophy at Padua, from 1830 to 1833, when he went to Venice, where he conducted a literary journal for 9 years, during which time he was also appointed by the municipal council professor in the school of arts and sciences, and director of the museum.

Here he published several works, the most popular of which is the "Ring with Seven Diamonds" (*L'Anello di Sette Gemme*), a poetic description of the history and customs of Venice. His lyric poems are his best productions.

CARRERA, the name of 3 brothers who distinguished themselves as revolutionary leaders in Chili against Spain, during the war of independence at the beginning of this century. —José MIGUEL, the eldest and most celebrated, was captured by the Spaniards and beheaded at Mendoza, Sept. 1, 1821; the 2 younger brothers were beheaded at Mendoza on the same day, April 8, 1817, 5 months after their capture.

CARRERA, RAFAEL, ruler of Guatemala, born in the city of Guatemala in 1814, of mixed Indian and negro blood. In 1829, when Morazan was president of the federal government, Carrera became a drummer-boy in the regiment of Col. Aycumena. Subsequently he retired to the village of Metaquascuintla, where he married a woman of singularly energetic character, his constant companion throughout his subsequent career. At that time the property and privileges of the church were assailed by certain partisans of immediate reform, while the Indians were generally wedded to the system of laws familiar to them for nearly 8 centuries, but which was about to be supplanted by Livingston's Louisiana code. Great discontent was thus excited among them, when an insult offered to his wife by a government officer roused Carrera to action. Bent on vengeance, he placed himself, in 1837, at the head of a band of insurgent mountaineers. Enlisting in a remarkable degree the sympathies of the Indian population, the rebellion made rapid strides. Strengthened at every defeat, he was in turns courted and caressed by Barrundia and other members of the 2 opposite factions which divided the government. In Feb. 1838, he occupied the city of Guatemala with 6,000 Indians, and young as he was, he succeeded in restraining his followers from the anticipated pillage and massacre. Some accommodation among the conflicting parties now followed, and Carrera, in the general terror, was sent to Meta, a neighboring district of the interior, in an official capacity, to which a salary was attached. On April 18, 1839, he again occupied the capital, which he has since held. Ruling at first as general-in-chief, he was elected, March 21, 1847, to the presidency of Guatemala. In Feb. 1851, with only 1,500 men, he defeated the combined forces of San Salvador and Honduras, since when peace has been preserved. He was re-elected Oct. 19, 1851, as president for life. In the earlier part of his career he was regarded as the enemy of order and civilization. As the leader of an unbridled mob, in 1838, inflamed with political animosities, his conduct was naturally controlled by the exigencies of the occasion. But of late years he has verified the opinion, early entertained and expressed by the

CARRIACOU, the largest of the Grenada islands, in the British West Indies, 7 m. long and from 2 to 4 broad. It is well cultivated, and produces good crops of cotton. The town and harbor of Hillsborough are on its W. side.

CARRICKFERGUS, a maritime district of Ulster, Ireland, surrounded by the county of Antrim on all sides save the S., which is washed by the bay of Carrickfergus; area, 26 sq. m.; pop. in 1851, including the town, 8,520. Inland it is in general hilly, but toward the sea the hills gradually disappear, and the country spreads out into an alluvial plain. Oats, potatoes, cattle, and cheese are produced. The fisheries are valuable, and the oysters are famous. A vein of rock salt of remarkable purity and great thickness has recently been discovered. This county belongs to the diocese of Connor, and its entire ecclesiastical income inures to the benefit of a single rector.—CARRICKFERGUS, the capital, pop. in 1851, 2,542, extends about 1 m. along the shore of Carrickfergus bay. It consists of 3 parts: the old or walled town in the centre, the Irish quarter on

and the Scotch quarter on the E. The ruins of the last-mentioned quarter are the work of fishermen, descendants of a colony of religious persecution drove thither from the opposite coast of Scotland in the 17th century. There is an old castle, once very strong, well fortified. The other public buildings of note are the parish church, an anti-structure in the form of a cross, and the town-house, a neat building recently erected. There are 8 flax-spinning mills, a muslin mill, a green, and a linen bleach-mill and in the vicinity, and some trade is also done in tanning, brewing, and distilling.

Sometimes the town was frequently attacked by the Scots. William III. landed here, June 1702.

In the roads opposite the town, the frigate of war Drake was captured by the French, April 24, 1778. The town sends a member to parliament.

CARRICKMACROSS, or MAGHEROSS, a town in the county of Monaghan, Ireland, 10 m. N. N. W. from Dublin; pop. in 1851, 1,200.

The town was granted by Queen Elizabeth I. to the earl of Essex, who built here a castle, the ruins of which are now among the most interesting objects of the place. The castle still remains in the possession of the family.

On the W. side of the town are the ruins of the Shirley family, the proprietors of the district. There are in the town a brewery, malt stores, and a distillery.

CARRIER, JEAN BAPTISTE, a notorious member of the French convention, born in 1756 near Paris, died Dec. 16, 1794, in Paris. Taking part in the national convention in 1792, he advocated the establishment of the revolutionary tribunal, voted for the death of Louis XVI., and a motion for the arrest of Philip the duke of Orleans, and participated in the popular rising of May 31, against the Jacobins.

His revolutionary zeal caused him to be sent to Normandy, then to Nantes, where he arrived Oct. 8, 1793. The western provinces were troubled by civil war, and he devoted himself with ferocious men, ordered numerous arrests, and sent victims to the scaffold on the slightest suspicion. He soon dis-appeared without even a show of trial; without any proceedings, prisoners were murdered by the thousands; and as the guillotine did not afford sufficient means of execution, boats provided with valves were procured, which, after being filled with water, were taken on board hundreds of prisoners, were sunk in the middle of the Loire, where they sank to the bottom with their human cargo.

The first of these dreadful executions was that of 94 priests; several others took place in which women and even children were mingled with men in every stage of life. The unfortunates were confined in a vast building called the warehouse; every day, at night-fall, a list of them were summoned on board the boats, and their death was hidden in the darkness of night. He also invented the so-called "republican marriage:" the victims

were tied in couples, sometimes a man and woman together, then hurled into the river by the executioners; sometimes forced from the boat by the sword or bayonet. Meanwhile numbers of prisoners were also shot in the quarries in the vicinity of Nantes. The convention was for a while kept ignorant of these monstrous scenes; the killing of prisoners here reported as the "translation of culprits." The citizens of Nantes themselves did not dare to denounce him, as they were under the impression that he acted in accordance with the orders of the convention. At last the assembly became aware of the real state of things, and Carrier was recalled by the committee of public safety. Strongly denounced by public opinion, he was arraigned before the revolutionary tribunal, Nov. 25, 1794, and sentenced to death.

CARRIER PIGEON (*columba livia*). This, the *pigeon privé* of Bérillon, the *pigeon domestique* of Brisson, the wild rock pigeon of the British, and the *colommen* of the Welsh, is the stock from which ornithologists generally now agree that the domestic pigeon is derived. "Under this species," writes Mr. Selby, "we include not only the common pigeon, or inhabitant of the dovecot, but all those numerous varieties, or, as they are commonly called, races of domesticated pigeons so highly prized, and fostered with so much care and attention by the amateur breeder, or pigeon fancier; for, however diversified their forms, color, or peculiarity of habit may be, we consider them all as having originated with a few accidental varieties of the common pigeon, and not from any cross of that bird with other species, no signs or marks whatever of such being apparent in any of the numerous varieties known to us. In fact, the greater part of them owe their existence to the interference and art of man; for, by separating from the parent stock such accidental varieties as have occasionally occurred, by subjecting these to captivity and domestication, and by assorting and pairing them together as fancy or caprice suggested, he has, at intervals, generated all the various races and peculiar varieties, which, it is well known, when once produced, may be perpetuated for an indefinite period, by being kept separate from and unmixed with others, or what by those interested in such pursuits is usually termed 'breeding in and in.' Such also, we may add, is the opinion of the most eminent naturalists as to their origin; and it is strongly insisted on by M. Temminck, in his valuable *Histoire générale naturelle des pigeons*. Indeed, the fact that all the varieties, however much they may differ in size, color, or any other particulars, if permitted, breed freely and indiscriminately together, and produce a progeny equally prolific, is another and a convincing proof of a common origin; for it is one of those universal laws of nature, extending even to plants, and one which, if once set aside and not enforced, would plunge all animated nature into indescribable confusion, that the offspring produced by the intercourse of different spe-

cies, that is, distinct species, is incapable of further increase." The varieties of this bird, produced under the fostering hand of man, the tumblers, croppers, jacobines, runts, spots, turbits, owls, nuns, &c., would fill a volume; the carrier, however, demands especial notice. The carrier pigeon is a bird larger than the common pigeon, measures about 15 inches in length, and weighs about 1½ lb. The neck is long, and the pectoral muscles very large, indicating a power of vigorous and long-continued flight. An appendage of naked skin hangs across its bill, and continues down on either side of the lower mandible. According to its size and shape the amateurs of carrier pigeons estimate the value of the bird. They consider those pigeons the best that have the appendage rising high on the head, and of considerable width across the bill, and that are also distinguished by a wide circlet round the eyes, destitute of feathers. The instinct which renders this bird so valuable is its very strong love of home, which is, in some degree, common to all the domesticated varieties. The mode of training them in Turkey, where the art is supposed to be carried to the greatest perfection, is this: The person who has the charge of rearing and training them watches for the arrival of the young pigeons at the full strength of wing, and then takes them in a covered basket to a distance of about ¼ mile from their home; they are then set at liberty, and if any of them fail in returning home from this short distance, they are considered stupid, and are rejected as valueless. Those that return home are then taken to greater distances, progressively increased from 2 to 1,000 miles, and they will then return with certainty from the furthest parts of the kingdom. In England, it is usual to keep these birds in a dark place for about 6 hours before they are used; they are then sparingly fed, but have as much water given them as they will drink. The paper on which the message is written should be carefully tied round the upper part of the bird's leg, but so as in no wise to impede its flight. In older times, it appears, from an English ballad, and from a line in Tasso, that the original way of suspending the despatch was from the wing, or round the neck, but the above method is that now adopted. The antiquity of the application of these birds to the purpose of bearing intelligence to distant parts or persons, and the perseverance with which some varieties (that which is named, from its peculiar fitness, the carrier, more especially), when well trained, will return from long distances, is well known; but it is not known when, or by whom, the pigeon was first applied to this purpose. "The same faculty which in comparatively modern days was degraded to giving notice to the authorities that the finisher of the law had done his duty, on Tyburn hanging days—Hogarth's graphic record of the custom will occur to most—which afterward sank to being the bearer of the news of the

prize ring, and nowadays conveys the price of stocks to and from the continent, or brings the first intelligence of the winner of the Derby, kept Hirtius and Brutus constantly informed of each other's designs and movements, as Antony the besieger felt to his cost. In vain did he spread his nets, and try every stratagem to baffle these couriers of the air; he had the mortification of seeing them going and returning every morning over the beleaguered walls of Martina. Anacreon's dove" (see his ode *Εἰς Ἰλαρὴν*) "was employed on a more gentle mission; and Taurosthenes sent one decked with purple to his happy father, in the island of Ægina, with the news of his victory at the Olympic games, on the day of the pigeon's arrival. We have the authority of Sir John Mandeville—he who made his way to the border of China, in the reigns of the second and third Edward—that the Asiatics used them for the same purpose as the Romans. During the crusade of St. Louis, they were so employed; Tasso presses them into service in the siege of Jerusalem," making Godfrey defend one when attacked by a falcon; and Ariosto makes the castellan di Damiata spread the news of Orrilo's death by a messenger dove. "The rapidity of the flight of some of the species," says Mr. Broderip, "is almost incredible. The passenger pigeon has been shot in the neighborhood of New York, with its crop full of rice, which the bird could not have procured nearer than the rice fields of Georgia and Carolina. Audubon, who relates this startling, but, I believe true, fact, observes that, as their power of digestion is so great that they entirely decompose food in 12 hours, the birds which were killed in the neighborhood of New York must have travelled between 300 and 400 miles in 6 hours. The passenger pigeon would thus, as Audubon observes, be enabled, were it so inclined, to visit Europe in less than 8 days." With all deference to Mr. Audubon's opinion, however, something more than inclination would be required by the bird to enable it to pay the visit intimated; for, rapid as are its powers of digesting food, equally rapid is the failure of strength when deprived of food; and a bird can no more endure many consecutive hours of total privation of sustenance than a man can support as many consecutive days; so that unless the passenger pigeon were to take a walk of rice under his wing, he would have but little chance of reaching the term of a 8 days' journey, unless he should calculate on stopping en route, and taking a meal on board one of the mail steamers, as at a half-way house, and on finding a second on which to roost, since the pigeon is not nocturnal.—The ordinary rate of the flight of carrier pigeons is not generally held to exceed 30 miles an hour. Wagers have been laid to determine the rate of a carrier pigeon's flight. "In 1808, a young man in the borough undertook that his pigeons should fly 85 miles in an hour. Three were thrown up at 5 o'clock in the evening beyond Tunbridge Wells, and arrived at their owner's res-

hence in 53 minutes, thus beating time by 7 minutes. A gentleman laid a wager on this event, and he sent a pigeon to Bury St. Edmund's, with a request that the bird, 2 days after its arrival there, might be thrown up as the clock struck 9 in the morning. This was done, and at 11½ o'clock that morning the pigeon was shown at the Bull inn, Bishopsgate, into the loft of which respectable establishment it had entered, having made its way to that point in London in 2½ hours, and having traversed 72 aerial miles in that time. When the annual trial of the prize for the best carrier pigeons was decided at Ghent on June 24, 1838, 24 birds, which had been conveyed from that place, were thrown up at Rouen at 55 minutes past 9 o'clock in the morning. The distance is 150 m., be the same, in lawyer's phrase, more or less, and the first pigeon arrived in Ghent in 1½ hour; 16 came in within 2½ hours, and 8 in the course of the day; 4 were lost. If this statement be correct, the first bird more than trebled the usual rate of a carrier pigeon's flight, and covered at least 90 m. in the

It is said that wild ducks have been known to perform this rate in passing head-

The education of carrier pigeons is entirely progressive; the distance flown being gradually and slowly increased from ¼ mile up to 20 or 30 miles. When the bird is able to accomplish this, he may be trusted to fly any

distance overland, within the limits of physical power. The younger the bird is, if it have strength to fly well, the greater is the chance of educating it to be a good bearer of a despatch.

This drilling be not commenced early, birds of the best breed cannot be trusted. When taken down, the bird rises, and when it has reached a good height, will at first fly round and round, and then make off, continuing on wing without stop or stay, unless prevented,

until its well-known home is reached. A word to the wise: One should never throw up his bird in a fog or hazy weather, or 'tis ten to one

that it will not be seen again. The spiral flight, when the birds are thrown up, is evidently a flight of observation, and when they catch sight of any well-known landmark, away they go homeward. But they are lost if no such objects are in sight. Thus pigeons, when loosed from a balloon at a great height, have, after flying round and round, returned to the balloon, for want of objects to guide them in their homeward flight. And yet there is on record a wonderful instance of their return to their domicile under circumstances of great difficulty, to say the

least of it, as far as guide marks are concerned. The battle of Solebay was fought May 28, 1672.

John Jarleton was a volunteer on board the London man-of-war in that engagement, and he writes that, on the first firing of the London's guns, a number of pigeons, kept in the ship, of which the commander was very fond, flew away. Nowhere were they seen near during the fight. It blew a brisk gale next day, and

the British fleet was driven some leagues to the southward of the place where the birds forsook the ship. The day after, back came the pigeons, not in one flock, but in small parties of 4 or 5 at a time, till all the birds were safe on board. This unexpected return caused some conversation on board, when Sir Edward Spragge told those who expressed their surprise, that he brought those pigeons with him from the straits, and that when he left the Revenge for the London, all those birds, of their own accord, without the trouble or care of carrying, left the Revenge, and removed with the seamen to the London." This is the more remarkable, since the birds in question, in so far as appears, were not carriers, but only common dove-cot pigeons; and it goes far to corroborate the opinion expressed at the beginning of this paper, that the form, color, and habits, even to those which appear most characteristic and instinctive, of these birds, are merely varieties developed by care and education from accidental occurrences; as this incident clearly indicates the original instinct of returning to an accustomed home, as existing strongly in the original unimproved stock. Nor is it one whit more strange that this educational faculty of carrying should be converted, by a long course of teaching generation after generation, into an hereditary instinct apparently natural in the pigeon, than that the same thing should occur, as it is known to every sportsman that it does, in the pointer and setter, in reference to backing and pointing, naturally, without the breaker's aid.

CARRO, JEAN DE, a champion of vaccination, born in Geneva, Aug. 8, 1770, died at Carlsbad, in Bohemia, March 12, 1857. Taking up his abode in Vienna in 1795, he became celebrated by his efforts in spreading Jenner's system of vaccination as a protection against small-pox, in Germany, Hungary, Poland, and Russia. In 1800 he sent a quantity of virus to Lord Elgin at Constantinople, together with a work of his own, translated into Turkish, on vaccination. The attempts of the English to introduce vaccination into India having been unsuccessful, because the virus had always been deteriorated on the way, Carro was induced to procure the vaccine matter from cows of Lombardy, and send it to Dr. Harford at Bagdad. This retained all its strength, and was the means of introducing the benefits of kine-pox inoculation into India. The Indians consider it to be derived from a sacred cow, to which they give the name of *omurtum*, or immortality. Carro published his "Observations and Experiments on Vaccination," in the French language, at Vienna in 1801-'2. He also published a translation of an English work by J. J. Loy, on the origin of the kine-pox virus. These works are very valuable; and there are some letters written by him in Aug. 1808, on the anti-pestilential nature of the kine-pox matter, which are preserved in the library of the British Museum. He resided at Carlsbad from 1825 to the time of his death, and published there an annual almanac.

also several esteemed publications on the springs of that famous watering place; his last work on the subject, entitled *Vingt-huit ans d'observations et d'expérience à Carlsbad*, appeared in 1858.

**CARROLL**, the name of counties in 14 of the United States. I. An E. co. of N. H., watered by numerous small streams; area about 560 sq. m. Lake Winnipiscogee separates it from Belknap co. on the S. W., and within its own limits are several smaller lakes and ponds. The surface is mountainous and broken, Ossipee mountain and Conway peak being the principal summits. The soil is productive, but much labor is required for its cultivation. In 1850 it yielded 147,715 bushels of Indian corn, 50,467 of oats, 840,278 of potatoes, 84,675 tons of hay, and 570,188 lbs. of butter. There were 25 flour mills, 49 sawmills, 40 churches, and 6,281 pupils attending public schools. The county was named in honor of Charles Carroll of Carrollton, one of the signers of the declaration of independence. Capital, Ossipee. Pop. in 1850, 20,157. II. A N. co. of Maryland, with a hilly surface, and a thin, rocky, but carefully improved soil. It borders on Pennsylvania, is drained by the sources of Patapsco and Gunpowder rivers, and comprises an area of 500 sq. m. In 1850 it produced 265,007 bushels of wheat, 848,008 of Indian corn, 228,179 of oats, and 444,759 lbs. of butter, beside considerable quantities of copper and iron ore, cotton and woollen fabrics, leather, and various manufactures. Two newspapers were published in the county. There were 40 churches, and the public schools numbered 708 pupils. Capital, Westminster. Pop. in 1850, 20,616, of whom 975 were slaves. III. A S. W. co. of Va., area 440 sq. m., bordering on N. C., bounded W. by New or Kanawha river, and extending S. E. to the Blue Ridge. The land, though rough and hilly, is generally fit for cultivation or grazing, and produced in 1850, 182,189 bushels of Indian corn, 11,578 of wheat, 82,847 of oats, 2,715 tons of hay, and 56,178 lbs. of butter. Horses, cattle, and swine are raised, and there are mines of copper, iron, and lead. Grayson sulphur springs, on New river, are much resorted to in summer. Carroll co. was formed from Floyd in 1842. Capital, Hillsville. Pop. in 1850, 5,909, of whom 154 were slaves. Value of real estate in 1856, \$4,282,851. IV. A W. co. of Ga., bordering on Ala.; area, 572 sq. m. The Chattahoochee and the Tallapoosa are the principal rivers. The surface is mountainous, and the soil, which rests chiefly on a granite foundation, is fertile in many parts of the county. One or two gold mines are worked with profit. The agricultural productions in 1850 amounted to 1,243 bales of cotton, 316,871 bushels of Indian corn, 40,803 of oats, and 73,943 of sweet potatoes. There were 840 pupils attending public and other schools. The county was formed in 1826. Capital, Carrollton. Pop. in 1855, 10,526, of whom 1,379 were slaves. Value of real estate

Pop. in 1856,

OLL, CHARLES, of Carrollton, a patriot American revolution, born at Annapolis, Sept. 20, 1737, died Nov. 14, 1832, surviving signer of the declaration of independence. His parents were of the Catholic faith, and in 1745, when he was old, he was taken to the college of Jesuits at St. Omer, where he remained and then went to a college of French at Rheims. After 2 years he went to to study the civil law, and after re- here 1 year, spent the next 2 in Paris, he repaired to London and began the law in the Temple. In 1764 he re- America, and in 1768 married Mary

He inherited a vast estate, the last of royal grants of Maryland, and at the commencement of the revolutionary war was the richest man in the colonies. His would be considered large now, and period, when such fortunes were scarcely was probably little short of 2 millions. He soon began to employ his pen of the colonies against the claims of her country. In 1770-'71 he wrote articles the signature of "The First Citizen," the right of the government to regulate proclamation. About the same time, conversation with Judge Samuel Chase, the remarked, "Carroll, we have the betterponents—we have completely written n." "And do you think," replied Carroll, "writing will settle the question better?" "To be sure," replied Chase; "what

else can we resort to?" "The bayonet," answered Carroll. Some years before the commencement of open hostilities, Mr. Graves, a member of parliament, wrote to Mr. Carroll on the subject of our troubles, ridiculed the idea of our resistance, and said that 6,000 English troops would march from one end of the continent to the other. "So they might," Mr. Carroll observed in his reply, "but they will be masters of the spot only on which they encamp. They will find naught but enemies before them. If we are beaten in the plains, we will retreat to the mountains and defy them. Our resources will increase with our difficulties." When tea was imported into Annapolis, great excitement was created, and Mr. Stewart, the owner, was threatened with violence. Some of his friends called on Mr. Carroll to protect him, or use his influence to do so. He said to them: "It will not do, gentlemen, to export the tea to Europe or the West Indies. Its exportation, contrary to the known regulations of the convention, is an offence for which the people will not be so easily satisfied, and whatever may be my personal esteem for Mr. Stewart, and my wish to prevent violence, it will not be in my power to protect him, unless he consents to pursue a more decisive course of conduct. My advice is, that he set fire to the vessel and burn her, together with the tea she contains, to the water's edge." Mr. Stewart then appeared and soon consented to the proposal, and a few hours afterward the brigantine Peggy, with sails set and colors flying, was given to the flames, to the entire satisfaction of the dense crowd collected. In 1775 Carroll was chosen a member of the first committee of observation that was established at Annapolis; and during the same year he was elected a delegate in the provincial convention. In February, 1776, he was appointed a commissioner with Dr. Franklin and Judge Chase, to proceed to Canada accompanied by the Rev. John Carroll, in order to induce the inhabitants of that country to unite with the colonies. He returned from Canada in June, 1776, and on the 12th presented their report. He found the declaration of independence under discussion, and the delegates of his own state, Maryland, shackled by instructions (given the December previous, and against which he had then contended), "to disavow in the most solemn manner all design in the colonies of independence." On his return he hastened to Annapolis, to resume his seat and procure, if possible, a withdrawal of these instructions. Together with Judge Chase, he labored so assiduously, that on June 28 the instructions were withdrawn and the delegates authorized to join in a declaration of independence. On July 4, 1776, he was appointed a delegate to Congress, and Aug. 2, when the declaration was first signed, he was one of the earliest signers. As he affixed his signature to that immortal compact, a member standing near, knowing his princely wealth, observed, "There go a few millions;" and adding, "However, there are many

Carrolla, and the British will not know which one it is," Mr. Carroll immediately added to his name, "of Carrollton," and was ever afterward known by that title. Mr. Carroll took his seat on July 18, and was soon afterward placed in the board of war. In the latter part of 1776, he was one of the committee to draft the constitution of Maryland, and in December of the same year he was chosen to the senate under the constitution of that state. In 1777 he was re-appointed a delegate to Congress. In 1781 and 1786 he was re-elected to the Maryland senate, and in 1788 a senator of the United States. In 1797 he was again elected to the senate of Maryland, and in 1799 he was appointed one of the commissioners to settle the boundary line between Virginia and Maryland. In 1810 Mr. Carroll retired from public life, and devoted his time to the management of his estate. A man of cultivated mind, captivating manners, liberal and philanthropic in all his views, and proverbially hospitable, his society was eagerly sought by those who resided near him, or in the neighboring city of Baltimore; while those who came from a distance with any proper introduction, met always the warmest welcome. On July 4, 1821, the fact that only 4 of the signers of the declaration of independence were still living, was noticed in many of the newspapers. Of these, William Floyd, of New York, died 80 days afterward. The demise of John Adams and Thomas Jefferson, on July 4, 1826, left Charles Carroll of Carrollton the last surviving signer. In the performance of their obsequies, funeral honors being paid them in Baltimore as in many other cities, Mr. Carroll was chief mourner. On July 4, 1828, after he had passed the patriarchal age of 90 years, in the presence of a vast concourse of spectators and attended by one of the most imposing civic processions ever seen in the United States, he laid the corner stone of the Baltimore and Ohio railroad. He was yet spared for several years longer, and died in the 96th year of his age.

CARROLL, JOHN, an eminent prelate of the Roman Catholic church, and the first archbishop of the U. S., born at Upper Marlborough, Md., in 1735, died Dec. 8, 1815, was educated in the college of St. Omer, and the college of Liège, where he was ordained a priest, and after surrendering his patrimonial estate to his brother, became a member of the society of Jesus. Upon the dissolution of that society in France in 1762, he acted as the secretary of the dispersed fathers, in their remonstrance with the court of France respecting the temporal interests of the order. He then went to England, and was selected by Lord Stourton, a Catholic nobleman, to accompany his son as his tutor in the tour of Europe. During this journey he wrote, for the use of his pupil, a concise history of England. On his return to the continent in 1773, he accepted for a short time a professorship at Bruges, and afterward retired to England,

CARRON, a small river in Scotland, 14 m. long, rising between the friths of Forth and Clyde, and flowing into the frith of Forth, about 8 m. N. of Falkirk. About the middle of its course stand 2 earthen mounds of considerable height, called the hills of Dunipace. It has been supposed that they were made in commemoration of peace between the Romans and the Caledonians, their name coming from *dun*, a hill, and *pax*, peace. They may be merely barrows, however. Not far below them stands the old Roman bridge, supposed to be the scene of a conference between William Wallace and Robert Bruce. About  $\frac{1}{2}$  mile from the stream, near Falkirk, is the battle-ground where the English defeated Wallace in 1296. During the 5th century, many battles between the Romans and the Scots and Picts were fought near this river. The Carron was the boundary of

n empire, the wall of Antoninus runs to and parallel with it for several miles. The village of Carron, on its banks, is famous for its large iron foundery, established

DR. GUY TOUSSAINT JULIEN, a French physician at Rennes, Feb. 23, 1760, died Dec. 18, 1821, in Paris. Having taken holy orders at an early age, he distinguished himself by his active philanthropy in establishing, in his native town, cotton factories, where he provided work for the poor. On the outbreak of the French Revolution he was transported to Jersey.

He established schools for young exiles from France, a Catholic chapel, and charities. In 1796, through the assistance of the government and several noblemen, he founded a college for his young countrymen, a school, and 2 hospitals for emigrants.

In 1814 he returned to France as an exile. He left it, and, with the patronage of Louis XVIII., founded the Marie Thérèse institute for the education of orphans. He wrote many books for the instruction of Christian

CARRONADE, a short piece of iron ordnance constructed at the Carron foundery, in 1779, for the use of the British navy. It was first employed against the United States. The carronades have no trunnions, but are mounted in the middle of the piece, by which they are fastened to the carriage. The bore is small, and the muzzle is scooped out. They are very short and light, there being about 60 or 70 lbs. of the gun to 1 lb. of the solid shot, the length varying from 3 to 4 calibres. The charge, consequently, is small, and the range from  $\frac{1}{2}$  to  $\frac{3}{4}$  of the shot.—Carronades, on their introduction, found great favor with naval commanders, on account of their lightness and insignificant recoil. Great numbers of them to be placed on the small men-of-war of those times. Their advantages appeared proportionably great, and were caused: 1, by a reduced windage,

2, by their great angle of dispar, arising from the thickness of metal around the breech, and the shortness of the gun; and the great amount of metal projected by them rendered their close quarters very formidable. They were employed in the U. S. service about 1800. However, soon discovered that this kind of gun could not compete with longer and heavier guns, throwing their projectiles with full force at low elevations. Thus, it has been found that the common long guns of the service have at 2° elevation, and the same range as the carronade at 3°, the same range as the carronade at 5° (viz., 1,000 yards). And, as the chance of missing increases as the elevation increases, the carronades beyond 1,200 yards and an elevation of 5° is completely out of the question. Long guns may with confidence be used at ranges up to a mile, and even 1,500 yards. This was strikingly exempli-

fied by the 2 contending squadrons on Lakes Erie and Ontario, during the Anglo-American war of 1812-'14. The American vessels had long guns, while the British were mainly armed with carronades. The Americans manœuvred so as to keep just out of range of the British carronades, while their own long guns told heavily on the hulls and rigging of their opponents. In consequence of these defects, carronades have now become almost obsolete. On shore they are used by the British, now and then, on the flanks of bastions and in casemates, where but a short extent of ditch is to be flanked by grape principally. The French navy possesses a carronade with trunnions (*carronade à tourillons*); but this is in reality a powerful gun.

CARROT (*daucus carota*, Tourn.), a member of the natural order *umbellifera*, or parsley family. It is a biennial, bearing seeds on stems 2 to 2½ feet high, in clusters called umbels. It may be seen growing in its wild state in pastures, where it is a great pest. The tap root of the domesticated carrot is raised from seeds sown in cultivated ground, and has long been used in soups and stews, and is a favorite in Germany and France. It is a promoter of good digestion, and is especially valued as a substantial food for horses and other stock. Butter of an excellent quality and bright color can be made by feeding a peck of carrots morning and night to each milch cow. They can be grown at the rate of 500 to 1,500 bushels per acre, and properly managed at a cost of 15 to 20 cents per bushel. In England they are rated at 10 to 28 tons, worth £1 sterling per ton at least. In our markets they bring \$1 to \$1.50 per barrel of 2½ bushels; in bulk for feeding, about 40 to 50 cents per bushel. Soil not capable of producing 500 bushels per acre should never be used for carrots. The best soil is a deep dry loam, rich from previous manuring. The carrot germinates slowly, requiring about 8 weeks before it appears above ground. This slow growth allows the weeds time to start, and makes culture more expensive. To avoid this difficulty, it has been the practice with many to drill radishes, mustard, or oats with them, to mark the row at an early period so as to allow the spaces between the rows to be cleaned, even before the plants are up. Some growers place the seed in a bag, bury it in the earth until it begins to swell and show signs of sprouting, when it is rolled in plaster and planted. The amount of seed required is 2½ to 4 lbs. per acre, depending on nearness of drills; if radishes are sown with them, an equal bulk will be required. Early carrots for house use are sown as soon as the soil is fit to receive the seed; "early horn" is the best variety. Field carrots do better, sown from May 10 to June 10. The large Altringham, white Belgian, and long Orange, are the choicest varieties. The latter does not yield as much as the others, but is of finer quality. The white Belgian carrot gives the least trouble in field culture. In England, carrots are

best grown on ridges, but in our warm climate flat culture is to be preferred. In gardens they are sown in drills 15 to 20 inches asunder, and cultivated by hand. In the field they are planted from 24 to 30 inches apart, grown more thickly in the drill, and tilled by horse power. The land is deeply ploughed, subsoiled, smoothly harrowed and rolled. The seed is sown from a drill barrow at a depth of  $\frac{1}{2}$  to  $\frac{3}{4}$  of an inch. Some drilling machines sow a special manure with the seed, which is advantageous in giving the plants an early start. Should any manure be required, it would be advisable to use soluble special manures, made with regard to the wants of the plant and the deficiencies of the soil. The best Peruvian guano, mixed with many times its bulk of muck or charcoal dust, will answer a good purpose, if ploughed in the soil before planting; 800 lbs. to 500 lbs. per acre will be required for a good dressing. Soluble superphosphate of lime, with about  $\frac{1}{2}$  its weight of guano, probably forms one of the best general manures for carrots. Ten bushels of common salt per acre will add to its value; and on most soils 25 or 50 bushels of unleached wood ashes dressed over the surface separately from and after the other manures, so that they will not come in immediate contact with the ashes, will increase the yield. After-culture consists in frequent stirring of the soil with Knox's horse-hoe or root-cleaner, or other similar instrument, which cuts close to the plant, and demolishes all weeds in spaces between the rows. In November the crop is lifted, by running a subsoil lifter close to a row of carrots at full depth, say 10 to 20 inches; this will loosen the whole soil, and the roots may be readily pulled, the tops removed with a knife, fed to the cattle, or left on the ground to be ploughed under for manure, while the roots are stored in a cool cellar, where an even temperature just above freezing is maintained; or they may be pitted in long narrow piles in the field, covered with 2 or 3 inches of long rye straw and several inches in depth of earth, leaving straw chimneys to ventilate the pits. When fed to cattle, they should be washed in clean water, and cut in thin slices, and given alone or with other food. The meal for fattening cattle should be sprinkled over carrots, if rapid improvement is desired.

**CARROUSEL**, a chariot race, or a magnificent entertainment given by princes or other great personages, who appeared clothed and armed in the manner of ancient cavaliers. Tertullian ascribes their invention to the goddess Circe, and says that they were instituted in honor of the sun, and consisted at first only of chariot races; whence the name has been derived from the Latin *carrus solis*, the chariot of the sun. Carrousels were common among the Goths, Moors, and Italians, and were introduced into France under Henry IV. They succeeded the jousts and tournaments, in one of which Henry II. had lost his life, but since the time of Louis XIV. have passed out of fashion.

The pl rounded with and principal fable or history was representation. The the court of the Louvre in 4 elements, fire, air, earth, and water, cavaliers were attired in the characters of fauns, Mercury, Neptune, Orpheus. Louis XIV. a carrousel was celebrated at the Tuileries, in which 4 nations were represented. The king himself took command of the French, and the Persians, Turks, and Muscovites were commanded by the noble lords. The combats were formed, and various exercises and combats succeeded. The combatants broke lances with each other, and finally against a wooden figure.

**CARSON, CHRISTOPHER**, popularly known as **KIT CARSON**, an American mountaineer, trapper, and guide, born in Madison co., Ky., Dec. 24, 1809. While yet an infant his family emigrated to what is now Howard co., Mo. At 15 years of age he was apprenticed to a saddler, with whom he continued 2 years, when he joined a hunting expedition. The next 8 years of his life were passed as a trapper, which pursuit he relinquished on receiving the appointment of hunter to Bent's fort, where he continued for 8 years more. At the expiration of this time, he made a short visit to his family, and on his return chanced to meet Col. the Lieut. Fremont, by whom he was engaged as guide in his subsequent explorations. In 1847 Carson was sent to Washington as bearer of despatches, and received an appointment as lieutenant in the rifle corps of the U. S. army. In 1853 he drove 6,500 sheep to California, a difficult but successful undertaking, and on his return to Taos was appointed Indian agent in New Mexico.

**CARSTAIRS, WILLIAM**, a Scottish divine, born in 1649, died in 1715. He was educated at Edinburgh and Utrecht, and devoted himself warmly to the prince of Orange. He was minister of an English church at Leyden; but returning home, he took offence at the conduct of the Episcopal party, through whose influence he was arrested, after which he retired again to Holland. He was brought back on a charge of having been accessory to the Rye House plot, and put to the torture. He was dismissed, with the king's pardon, and again went to Holland, where he rose still higher in favor with the prince. He contributed much, as King William's chaplain, to the establishment of the Presbyterian government in Scotland. During the reign of Anne he still retained his chaplaincy. In 1704 he became professor of divinity at Edinburgh, and was 4 times moderator of the general assembly.

**CARSTENS, ASMUS JAKOB**, a German painter, born at St. Jürgen, near Schleswig, May 10, 1754, died May 26, 1798. He was a miller's son, but received a superior education from his mother. He had a youthful passion

ting, but after his mother's death was in a mercantile house. After quitting her, he went to Copenhagen, where he lived on for 7 years, supporting himself by painting, at the same time working at a historical picture on the "Death of . . ." He went to Italy after finishing this and lived at Lübeck for 5 years, toiling in obscurity, when he was introduced by the Lübeck to a wealthy patron, by whose aid he went to Berlin, where the merit of his "The Angels," a colossal picture, covering 200 figures, gained him a professorship in the academy of fine arts. Two years' residence in Berlin enabled him to accomplish his wish to go to Rome, and study the works of Michel Angelo and Raphael. His best works were designs in aquarelle, and painting in oil; he rarely painted in oil. His cartoons at Weimar have been engraved by Müller.

Pindar, Aristophanes, and Dante supplied him with his best subjects; and among the writers who endeavored to infuse a classic spirit into the fine arts of the 18th century, he occupied a prominent position.

**CARTAGO**, a town of Costa Rica, Central America, stands on the river of the same name at the base of the volcano of Cartago. It was formerly the capital of Costa Rica and of great commercial importance, but in both respects has given way to the present capital, San José. In 1841 it was almost entirely ruined by an earthquake, which destroyed nearly 3,000 persons and 7 out of the 8 churches. The population was very numerous, is supposed to have been reduced down to 5,000, and by some authorities to 3,000.

**CARTAGO**, a town, pop. 5,500, on the Vieja river, in the state of Cauca, New Granada. It has straight streets, a spacious square, a cathedral, 2 parish churches, and a good school. The climate is dry and healthy, but very hot. Sugar-cane is cultivated with advantage in the vicinity; the surrounding hills contain numerous minerals of various kinds are found in abundance. Cattle, live pigs, fruits, coffee, cocoa, and sugar are the principal articles of trade. **CARTER, THOMAS**, an English scholar, born at Stratford-upon-Avon, Warwickshire, April, 1686, died at Readington, Berkshire, April 1, 1754.—He studied at Oxford and Cambridge, received holy orders, and was appointed reader of the Abbey of Bath. A sermon which he preached in 1714, in which he endeavored to vindicate Charles I. with regard to the Irish rebellion, engaged him in a controversy with Dr. Burnet and led to his first publication, entitled "The Irish Massacre set in a Clear Light." On the accession of George I. he declined taking the oath of allegiance, and therefore relinquished his ecclesiastical office. In 1715 he was suspected of being implicated in the rebellion, and fled to conceal himself in the house of Mr. Badger at Coleshill. Having officiated as curate in that town for a short time, he was appointed secretary to the famous Bishop Atter-

bury. In 1722 he was again strongly suspected of being concerned in the bishop's conspiracy. A reward of £1,000 was offered for his apprehension, but he escaped into France and remained there for a number of years under the assumed name of Phillips, until Queen Caroline obtained permission for him to return to England. In 1744 he again gave umbrage to the government, and was arrested in consequence of some apprehensions from the pretender, but soon discharged.—His principal works consist of the chief materials for an English edition of De Thou and Rigault, in 7 vols.; a "Life of James, Duke of Ormond," and a "History of England." The latter was published by subscription. A note in the 1st volume stating that some person had been healed of the king's evil by the touch of the pretender impaired the popularity of the work. Mr. Carte, however, prosecuted his undertaking with undiminished zeal, but did not live to complete the 4th volume, which appeared in 1755. It was to have been carried down to the restoration, but does not go beyond the year 1654.

**CARTE-BLANCHE** (Fr. white card), a blank paper with a signature, and sometimes a seal, at the bottom, intrusted to a person to be filled up at his discretion. The term is generally used in the sense of unconditional power given to a person to act as he judges best.

**CARTEL**, a writing or agreement between hostile powers for some mutual advantage, such as the exchange of prisoners. In France and Italy it also means a challenge or letter of defiance, but in England and America this sense is obsolete.—A cartel ship is a vessel used in exchanging prisoners or carrying proposals to an enemy.

**CARTER**. I. A N. E. co. of Tenn., bordering on N. C.; area estimated at 850 sq. m.; pop. in 1850, 6,296, of whom 858 were slaves. It occupies some of the highest ground in the state. A range called Iron mountain, covered with timber and rich in mines of iron, extends along its south-eastern border. Watauga river and other streams supply the county with excellent water-power, which is extensively employed in iron works. The valleys are highly productive, and the harvest in 1850 amounted to 178,541 bushels of Indian corn, 94,351 of oats, 19,307 of wheat, and 76,656 lbs. of butter. Capital, Elizabethtown. II. A N. E. co. of Ky.; area about 550 sq. m.; pop. in 1850, 6,241, of whom 257 were slaves, separated from Virginia on the E. by Big Sandy river. The surface is hilly and broken. The soil near the rivers is tolerably fertile, but in other places unfit for cultivation. The mineral wealth of the county, however, is considerable, iron ore and stone coal being found among the hills in great quantities. The agricultural productions in 1850 were 279,777 bushels of Indian corn, 86,409 of oats, and 15,674 lbs. of wool. There were 4 churches, and 696 pupils attending public schools. There are salt springs of some value near Sandy river, and the grazing lands main-

tain numbers of cattle. Organized in 1888, and named in honor of William G. Carter, a member of the state senate. Capital, Grayson.

CARTER, ELIZABETH, an English authoress, born at Deal, in Kent, Dec. 16, 1717, died in London, Feb. 19, 1806. She translated Epicurus, and also wrote some poems, and numbers 44 and 100 of the "Rambler." Her poetic works exhibit much tenderness, simplicity of sentiment, and expressive sweetness. She was never married.

CARTER, JAMES GORDON, an American educationist, born at Leominster, Mass., Sept. 7, 1795, died at Chicago, Ill., July 22, 1849. Having by his own exertions fitted himself for college, he entered at Harvard in 1816, in the same class with the celebrated mathematical writer Warren Colburn; it was during their college course that Colburn projected the little work which has attained such an important position in American education, the "First Lessons in Arithmetic," and its leading features were all discussed with Carter and arranged before they graduated. Mr. Carter took his degree in 1820, and immediately devoted his attention to teaching at Lancaster, Mass., in which employment he continued except for a short interval until 1830. In 1823 he contributed to the "Boston Patriot" a series of essays on education, which were subsequently published in a collected form, under the title of "Carter's Essays on Popular Education." In 1824 he followed these by "Letters to the Hon. William Prescott, LL.D., on the Free Schools of New England, with Remarks on the Principles of Instruction." In the essays, he first developed the idea of a seminary for teachers, or, as it is now generally called, a normal school. There is no reason to believe that Mr. Carter knew of the existence of such schools in Prussia, though, in fact, they had existed there for some years. In 1824 he went to Boston and took charge of the "U. S. Review," which had at that time been united with the "Literary Gazette." In 1827 he presented a memorial to the legislature of Massachusetts, praying for aid in the establishment of a seminary for teachers with a model school attached. The proposition was not adopted, but the town of Lancaster appropriated a portion of land and the use of an academy building to the purpose, and Mr. C. purchased several dwelling-houses for the accommodation of his teachers and pupils, procured assistants, and opened his school. In a few months he was compelled to relinquish his project as a public enterprise, and confine himself to the reception of pupils into his own house, many of whom afterward became successful teachers in Massachusetts and elsewhere. In 1830 he assisted in the organization of the American institute of instruction, of which he was for many years an active member and officer. His lectures before that body in 1830 and 1831 are among the most valuable contributions to its transactions. From 1835 to 1840 he was a member of the legislature, 8 years in the house and 2 in the senate. As chairman of the

committee on important granting and instruction; "providing establishments," and foresight; a bill for the superintendent of common for the establishment of professional education of teachers made an unsuccessful effort to secure appropriation of one-half the U. S. falling to the state for the inaries for the education of teachers, in the same session a bill drafted by the board of education, houses. Gov. Everett appointed the first member of the board.

CARTER, NATHANIEL H., an American author, born at Concord, N. H., Sept. 17, 1776, died in Marseilles, Jan. 2, 1830. He was educated at Exeter academy and Dartmouth college, and in 1811, after graduating, became a teacher at Salisbury, N. H., and subsequently at Portland, Me. In 1817 he was elected professor of languages in the university created at Dartmouth by the state legislature. This institution was soon broken up by a decision of the supreme court, when he removed to New York, and became editor of the "Statesman," a political newspaper of that city. In 1825 he was engaged by a gentleman of New York to accompany his son on a visit to Europe. He wrote home letters descriptive of his travels, which on his return were collected and published in 2 vols. He passed the winter of 1828 in China; the year he undertook a voyage to Europe, and died soon after his arrival.

CARTERET, a county of North Carolina, bordering on the Atlantic and Pamlico rivers. Area, 450 sq. m.; pop. in 1850, 6,803, of whom 1,200 were slaves. Several long, narrow rivers, one of which is Cape Lookout, separate it from the sea, and Newport News river flows through it. The surface is level, and is occupied by swamps and pine forests. This county produced 40,225 bush. of corn, 54,760 of sweet potatoes, 272 1/2 bush. of flax, 3,940 lbs. of rice, 3,759 lbs. of beeswax and honey. It has 4 sawmills, 12 tar and turpentine distilleries, and the capital invested in manufactures is \$44,400. The number of slaves in 1850 was 1,200. The county was formed in 1722, and is named in honor of Sir George Carteret, one of the first settlers of the land. Capital, Beaufort.

CARTERET, PHILIP, an English navigator, was in the expedition commanded by Wallis, in 1766, on a voyage of discovery to the South seas. He discovered Queen Charlotte's isles, and other isles, 2 of which he called Gower and Carteret. A description of his voyage was given by Dr. Hawkesworth in the introduction to his narrative of Capt. Cook's first voyage.

CARTES, DRA. See DESCARTES.

**CARTESIANS**, the name given to those  
phers who adhere to the system of  
ries.

**CARTHAGE**, the *Carthago* of the Romans,  
of the Greeks; *Carthada* in the Pu-  
a, signifying "new city," in contradis-  
on to the old or parent city of Tyre, found-  
according to the legend by Dido, a Phœnician  
878 B. C. Of the early history, first  
at, and chronology of Carthage, beyond  
that the original colonists were Phœni-  
from Tyre, comparatively speaking, noth-  
is known. To judge by analogy, Carthage  
considerably older, as she was at a very  
period a far more important, city than  
It is said by Herodotus that Hamil-  
king or chief magistrate of Carthage, a  
inian by his father's, but a Syracusan  
r's blood, according to an agree-  
ment with Aærxes, attacked Gelon and Theron,  
Greek leaders in Sicily at the head of  
an army consisting of 80 myriads, or 800,000,  
of Africans, Iberians, Ligurians, Helisycians,  
ardinians, and Corsicans, on the day of the  
attle of Salamis, 480 B. C. Now Herodotus  
was 4 years of age at the time when the bat-  
was delivered; and, as the Carthaginians  
were constantly on the stage during his whole  
life, it is most unlikely that he should have  
called them as bringing forces into the  
which they could not have brought. At  
period, then, Carthage was supposed, by  
contemporary writer, to be capable of tran-  
sporing an army of 800,000 men to the island  
of Sicily, where she notoriously had colonies  
carried on wars, at a time when Rome  
engaged in a struggle for existence against  
a city within 12 m. distance of her capi-  
tal, when she had not a territory of 80 m.  
circumference, which she could call her own;  
not a war ship afloat, for above 2 centuries af-  
ward; not a name that had been entitled to  
consideration, nor a vestige of political im-  
portance, beyond the regions lying immediately  
out the Tiber. That Carthage then had ships  
and commerce is evident, from the existence of  
a commercial treaty, bearing date of the year  
the 1st consuls, preserved by Polybius, which  
one of the most interesting, as it is of the  
most ancient, documents of that character on  
record. By this treaty, which Polybius (iii.  
26) translated from the original brazen ta-  
ble then existing in the capitol, among the ar-  
chives of the ædiles, the language being so ob-  
scure that, in some parts, even the more learned  
among the Romans could only guess at the  
meaning, it was stipulated that the Carthaginians  
should make no conquests and build no forts on  
the Latin coast, even on those parts of it which  
were free; that the Romans may trade freely  
on Carthage herself, and the Libyan coast,  
ward of the Hermæan or Beautiful promon-  
tory, now Cape Bon, and with the island of  
Sardinia, and that on terms of particular com-  
mercial advantage. With Sicily and the inde-  
pendent Phœnician allied colonies Carthage

obtains for the Romans all the privileges which  
she herself possesses, and, in return, the Romans  
are prohibited from entering any port on the  
African coast, E. of the said promontory, which  
forms the eastern boundary of the gulf of Car-  
thage; the object of which prohibition seems  
to have been to exclude them from the rich  
country on the shores of the lesser Syrtis, and  
to preclude them from the direct enjoyment of  
the lucrative trade with Egypt, of which Car-  
thage chose to retain the monopoly.—Of Car-  
thage, from herself, less is known than of any  
other nation of antiquity. She has left no liter-  
ature, no monuments, no traces of her people  
or her language, with the exception of a few in-  
scriptions on coins, and a few verses in one of  
the comedies of Plautus. Even among the  
writers of the nations with whom she carried  
on commercial business, and with whom she  
waged wars, the notices of her polity, of her  
population, of her religion, her manners, or her  
language, are few and far between. Although  
the waters of every sea were white with her  
sails, the shores of every land, hospitable or in-  
hospitable, civilized or savage, were planted  
with her colonies or frequented by her mari-  
ners, no relic of her laws, her language, or  
her blood appears to linger upon earth. Were  
it not for the wars which terminated her  
existence not merely as a nation, but as an ex-  
isting race or people, we should scarcely be  
aware of the existence of a city, the inhabitants  
of which had visited the Western Isles, the  
Canaries and the Cape de Verdes; had braved, if  
they had not crossed, the waters of the terrible  
Atlantic; and had excavated the rocks of Corn-  
wall with their prodigious tin mines. Even of  
the Carthaginians in their wars, we know less  
as a people than of any other which effected  
such wonders, and fill such a space in history  
by their arms. It is, in a word, by the names  
and the deeds of her generals, several of whom  
were among the greatest of antiquity, not by  
the constitution, the composition, or the charac-  
ter of her armies, that we know her. Through  
Aristotle and Polybius, we have learned a little  
of her political system and her government, a  
little of her religion. Of her civic customs, her  
social habits, her domestic institutions, her  
amusements, her industry, with the exception  
of some few hints in relation to her navigation,  
her commerce, and her agriculture, we are  
totally ignorant; posterity has preserved no  
record. Whether she had a literature, we  
know not; whether, even, her own citizens  
served at all as private soldiers in her armies,  
as private mariners in her fleets, is little cer-  
tain. No writer, ancient or modern, has so  
concisely and ably brought together what is  
known of the great commercial republic of  
antiquity, as Dr. Arnold, in his "History of  
Rome," and from the fruit of his researches  
most of what follows is selected. "In the  
middle," he says, "of the 4th century B. C.,  
the Carthaginians possessed the northern coast  
of Africa, from the middle of the greater Syr-

tis to the pillars of Hercules, a country reaching from long. 19° E. to 6° W., and a length of coast which Polybius reckoned at above 16,000 stadia. But, unlike the compactness and organization of the provinces of the Roman empire, this long line of coast was, for the most part, only so far under the dominion of the Carthaginians, that they possessed a chain of commercial establishments along its whole extent, and, with the usual ascendancy of civilized men over barbarians, had obliged the native inhabitants of the country, whether cultivators of the soil or wandering tribes, to acknowledge their superiority. But in that part where the coast runs nearly N. and S. from the Hermæan headland or Cape Bon, to the lesser Syrtis, they had occupied the country more completely. This was one of the richest tracts to be found; and here the Carthaginians had planted their towns thickly, and had covered the open country with their farms and villas. This was their *περίοικος*, the immediate domain of Carthage, where fresh settlements were continually made as a provision for the poorer citizens; settlements prosperous, indeed, and wealthy, but politically dependent, as was always the case in the ancient world; insomuch that the term *περίοικοι*, which in its origin expressed no more than 'men who dwelt not in, but round about a city,' came to signify a particular political relation, theirs, namely, who enjoyed personal freedom, but had no share in the government of their country. Distinct from these settlements of the Carthaginians themselves were the sister cities of Carthage, founded immediately, like herself, by the Phœnicians of Tyre and Sidon, although her fortunes had afterward so outgrown theirs. Among these Phœnician colonies were Utica, more famous in Roman than in Carthaginian history; Adrumetum; the 2 cities known by the name of Leptis, situated the one near the western extremity of the great Syrtis, and the other on the coast, between the lesser Syrtis and the Hermæan headland; and Hippo, a name so closely connected in our minds with the piety and energy of its great bishop, Augustine. These were the allies of Carthage, and some of them were again at the head of a small confederacy of states, who looked up to them for protection, as they in their turn looked up to Carthage. They enjoyed their own laws, and were independent in their domestic government; but in their foreign relations they found, in common with all the weaker states of the ancient world, that alliance with a greater power ended sooner or later in subjection."—In the beginning the Phœnician settlers of Africa occupied their forts and domains by sufferance, and paid tribute to the natives, as an admission that they did not own the soil. Subsequently, like the Europeans in India, the settlers became sovereigns. The natives were driven back from the coasts and confined to the interior. They became mere tillers of the soil, but whether as owners, or merely as tenants, occupants, and cultivators of the land,

cannot be seen. They were not the Roman province to severe taxation on the produce of the soil—war—and to conscription for service in the Carthaginian armies. Another point of similarity between the condition of the domain of Carthage in Africa, and that of the Anglo-India empire, was the numerous race of half-castes sprung from the intermarriage of the settlers with the native women, known as Liby-Phœnicians, or Afro-Phœnicians. It cannot be determined whether these half-castes were to Carthage an element of power or of discord and weakness. It seems, however, that it was a usual practice of the mother city to send out colonies of these half-breeds to the Atlantic coasts of Africa, and probably of Spain also, beyond the pillars of Hercules. It appears, indeed, if the Greek version of the *Periplus* of Hanno may be trusted, that the circumnavigatory voyage so named was undertaken mainly for the settling of 30,000 of these Afro-Phœnicians on the African coast S. of the straits of Gibraltar. So early as the 7th century B. C., the trade of Carthage began with the Spanish seaports, especially with Tartessus or Tarshish, situated on an island lying between the 2 mouths of the Guadalquivir, one of which is now dry, a few leagues to the N. of Cadiz. And in the middle of the 4th B. C., the whole coast of Spain, Atlantic and Mediterranean, was full of Carthaginian trading ports and settlements, but mostly of small size, and of little importance. Sardinia and Corsica, likewise, absolutely subject to Carthage, on the shores of Sicily she had garrisons, trading posts, seaports, and arsenals for the use of their military marine. Among the natives of all these countries, as well as mercenaries from Gaul, Liguria, and the coast of the Adriatic, were recruited the effective armies by which the Carthaginians maintained the quiet of their provinces, the same time pushed their foreign conquests, though at times the safety and independence of the state was threatened, as was proved by the revolt of these terrible and disciplined *condottieri*.—The political constitution of Carthage is said to have resembled that of Sparta, in that it combined the monarchy, of aristocracy, and of democracy. But it is difficult to ascertain exactly how these elements were combined, or which prevailing during the greater period of her power. The aristocratic element prevailed, and it appears to have been an aristocracy of the very wealthy, not of birth; although, to a certain extent, a hereditary nobility furnished the 2 chief magistrates, who were usually called kings and suffetes, w

supreme and nearly despotical executive as being leaders in war, but were by successive usurpations of the to functions and powers not differing from those of the doges of Venice. There was a general assembly, which numerous, probably, as the Roman and represented the aristocracy in from which great assembly was selected council of 100 life members, who chosen, not by the assembly itself, but in batches of 5, which were close confilling up their own vacancies, the of which were also all members both council of 100 and of the great assembly. It is further, that the multiplication of the same hands was a part of the system at Carthage, as it was at Venice, and that the term identical with the Hebrew which is rendered 'judges' in the Scriptures, well as the other principal magistrates, sought their dignities, whether by the of votes or by the payment of money. It is not stated, in such a manner, that office was inaccessible except to the rich. So long as the suffetes and the priests were agreed, it seems that the power of the commons was exceedingly small; they had neither originating powers nor judicial powers; yet, as ample provision was made for the poorer classes, and as the surplus population was always disposed of, profitably and peacefully to themselves, by a system of emigration at the government expense, the Carthaginians remained for many centuries pacified and contented with the constitution of their country, until a very late period, when the progress of her democracy, as indisputably on the increase, was brought to a sudden close by the destruction of Carthage, and the extirpation of the Carthaginian people. It is said by Polybius, during her wars with Rome, the constitution of the city became more and more democratic, and he ascribes the ultimate vicissitude, in some measure, to their stable conservative aristocratic government.—"The language of Phœnicia," says Dr. Arnold, "is cognate tongue with the Hebrew; if it is, as is held by Gesenius and others of authorities, identical with the earliest of the Old Testament, and varying from it more than does the dialect of the later Hebrew writers. It is evident, however, from the fact that the Carthaginian tongue seems to have been nowhere studied by the inhabitants of the nations with whom they had treaties and commercial intercourse, even among the most learned men and the most distinguished, that it could have contained little or nothing worthy of preservation. Had there been either of wisdom or of art embodied in their works they had, we should have had translations, known to us at least by the same as those of Mago's book on agriculture, of a few circumnavigations and mari-

time explorations. Of their architecture, their arts, we have neither a relic nor a record. Of their religion we know from Scripture and from more recent history, that it was a cruel and bloody superstition. They worshipped on high places, and they had sacred groves, as well as idols, which were held in particular abomination by the true followers and subjects of the Jewish theocracy, and which were yet constantly owned as gods, frequented and worshipped by the backsliders, both of the princes and of the people of Israel; a singular proof, if proof were needed, of the close connection, both in race and language, as well as in social habits and modes of thought, between the children of Israel and the Phœnicians, whether of Syria or of Africa, who called themselves *Kanaanim*, which we render Canaanites, so late as to the time of St. Augustine, and so far from the place where the name was first obtained as Hippo Regius, to the westward of the site of Carthage. Their principal god was Baal, Belshamen, or the ancient one, Moloch, as he was called by the Jewish rabbinical writers, who was considered by the Greeks as identical with *Kpovos* or Saturn, and who, in process of time, became in some features assimilated to Apollo. He was evidently the fire-god or sun-god, and to him were offered the human sacrifices, of children more especially, who were placed on the extended palms of the metallic statue, whence they rolled into a fiery furnace. To the sun-god was associated a female deity, expressive, it is believed, of the productive power of nature under the generative power of the sun, worshipped as the queen of heaven, Ashtoreth or Astarte, who is identical with the Venus Mylitta of Babylon, the Astartis of Armenia, and the Venus Urania of Cyprus, of whose rites the sexual lusts were as distinct a feature, as was the fiery death the head and front of those of the male deity. In Africa the worship of Ammon seems to have been associated with that of Baal, and of the sacred elephant; while that of Melkarth, the Punic Hercules, was celebrated by the lighting of yearly funeral pyres, and the release of an eagle, typical of the sun, and of the legendary phoenix renewing himself from his own ashes. The offering of human sacrifices extended so far to the westward as to Cadiz, where there existed a temple and statue of Baal-Saturn, under the Roman dominion; and continued so late as to the times of the Roman emperors, more than one of whom published edicts in vain, prohibitory of these barbarous immolations."—The first period of the history of Carthage extends to the beginning of the war with Syracuse, from the commencement of the city, whenever that occurred, nominally B. C. 878 to 480; during which time she had conquered her African empire, Sardinia and the adjacent isles; waged wars with Massilia and the Etrurians, on commercial grounds; prosecuted her voyages of discovery, traffic, and colonization along the coasts of Spain, far out into the Atlantic; established trading intercourse with the Scilly Isles and

parts of the British coast; and, as some believe, pushed her adventures so far as to the inhospitable shores of the Baltic, where she is reported to have collected amber at the mouth of the river Rhodan. Of this period we know nothing from records, either of her own or her contemporaries, and can judge only by her condition, the state of her trade and resources, and the extent of her dominions at the time when we first have any authentic information of her greatness, which is to be found in the commercial treaty with Rome alluded to above, passed in the year 509 B. C. Thirty years after this date commences the 2d, and by far the most splendid period of Carthaginian history. It opens with their efforts to conquer and attach to their empire the great, rich, and fertile island of Sicily, and closes 265 B. C., with the outbreaking of the first Punic war. The Syracusan war was waged long and with various success. In the simultaneous attempt of the Persians on the Hellenic, and the Carthaginians on the Sicilian Greeks, the latter were defeated at Himera, by Gelon, tyrant or king of Syracuse, with nearly as much loss as was their ally, Xerxes, at Salamis. As a condition of peace they were compelled to renounce human sacrifices in their Sicilian trading posts and settlements. In the war with Hiero, Gelon's successor, they conquered and held in occupation the cities of Himera, Selinus, and Agrigentum. With Dionysius they were for a short time at peace, and then employed themselves in consolidating their former conquests on the island, which were now very rich and strong, consisting of well-fortified seaports, fortresses, dockyards, naval stations, and garrisons, backed by considerable territorial domains of great productiveness and wealth. After the reestablishment of republicanism in the Greek cities by Timoleon, the Carthaginians were almost invariably unfortunate; but, during the tyranny of that singularly able adventurer, Agathocles, the war was pressed with so much vigor by them, on his attempting, after the policy of Dionysius, to drive them out of the island, that he was defeated, reduced to all but extremity, and besieged in his capital of Syracuse, when, by a masterly stroke, which doubtless suggested the similar enterprise of Scipio, he broke out of the beleaguered city with a portion of his army, and carried the war into Africa. There he overran the open country, took 200 towns—for Carthage had no fortified places to delay an invading army, and no native peasantry or agricultural citizens of whom she could make a levy *en masse*, with which to protect her soil—and, although he was twice personally called back to Sicily to quell mutinies and restore order in his home dominions, actually maintained himself 4 entire years on African soil, at the gates of Carthage, which he reduced to at least equal distress with that of Rome during the similar, but far more brilliant invasion of Hannibal. At length his fortune turned, his armies in Africa were obliged to surrender, and in the year 306 B. C. he concluded a peace which re-

stored order to Sicily, and established both parties in possession of the territories each held before the breaking out of the war. After his death, the Carthaginians increased their possessions and power in Sicily, and established themselves as actual masters and sovereigns of the Balearic isles, Corsica, Sardinia, and the Liparian islands, thus girding the whole Roman seaboard with a belt of insular fortresses. Thus far, however, all was peace and amity between the two great republics of antiquity. In fact, immediately after the battle of Asculum, when Rome was in considerable straits, owing to the prolonged occupation of Italy by Pyrrhus, king of Epirus, and to his continual successes, a Carthaginian fleet of 120 ships of war appeared off Ostia, and offered assistance against the Greek, who was in some sort regarded as a common enemy of both republics; and although the offer was declined, the commander acted in good faith toward the Romans, assisting them in their siege of Rhegium, and in other enterprises, the end of which was to prevent the Sicilian Greeks from lending their aid to the king of Epirus and his allies, the Greek states of Italy. The retreat of Pyrrhus, in the year 275 B. C., left the Romans almost undisputed masters of Italy, and the course of the next 10 years rendered them absolutely so. In the mean time, Carthage had become yet more influential in Sicily, and was bent on converting influence and ascendancy into empire and possession. The little strait of Messina now alone divided the possessions and separated the armed forces of the two powerful, ambitious, encroaching, and already, it is probable, half-jealous states. Each, it is clear, already aimed at supremacy in Europe. Greece was already falling, if she had not fallen, into decrepitude, and could no longer pretend, through want of concert and united action, to any considerable power beyond her own limits. The Greek Egyptian empire of the Ptolemies, which was entirely isolated from the mother country, and which had long known Carthage by means of her commercial energy, on the tidings of the victory of Rome over the Greek arms of Pyrrhus, thought it advisable to seek intercourse and alliance with the strong young republic of the west. In a word, Rome had made herself known and respected beyond her own shores, and the contest between her and Carthage was inevitable. It arose, as might have been expected, with the invocation of Roman aid by the Mamertines, belonging to an Italian city of Sicily, against the Carthaginians; which being gladly rendered, as by a people seeking pretext of war, gave birth to the first Punic war, which broke out 265 B. C., and may be regarded as the commencement of the third period of Carthaginian history. This war lasted for more than 23 years. It was waged (with the exception of one invasion, by Marcus Regulus, of Carthaginian territory, which, in the outset successful, terminated in disaster, defeat, and the capture of the Roman general) either on the island of Sicily or on the waters

ranean. On the latter, at first, suffered bloody defeats and reverses, in a word, sufficient to discourage the hardest and most persevering. Still they persevered, and when the war broke out, they had not a single ship of war, a single mariner, or an officer who had seen sea service, in the end obtained the mastery of the Mediterranean, the last fleet which the Carthaginians met, in a terrible conflict off the island of Sicily, at the W. angle of Sicily, and granted terms which their enemy sued for, on condition that the Carthaginians should evacuate Sicily, and the isles thence to the Italian coast, and deliver Roman prisoners without exchange, and pay the expenses of the war, at the rate of 3,200 Euboic talents, or \$3,337,888, in the space of the 10 years next ensuing. The treaty was decisive, but the efforts it had cost were prodigious. The census of the Carthaginians, in those 22 years, had sunk from 797,000 to 251,222 men capable of bearing arms, while the decrease among the Latin allies must have been at least equally great, and such was the exhaustion of silver and depreciation of brass, that the Roman pound, before the war, was reduced to 2 ounces at the end of it. Twenty-two years of peace passed before the commencement of the war; and during the interval, although Carthage lost Sardinia, of which the Romans, anxious to their credit, made themselves masters, taking advantage of a mutiny of the Carthagean mercenaries, Carthage had more than made up all her losses, by the conquest and possession of the vast and rich Spanish peninsula, its virgin gold mines, and its bold and brave population, furnishing the best infantry in the world, and an inexhaustible supply of recruits. Since 2 countries are equally desirous of war, all pretext suffices. But it was especially the policy of the Barcas, whose genius conquered the whole of Spain in the last century, and, in the next, nearly conquered Rome, to bring on a war with that country; and Hannibal, the son of Hamilcar, obedient to the idea to which he had been inured by his father in his childhood, and with it foremost in his mind to manœuvre, forced what he desired, by laying siege to Saguntum, an allied city of the Romans on the seacoast, now Murviedro, and against the Ebro contrary to protest, if not to the passage of Hannibal across the Alps, the battles of the Ticinus, the Trebia, Thrasymene, and Cannæ, the defeat on the Metaurus, the death of Hasdrubal, the 16 Italian victories, the simultaneous victories of the Romans in Spain and Sicily, the transfer of the Carthaginians to Africa by the elder Scipio Africanus, the defeat at Zama, and the total submission, disarmament, and disarming of Carthage, are the incidents of the 2d Punic war. Alto-

gether they contain the history of the most marvellous contest that ever was maintained between the genius of a single individual, almost unassisted by his government, and the resources, perseverance, and magnanimous constancy of a great nation. It is hard to say which is most to be admired, the unrivalled strategic and political genius, the firm tenacity, wondrous skill, and deep wisdom of Hannibal, or the indomitable persistency, unhesitating devotion, and iron will of Rome. The 2d Punic war was concluded 201 B. C., by the virtual subjection of Carthage. An interval of 53 years followed, during which Rome constantly and steadily pursued her course of aggrandizement, by the wars against Philip, Antiochus, and Persius, by which she subjugated Greece, and gained vast oriental lustre and ascendancy, while, incited by the unrelenting hatred of Cato the censor, she encouraged her friends and allies to commit aggressions on Carthage; until at length, provoked beyond the limits of endurance, that city, in despair, took up arms to repel unendurable insult and provocation, forgetful or regardless of the clause in the late treaty which forbade them to take up arms on any pretext, or against any nation whatsoever, without consent of the Romans. After this, treacherously and dishonestly, the Romans, as the price of peace, extorted from them all their remaining ships of war, all their arms, military engines and supplies, compelled them to give 300 hostages, and then commanded them, as the only alternative by which to escape destruction, to abandon their city and seashore position, and to remove 10 m. inland. War was instantly declared, and for 8 years the unarmed, almost defenceless citizens of Rome's great rival maintained a warfare of despair. At the end of that space, a second Scipio, the son of Paulus Æmilius, the conqueror of Persius, adopted by the son of the conqueror of Hannibal, took the city by storm, and destroyed it, razing it to the ground, passing the ploughshare over its site, and sowing salt in the furrows, the emblem of barrenness and annihilation. The city was 28 m. in circumference; the inhabitants fought from street to street, while the houses burned over their heads, during 17 days, until 55,000 persons, the whole of the survivors of a nation, were shut up in the ancient citadel called Byrsa, where they surrendered at discretion, and were all sold into slavery. Hasdrubal only, the commander, with his wife, children, and 900 Roman deserters, took refuge in the temple of Æsculapius, with the determination to defend themselves to the last, and die under the ruins of the last Punic edifice. The heart of the leader failed him, and while his wife and all his followers met the death from which he meanly shrank, he surrendered himself to be led in triumph, and to die by the hands of the Roman carnifex in the Tullianum. Long afterward, Cæsar planted a small colony on the ruins of Carthage; and Augustus, his successor, built a city, of the same name, at a small distance, in order to

avoid the imprecations which it was the habit of the Romans to invoke on the rebuilders of any city destroyed by their arms. This place attained some eminence; it was conquered by Genseric, from the Romans, A. D. 439, and continued to be the seat of the African empire of the Vandals for about a century, when it was conquered by Belisarius in 534. It was finally destroyed by the Saracens in the caliphate of Abd el Melek, in the latter part of the 7th century, and no vestiges of it remain except the ruins of an aqueduct, and a fragment of the western walls, at about 12 m. from Tunis.

CARTHAGENA, or CARTAGENA, a province of New Granada, South America, bounded N. W. and W. by the Caribbean sea and the gulf of Darien, N. E. by the province of Savanilla, E. by the rivers San Jorge and Magdalena, S. by the province of Antioquia; pop. in 1851, 103,783. In the N. the surface is low and partly covered with salt-water pools. The S. part is mountainous and thickly wooded, but has many fertile valleys, in which are produced rice, Indian corn, cotton, and sugar. Various rich fruits grow spontaneously, and the forests produce valuable timber. The trade, once very extensive, has declined considerably, and the principal exports now consist of precious metals. There are no large rivers except those on the E. border.—CARTHAGENA, or CARTAGENA, the capital and chief town of the above-described province, one of the principal ports on the Caribbean sea, and the chief naval arsenal of New Granada, is built on a small sandy peninsula, near the entrance to the gulf of Darien, connected with the mainland by narrow necks of land and wooden bridges; pop. in 1851, 83,700. The harbor is well protected, commodious, and the only one on the N. coast of New Granada fitted for repairing vessels. There were formerly 2 entrances, one close to the town, the other several miles further S.; but the better to defend the approach, the former has been blocked up by sinking old vessels in it. The defences of the town are extensive, though singularly incomplete. Both Carthagena itself and the island suburb of Xiximani are surrounded by freestone fortifications, which are commanded by a strong work on an eminence on the mainland, but the latter is overlooked by a range of heights towering 400 feet above it, which, though they have several times caused the fall of the city without a shot, have never been fortified. On their summit is an Augustinian monastery. Carthagena is well built, with stone houses, generally 2 stories high, having balconies and lattices of wood. Many of the churches and convents are very handsome. There are 2 hospitals, a town hall, a college with about 200 pupils, a strong citadel, a theatre, and a circus. The climate is hot and unhealthy; leprosy and yellow fever are the most common diseases, but greater attention to cleanliness has lately diminished the ratio of mortality. The chief manufactures are ropes and sail-cloth. The exports, comprising most of the produce of the

valleys of the Cauca and Magdalena, with the latter of which rivers Carthagena is connected by canal, viz., sugar, cotton, coffee, tobacco, hides, specie, bullion, &c., amounted to \$500,000 in 1852; and all the imports, which consist of iron, steel, copper, hardware, chinaware, machinery, tea, pimento, brandy, rice, sugar, cocoa, coffee, wax, dye-wood, &c., to \$2,000,000. Carthagena was founded by Pedro de Heredia in 1533, pillaged several times by pirates, taken by Sir Francis Drake in 1586, by the French in 1697, and besieged unsuccessfully by the English in 1741. It was the first town that declared for independence, and during the war that followed, often changed hands.

CARTHAGENA, or CARTAGENA (anc. *Carthago Nova*, New Carthage), a seaport town of Spain, capital of a district of the same name in the province of Murcia; lat. 37° 36' N., long. 0° 56' W.; pop. including suburbs in 1852, 51,593. It is built at the head of a deep, well-sheltered harbor, flanked by steep hills, defended by works at its mouth, and forming one of the best ports on the Mediterranean. The town itself is walled and neatly built; the streets are wide, regular, and relieved by several public squares, one of which, with a fine fountain in its centre, is enclosed by elegant buildings. The old cathedral, now a simple church, is an edifice of little beauty. There are several other churches, convents, hospitals, an observatory, an artillery park, a splendid arsenal, barracks, dock yards, foundries, ropewalks, and a glass factory; but little activity is observable in the streets, and every thing bears the mark of rapid decay. Notwithstanding its commodious port, the town has little or no commerce. The inhabitants are employed chiefly in lead and silver mining, fishing, and exporting barrilla, grain, and esparto (Spanish grasshemp). The mineral wealth of the neighborhood was known in very early times, and the yield of silver enabled Hannibal to carry on his war against the Romans. The new mine of La Carmen was opened in 1839, and the veins have since been successfully worked by a joint stock company. Carthagena was founded by Hasdrubal, the Carthaginian general, 242 B. C.; was taken by Scipio, 210 B. C., at which period, Livy states, it was one of the richest cities in the world; was almost destroyed by the Goths, rose to great importance in the time of Philip II., and in 1786 had 60,000 inhabitants. It was made the great naval arsenal of Spain, but is now visited only by a few fishing and other craft, and by coasting vessels, which make it one of their intermediate stations. Its decline is owing in some measure to its unhealthy climate.

CARTHAMUS, the dyer's saffron or safflower. The plant known as the *carthamus tinctorius*, from which this flower is obtained, is a native of India and Egypt. It is imported into the United States principally from the Mediterranean. It is grown in considerable quantities in this country, under the name of American saffron. The flowers, the only part

contain 2 coloring matters, one red, the yellow; the red, insoluble in water, and yellow, easily removed by treating it with liquid. The red alone is employed in dye-

It is called carthameine, and is supposed to owe its color to the oxidation of a peculiar principle called carthamine, existing in the petals. The yellow coloring matter is removed by soaking the flowers placed in a bag in water, until nothing more can be dissolved. The carthamus, which before was reddish yellow, loses half its weight, and becomes a clear red. The red coloring matter is then extracted from the flowers, in treating them with a dilute solution of carbonate of soda, and adding an acid to precipitate the carthameine. The quantity obtained is only 1 per cent. of the weight of the flowers.

Carthamine is a most beautiful color, but unfortunately is not permanent, so cannot be employed in the dyeing of wool and cotton; but for silks, where a brilliant rather than enduring color is desired, carthamus is much used, for producing the finest shades of red, such as rose and flesh color. Carthamus is also used for preparing a very beautiful color (*rouge d'assiette*), which is employed in coloring artificial flowers. A vegetable rouge is also manufactured from it, by mixing with the *rouge* finely pulverized white talc. The mixture is then rubbed in a mortar with a little oil, and moistened with sulphuric ether. A superior rouge is sometimes prepared by substituting carmine for carthamine.

CARTHEUSER, JOHANN FRIEDRICH, a German physician, born Sept. 29, 1704, died at Frankfurt on the Oder, June 22, 1777. He studied medicine first at Jena and afterward at Halle, where he was admitted to the degree of doctor in 1731. He was appointed in 1740 professor of chemistry, pharmacy, and materia medica, at the university of Frankfort on the Oder, and shortly afterward to the chair of anatomy and botany. Still later he was named professor of pathology and therapeutics. He was also appointed rector of the university, and continued to hold his appointments as long as he lived. His chief merit consists in having introduced the method of submitting the various substances of materia medica to a strict course of chemical analysis. He analyzed a great number of plants and other substances, and gave an exact account of the elements which enter into their composition. He published a considerable number of scientific papers and dissertations, on many and various subjects, during a long succession of years.

CARTHUSIANS, a religious order, founded by St. Bruno, A. D. 1084. The first monastery of the order was built in a wild and solitary district 6 miles from Grenoble, in the department of Isère, known as La Chartreuse, whence the order took its name. The observances of the Carthusian monks were austere and penitential in an extraordinary degree, even among contemplative orders. They devoted a portion of their time to manual labor, consisting chiefly

in the transcribing of ancient MSS. Their labors as agriculturists gained great renown for their name, for they reclaimed marshy and unhealthy neighborhoods, and caused the rocky and barren fastnesses of La Chartreuse and other desert regions to bloom with the fruits of patient and intelligent toil. They had rich and celebrated abbeys in England, France, and Germany. The Certosa of Pavia, and that of St. Elmo at Naples, are still visited by travellers, and a Carthusian community occupies as a convent the baths of Diocletian in Rome.

CARTIER, JACQUES, a French navigator, born at St. Malo, Dec. 31, 1494, died probably at an advanced age. Under the auspices of Francis I., he was intrusted with the command of an expedition to explore the western hemisphere. He sailed from St. Malo, April 20, 1534, with 2 ships of 60 tons each, and a crew of 120 men, and in 20 days reached the E. coast of Newfoundland; thence steering N., he entered the straits of Belle Isle, and took possession of the coast of Labrador by planting there a cross near Rock bay. He next turned S., and followed the W. coast of Newfoundland to the straits between Capes Ray and Breton, when he was borne W. by unfavorable weather toward Magdalen islands. After visiting them, he continued W., landed at the mouth of the Miramichi, whence he went with some of his men to explore the bay of Chaleurs, and a few days later sailed with his 2 ships, to land again a little further N. in the bay of Gaspé, which he mistook for the outlet of a large river. He there had friendly intercourse with the savages, and inspired them with such confidence, that one of their chiefs permitted 2 of his sons to go with him to France, on condition that he would bring them back the following year. There he planted another wooden cross, to which was attached a shield bearing the arms of his king, and the words, *Vive le roi de France!* He next proceeded N. E., doubled the E. point of Anticosti, and entering the channel which separates the island from the continent, sailed up that branch of the St. Lawrence, not being aware, however, of the existence of the river. As winter was approaching, he thought it prudent to return, again passed the straits of Belle Isle, and arrived at St. Malo Sept. 5, 1534, after an absence of less than 6 months. This successful voyage encouraged the king to new efforts: 3 well-furnished ships were fitted out for another expedition, which was joined by some of the young nobility of France, and Cartier was appointed commander, being designated in the commission as "captain and pilot of the king." About the middle of May, 1535, Cartier assembled his companions and men on Whit-Sunday, and repaired to the cathedral, where a solemn mass was celebrated, after which the whole company received absolution and the bishop's blessing. The squadron—consisting of *La Grande Hermine*, a vessel of 120 tons, *La Petite Hermine*, of 60, and *L'Emérillon*, a smaller craft—sailed May 19. Storms soon separated the 3

vessels, which, after a rough voyage, arrived successively at their place of rendezvous, the inlet of Blanc Sablon, in the straits of Belle Isle. On July 31 they sailed W., entered the channel between the mainland and Anticosti, which he called Ile de l'Assomption; sailed up the river St. Lawrence; saw, Sept. 1, the mouth of the Saguenay; and on Sept. 14 came to the entrance of a river, some 30 m. below Quebec, to which he gave the name of Sainte Croix. The next day he was visited by Donnacona, an Algonquin chief, with whom he was enabled to converse, the 2 Indians whom he had the previous year taken from Gaspé to France acting as interpreters. Leaving his 2 larger ships safely moored, he, with the *Emérillon*, sailed up the stream as far as Lake St. Peter; there, his further progress being interrupted by a bar in the river, he took to his boat with 8 volunteers, and on Oct. 2 arrived at an Indian settlement called Hochelaga, which he called Royal Mount, whence the present name Montreal. On the 5th he left Hochelaga and rejoined his ships at the mouth of the Sainte Croix, where he passed the winter. With his men, he suffered from the severity of the climate, but above all from the scurvy, which made frightful ravages among them; no less than 25 soon died; and out of 110 still surviving, in Feb. 1536, only a few were free from the disease. Owing to the reduction of their number, Cartier decided to abandon the *Petite Hermine*, which vessel was discovered in 1848 embedded in the mud. After having taken solemn possession of the land in the name of Francis I., by erecting a cross bearing the arms of France, with the inscription, *Franciscus primus, Dei gratia Francorum rex, regnat*, he sailed May 6, carrying with him Donnacona and 9 other chiefs, whom he had somewhat treacherously kidnapped; went through the channel S. of Anticosti, and the straits S. of Newfoundland, and once more reached St. Malo, July 16, 1536. The hardships which had been incurred during the expedition were not encouraging to colonization; but at last the entreaties of Francis de La Roque, lord of Roberval in Picardy, prevailed; he was appointed viceroy and lieutenant-general of the new territories, while Cartier preserved the title of captain-general and chief pilot of the king's ships. Five vessels were now fitted out; Cartier sailed with 2 of them, May 23, 1541; he was soon joined by the 3 others, and they arrived at Sainte Croix Aug. 23. On exploring the neighboring country, Cartier found a better harbor at the mouth of the Red river, to which he took 3 of his ships, while the 2 others returned to France after landing their cargoes. Cartier then visited Hochelaga for the 2d time, with the particular purpose of ascertaining the obstructions to further navigation. The winter passed in gloom. Toward the end of May, 1542, nothing having been heard from Roberval, provisions becoming scarce, and the savages evincing unfavorable feelings, Cartier sailed for France. On his way he met Roberval, who

ordered him to continue his voyage, and arrived with him at the village of L'Assomption; the time he lived there is unknown. A brief, but interesting account of his expedition appeared anonymously in 1545. The journals of the two 1st journeys of Cartier are inserted in the 3d vol. of Ramusio's Italian collection (Venice, 1555), also in Marc Lescarbot's *Histoire de la Nouvelle France*; while a description of his 3d journey is to be found in the 3d vol. of Hakluyt's "Principal Navigation," &c. (1600).

**CARTILAGE**, a firm, elastic substance, of an apparently homogeneous structure, bearing some analogy to bone, and entering largely into the composition of the animal skeleton; in its intimate structure it approaches very closely the cellular tissues of vegetables. It constitutes the rudimentary skeleton of the higher molluscs, and of the selachian fishes, hence called cartilaginous fishes, in man and the higher animals, it forms the internal skeleton at the early periods of life, and is in all employed as a nidus for the development of bone. The organic basis of cartilage is a variety called chondrine; this, like gelatin, in solution solidifies on cooling, is precipitated by alcohol, creosote, tannic acid, corrosive sublimate, and is not precipitated by ferrocyanide of potassium; but, unlike gelatin, it is precipitable with acetic and other acids, with alum, permanganate of potash, and acetate of lead. True cartilage has a white or bluish white appearance: the structure is of a yellowish color, and ex-temperamentum. Temporary cartilages take the place of bone in early life, and eventually come ossified; for a considerable time after birth the ends of the long bones are chiefly of cartilage, and the extremities are united to the shafts by bone until the 1st year. Permanent cartilages are divided into two kinds, the articular and the membranous; the skeleton of the selachians is entirely of cartilage. Articular cartilages cover the bones entering into the formation of a joint, either a thin layer between the bones, as those of the cranial sutures, the sacrum, or incrusting the articulation, as in the ball-and-socket and braniform cartilages have no articulation, but serve to keep open the cavity, and the mere force of their elasticity, as in the cartilages of the external ear, nose, eyelids, Eustachian tube, and vocal cords. The distinguishing characters of cartilage are elasticity, flexibility, and cohesion; it is not easily broken, and will assume and retain its proper shape when subjected to pressure. These varieties of cartilage, as they are called, are covered with a membrane analogous to the peritoneum, which serves as support to the vessels and nerves in the simplest form of

large, ovoid, more or less flattened by their contact; the diminutive nucleua, attached to the cell wall, contains a minute nucleolus; these cells are scattered irregularly in an intercellular substance, or hyaline matrix, which contains numerous granules, many of which, according to Hassall, must be regarded as the cytoblasts from which new cells are developed; the amount of this substance is greatest in the fully developed cartilage. In the condensed margin of true cartilage, the cells are compressed, with their long diameters parallel to the surface they cover; when ossification begins in temporary cartilage, the cells become disposed in rows, as described in the article on Bone. In the articular cartilages the cells are arranged in small groups in an abundant hyaline matrix; they measure from  $\frac{1}{350}$  to  $\frac{1}{250}$  of an inch; in their deep portions these cartilages gradually blend with the bone, which dips unevenly into the surface of the cartilage. In the cartilages of the ear the cells are larger than in any other, measuring from  $\frac{1}{35}$  to  $\frac{1}{25}$  of an inch in diameter; they often have a linear arrangement, and are embedded in a very abundant intercellular substance, which sometimes presents a distinctly striated structure, though not resembling white fibrous tissue. In the membraniform cartilages the cells are very numerous in proportion to the intercellular substance, which is so fibrous in character in the external ear as to appear very near to fibro-cartilage; the ear of the whale is a good specimen of this form, and in its central portion a series of six cells arranged in layers one above the other, resembling, except in size, the transverse section of the pith of a plant. Cartilage is sometimes found as an accidental and diseased production. *Enchondroma* is a tumor attached to bone, containing cells like those of cartilage, and others of a peculiar form resembling the lacunae of bone. In the articulations, especially in the knee-joint, loose rounded bodies are often found, of a cartilaginous consistence, frequently as large as the knee-pan; these interfere with the motions of joints, and are sometimes removed by excision. The cartilage cells of reptiles are larger than those of fishes, being largest in the snake; in birds cartilage is very early condensed into bone, so that they have very little left except in the joints; the largest cells are found in the mammals, according to Mr. Quekett, in the elephant. Cartilage belongs to the class of cellular substances, as considerable quantities are found unpenetrated by a single blood vessel; articular cartilage is non-vascular, except in some diseased conditions when the presence of a few vessels seems to have been detected; temporary cartilage also, when of considerable thickness, has no vessels, but when of considerable thickness, the delicate extensions of the investing perichondrium penetrate it in a reticulated manner; the membraniform resemble the temporary cartilages in respect to vascularity. The nutriment of articular cartilage is derived from the vessels of the joint, and from

the synovial membrane, though none of these enter its substance, the nutrient material passing from cell to cell by imbibition; in cartilages of ossification vessels regularly appear, accompanying the process of bone-formation. According to Hassall, cartilage cells are multiplied in 2 ways: 1, by the division of a single cell into 2 or more parts, each becoming a distinct cell; 2, by the development of cytoblasts in the intercellular substance, or in the parent cells, constituting a true reproduction, constantly going on. In this multiplication by division, and by development of secondary in parent cells, cartilages resemble the *algæ*, and herein they stand alone in the animal economy. Cartilage cannot be regenerated; fractured surfaces are united only by a condensed cellular tissue. As cartilages do not contain nerves and vessels, they are not subject to inflammation and its consequences; the so-called ulceration of cartilage is effected, not through the cartilage itself, but by the vessels entering it from bone and synovial membrane, and occasioning a partial erosion.—There is a form of tissue which may be described here, as it differs from cartilage chiefly in having its intercellular substance replaced by white fibrous tissue; it is therefore called fibro-cartilage. It occurs principally in the joints, where its strength and elasticity are most needed. Its color is white, slightly tinged with yellow, with the shining fibres of the white fibrous tissue quite conspicuous; its consistence varies from pulpy to very dense. The fibres are arranged in an intricate and interlaced manner, strongest in that direction in which the greatest toughness is required. To the strength of fibrous tissue is added the elasticity of cartilage; its vessels are few and derived from adjacent textures, and no nerves have been detected in it; its sensibility is low, and it has no vital contractility. The disks between the vertebræ are fibro-cartilage; their elasticity diminishes the shocks to which the spinal column is necessarily subjected; in the whale these disks are very large, detached from the vertebral bodies, and more or less ossified. In the diarthrodial joints, as in the sterno-clavicular, temporo-maxillary, and knee joints, there are fibrous laminae, free on both surfaces, called *menisci*; in these the circumference is fibro-cartilage, and the centre more cartilaginous. On the edges of the shoulder and hip joints is a rim of fibro-cartilage, giving depth to the articular cavities. In the grooves in bone for the lodgment of tendons we find another instance of the occurrence of fibro-cartilage. Fibro-cartilage is not so prone to ossification as the simple fibrous structures; it is repaired by a new substance of similar texture; in cases of false joint from the non-union of fractured bone, the broken ends are sometimes connected by fibro-cartilage. The pubic bones at the symphysis are united by this tissue. Fibro-cartilage is less soluble in water than true cartilage, and yields therefore less chondrine.—The uses of cartilage and fibro-cartilage are entirely of a

mechanical nature; their structure is admirably adapted for the protection of organs by their solidity, flexibility, and elasticity. For a complete account of the intimate structure of articular cartilage, the reader is referred to a paper by Dr. Joseph Leidy, in vol. xvii. of the "American Journal of Medical Sciences," new series, and to the works of Müller, Todd and Bowman, Hassall, and Quekett.

**CARTOON** (It. *cartone*, from Lat. *charta*, paper), a picture drawn upon thick paper, with white and brown, or black, and intended to be a model for a fresco, or for tapestry. When the cartoon is used, its back is covered with black lead, and being placed against the wall or canvas, the outlines are traced with a pointed instrument. Sometimes the outlines are pricked through, and a coloring matter rubbed over it. Or, by drawing intersecting lines on both the cartoon and the canvas, forming squares equal in size, by their guidance, a copy may be made correct in position and proportion. Cartoons exhibit the greatest efforts of some of the masters in painting. There are 7 by Raphael, now in Hampton Court, England, which probably are not excelled in completeness and beauty by any paintings in existence. Leo X. employed Raphael to make designs for tapestry, and 2 sets were finished in tapestry at Arras in Flanders. One set, supposed to have been originally 25 in number, was sent to Rome, and was carried away twice: first in 1526, afterward restored entire; the second time in 1798, and all but one restored in 1814, which was supposed to have been destroyed for the gold used in its making. The cartoons themselves were kept as lumber in the factory in Flanders, until, on the recommendation of Rubens, Charles I. of England purchased the 7 which had escaped destruction. They were much injured by being pricked and cut in tracing them for the canvas. When the royal collection was sold, these cartoons were preserved to England by Cromwell's special command. During the reign of Charles II. they were consigned to neglect, but William III. had them placed in Hampton Court. They represent the following subjects: "Paul preaching at Athens," the "Death of Ananias," "Elymas the Sorcerer struck with Blindness," "Christ Delivering the Keys to St. Peter," the "Sacrifice at Lystra," the "Apostles healing the sick in the Temple," and the "Miraculous Draught of Fishes." Two cartoons of Raphael, said to belong to a set which was sent to Flanders, are in the possession of the king of Sardinia. The Palazzo Gualtieri at Orvieto contains a valuable collection of cartoons by Domenichino, Annibale Carracci, Franceschini, Albani, &c. In the Ambrosian library at Milan is the original cartoon of Raphael's "School of Athens," the fresco of which is in the Vatican.

**CARTOUCH**, (Fr. *cartouche*), in old military works, used sometimes as synonymous with case or grape shot. It is also now and then used to

designate  
dier.—In  
modillon  
ment on w  
scription.

**CARTOUCHE**, Louis D 1077 a real  
French robber, born in 1  
Nov. 28, 1721. He o  
peradoes, whose robbe... and murder  
terror among the Parisians. For  
deed, notwithstanding a high p  
put on his head, he baffled the  
was but accidentally arrested. His t

**CARTRIDGE**, a paper, parcel  
nel case or bag containing the e  
gunpowder used for the ch  
and to which, in some inst  
is attached. Blank cartridge, for  
does not contain a bullet; ball  
In all small-arm cartridge the  
a wad, and rammed down. The  
the French Minié and British E  
steeped in grease at one end, so as to  
ramming down. That of the P  
gun contains also the fulminating  
exploded by the action of the needle.  
for cannon are generally made of  
other light woollen cloth. In  
those for field service at least  
tile attached to the cartridge by  
wooden bottom whenever practicable;  
French have partially introduced this,  
even into their naval service. T  
have cartridge and shot sep  
well as in naval and si  
nious method of making paper cartridge  
seams has been lately introduced  
arsenal, Woolwich, England.  
drical hollow moulds, just large en  
cartridge to slip over, are perforated  
multitude of small holes, and being  
into the soft pulp of which ca  
made, and then connected with a  
receiver of an air-pump, are  
ed with a thin layer of the pulp.  
dried, is a complete paper tube.  
are arranged many together: and  
provided with a worsted cord  
of a glove, upon which the  
this being taken off with it serves  
with which the best cartridges are  
A kind of cartridge is in use  
made of a network of wire  
shot only. It is included in  
paper. The charge of shot is  
dust to give compactness.  
fired, the shot are carried a  
greater distance without  
charged in any other way.

**CARTWRIGHT**, Edmund, an English clergy-

inventor of the power loom, born at Marnham, Nottinghamshire, April 24, 1748, died 1828. Being intended for the church he received his education at Oxford, and soon entered upon the duties of his profession. His life was passed in lettered ease, and was chiefly devoted to poetical composition. In the summer of 1784 happening to be in lock, he had a conversation with some men from Manchester on the subject of mechanical weaving. He had never till now, in his 40th year, taken any interest in mechanics, but by April of the succeeding year, his first power loom in running order. Opposition was opposed equally by spinners and weaver workmen. The one class saw in it a machine that would deprive them of bread; the other feared it was a device that would diminish their profits. A mob set fire to the first factory and destroyed it with 500 spindles. Improvements were added to the original machine, and it made its way. For many years, however, Cartwright derived no pecuniary benefit from his invention. He patented several other machines, of which the principal was one for wool-carding. Numerous societies awarded him medals, but he received no substantial benefit from any of his inventions until 1807, when, in recognition of the principal cotton spinners, the House of Commons voted him £10,000. This sum placed him in easy circumstances. He devoted his time to experiments in the adaptation of steam to boats and carriages, but died without achieving any important result.

CARTWRIGHT, JOHN, elder brother of the preceding, an English political reformer, born at Marnham, Nottinghamshire, 1740, died Sept. 23, 1824. At the age of 18 he entered the navy, but at 35 was still a lieutenant.

Meantime the struggle between Britain and her colonies enlisted his sympathies with the Americans. In 1774 he published his sentiments in an essay entitled "American Independence, the Glory and Interest of Great Britain." At the same time, he requested to be placed on the retired list, rather than to fight against the colonists. Lord Howe vainly tried to shake his resolution in this respect.

Having retired to Nottinghamshire, he possessed some property, the lord lieutenant gave him a commission as major in the militia. His appointment gave great satisfaction to the government, who signified their approbation so pointedly to the lord lieutenant that he refused Cartwright the usual promotion to the lieutenant-colonelcy, and in 5 successive vacancies occurred in the militia. Finally he retired from the regiment in 1792. About this time he removed to Nottinghamshire. His name now becomes prominent in the history of parliamentary reform. He attended for annual parliaments and universal suffrage. These he supported with voice and pen, in coöperation with Dr. Jebb, Grantham, Harpe, Horne Tooke, Hardy, Thelwall, Hunt, and other liberals of the day.

Mainly through his instrumentality the citizens of Birmingham were induced to elect a delegate claiming a seat in parliament under the name of their legislative attorney, although that city, the 8d in the kingdom, had no representation in that body. For his share in this proceeding, Cartwright was tried for sedition, and fined £100. Again, when procuring signatures in Huddersfield to a mammoth petition, he was arrested on a charge of exciting to riot, but released. The English liberals placed much reliance in the integrity of his purposes. Sir William Jones declared that his declaration of the people's rights should be written in letters of gold. Fox, in his place in parliament, declared that few men united so complete a knowledge of the people's constitutional rights, with such high intelligence, and such conscientious views. Byron, in the house of lords, declared that his long life had been spent in one unceasing struggle for the liberty of the subject. His views on the American revolution were summed up in this sentence: "The liberty of man is not derived from charters but from God, and is original in every man." He was one of the earliest who maintained the doctrine that the slave trade was piracy. A bronze statue is erected in his honor in Burton-crescent, London. His life was published by his niece (2 vols. 8vo. Lond., 1826).

CARTWRIGHT, THOMAS, a Puritan divine, born in Hertfordshire about 1585, died Dec. 27, 1608. He studied divinity at St. John's college, Cambridge; afterward he turned his attention to the legal profession, and became clerk to a counsellor at law. Eventually, however, he returned to the university, and was chosen fellow of St. John's in 1560. In 1570 he was chosen Lady Margaret's reader of divinity, and while he occupied that chair he provoked the hostility of Sir William Cecil and Dr. Whitgift, by the constancy with which he advocated the Puritan doctrines and discipline; and in 1571, when the latter became vice-chancellor of the university, he was deprived of his professorship, and, in the following year, of his fellowship. He now repaired to the continent, where he became acquainted with the most eminent Puritan divines in the Protestant universities of Europe, and subsequently was chosen minister to the English merchants at Antwerp and Middleburgh. At the end of 2 years, at the solicitation of his friends, he returned to England, and published a second admonition to parliament in behalf of the Puritans. A protracted controversy with Whitgift, afterward archbishop of Canterbury, was the result of his publication, and Cartwright had again to expatriate himself to escape from his opponent. While abroad, he officiated as minister to English communities. In 1580 James VI. of Scotland offered him a professorship in the university of St. Andrew's, which Cartwright declined. He was imprisoned on his voluntary return, but was released through the influence of Burleigh and Leicester. Leicester made him mas-

ter of the hospital which he had founded at Warwick. He was again committed to prison at various periods, and did not obtain his liberty until 1592, when he was reinstated in his mastership of the Warwick hospital, and was again permitted to preach. His "Confutation of the Rhemish Translation, Glosses, and Annotations on the New Testament," was not published till after his death, in 1618. He was also the author of several other works.

CARUPANO, a town of Venezuela, on the coast of the Caribbean sea, finely situated at the opening of 2 valleys, in the province of Cumana, within a few miles of Cariaco. Its harbor is defended by a battery, and it has considerable traffic in horses and mules. Pop. about 8,000.

CARUS, KARL GUSTAV, a German physician and naturalist, born in Leipsic, Jan. 8, 1789. After pursuing the usual course of study in the gymnasium and university of his native place, he devoted himself to chemistry, with a view of rendering his knowledge useful in the workshop of his father, who was a dyer. He soon, however, left chemistry for medicine, and graduated as M. D., in Leipsic, in 1811. Engaged as teacher in the university, he was the first to deliver there a distinct course of lectures on comparative anatomy. In 1813 he was appointed to the French hospital established at Pfaffendorf, near Leipsic, and by his devotion to his patients contracted a severe illness. The following year, on the reorganization of the medico-chirurgical academy of Dresden, he was appointed professor of midwifery, and at the same time had the clinical direction of the lying-in hospital. In 1827 Carus resigned his professorship on being appointed physician to the king of Saxony, with the title of royal and medical councillor. He continued, however, to lecture, and in 1827 delivered a course of lectures on anthropology, and in 1829 on psychology, which added greatly to his previous reputation. In the latter year he attended Prince Frederic Augustus, the present king of Saxony, on his tour through Switzerland and Italy. Beside his professional and scientific labors, Dr. Carus is a painter of marked talent; many of his pictures are much esteemed by amateurs. The reputation of Carus rests mainly on his discovery of the circulation of the blood in insects, for which he received a prize from the French academy of sciences, and his contributions to the history of development in animals. His principal works are *Versuch einer Darstellung des Nervensystems, und insbesondere des Gehirns* (Essay on the Nervous System, and particularly on the Brain), Leipsic, 1814; *Lehrbuch der Zoötomie* (Manual of Zoötomie), with 20 plates engraved by himself, Leipsic, 1820; *Erläuterungs Tafeln zur vergleichenden Anatomie* (Explanatory Tables for Comparative Anatomy), 3 vols., Leipsic, 1826-'31; *Ueber den Blutkreislauf der Insecten* (On the Circulation of the Blood in Insects), Leipsic, 1827; *Grundzüge der vergleichenden Anatomie und Physiologie* (Principles of Comparative Anatomy and Physiol-

ogy), 8 vols.,

*Psychologie* (Leipsic,

sic, 1831; *Briefe*

(Letters on Landscape,

*Symbolik der menschlichen*

of the Human Form), 1853.

CARUS, MARCUS AURELIUS, a Roman emperor, born about A. D. 222, died 268. His father was an African, and his mother a noble Roman lady. He was proclaimed emperor by the legions, on the assassination of Probus, 261. He caused justice to be executed upon the assassins. He gained a signal victory over the Sarmatians, and prosecuted the war against the Persians. Undertaking the campaign in midwinter, and making a rapid march through Thrace and Asia Minor, he ravaged Mesopotamia, made himself master of Seleucia, and carried his arms beyond the Tigris, where he died suddenly in his camp.

CARVALHO, JOSE DA SILVA, a Portuguese statesman, born in Beira in 1782, died Feb. 1, 1845. He was a member of the regency and appointed minister of justice until 1823, when, on the downfall of the constitutional government, of which he was a foremost champion, he was obliged to resort to flight to England, where he remained until 1826, when he returned to Lisbon, but Don Miguel's success again compelled him to leave. Eventually he was named a member of the council of guardianship instituted by Don Pedro for the young queen Donna Maria, and succeeded in negotiating the first English loan for Portugal. Having accompanied Don Pedro to the Azores, he filled, on his return to Portugal, important offices, and became finance minister in 1831. In 1835 he retired with the Palmella administration, and was presently obliged to retire to England, where he remained until 1838, when a general amnesty was proclaimed.

**CARVALHO Y MELLO.** See **POMBAL**.

**CARVALLO, MANUEL**, a Chilian statesman, at Santiago in June, 1808. He received a liberal education; devoted himself from his youth to literary pursuits, and at the same time to the study and the practice of the law. In 1830 he became chief clerk of the congress of plenipotentiaries in his native town. He was also appointed chief clerk of the state council, and elected a member of the Chilian assembly of representatives. Afterward he was sent on a diplomatic mission to Washington, for some time he held the position of chargé d'affaires of Chili near the U. S. government. In 1835, on his return home, he devoted himself exclusively to the law, in which he attained eminence, and many of the more complicated cases in which he was engaged as counsel were embodied by him in a permanent publication. He is a member of the committee for reform of the Chilian codes, of the faculty of law and political sciences of the university of Santiago, but he chiefly excels as an international lawyer. In 1846 he resided again for some time as minister at Washington.

**CARVER, JOHN**, first governor of Plymouth colony, born in England, date unknown, died in 1621. He had quitted his country on account of religion, and had established himself at Leyden, whence he was sent to effect a treaty with the Virginia company concerning a colony in N. America. He obtained a patent in 1619, and proceeded to N. America in the ship *Mayflower* with 101 colonists. After a dangerous voyage they arrived at Plymouth, where he was unanimously elected governor. He managed the affairs of the infant colony with success, and exhibited great address in his intercourse with the Indians, but died within a few days after landing.

**CARVER, JONATHAN**, an American traveler, born at Stillwater, Conn., in 1782, died in London in 1780. He abandoned the study of medicine for a military life, and was in all the wars by which the Canadas came into the possession of Great Britain. At the peace he undertook to explore the interior of N. America, to open new channels of commerce. He crossed the continent to the Pacific, and returned to Boston in 1768, having travelled about 10,000 miles. Proceeding to England, he unsuccessfully solicited from the king requital of expenses, and aid in publishing his charts and journals. He was even commanded to deliver up his papers, now ready for publication, being the property of the government, and was obliged to repurchase his papers from the bookseller to whom he had sold them. Ten years afterward he published an account of his travels.

**CARY, COL. ARCHIBALD**, a Virginia patriot and statesman, born in Virginia about 1780, died Sept. 1786. He early became a member of the house of burgesses, where he ranked with the first intellects of the epoch. In 1784 he served on the committee which re-

ported the address to the king, lords, and commons, on the principles of taxation; and in 1770 was one of the signers of the "mercantile association," which pledged its members to use no British fabrics thereafter, the design being to resist by practical measures the encroachments of the government. In 1778 he was one of the celebrated committee of correspondence by which the colonies were united into one great league against parliament; in the following year he was a member of the convention which appointed delegates to the general congress; and he served with great distinction in the convention of 1776. As chairman of the committee of the whole, he reported the resolutions instructing the Virginia delegates in congress to propose independence, and from his lips fell the declaration of Jefferson, the bill of rights of Mason, and the first constitution of Virginia. When the state government was organized under this constitution, he was returned to the senate, where he presided with great dignity and efficiency. At this time occurred the incident with which his name is most generally connected. The scheme of a dictatorship had been broached, and without his knowledge or consent, Patrick Henry was spoken of for the post. In the midst of the general agitation Col. Cary met Mr. Henry's half-brother in the lobby of the assembly, and said to him: "Sir, I am told that your brother wishes to be dictator. Tell him from me, that the day of his appointment shall be the day of his death, for he shall find my dagger in his heart before the sunset of that day." The project was speedily abandoned. Col. Cary soon afterward retired to his estate of Amptill, in Chesterfield, where he died, greatly respected and beloved. His family was of noble extraction, descended from Henry Lord Hunsdon; and, at the time of his death, Col. Cary was himself the heir apparent of the barony. In person he was short of stature, but possessed great personal beauty. His features were small and delicately chiselled; his eye remarkable for a very peculiar brightness, as his portrait shows. He was a good representative of the former race of Virginia planters, delighting in agricultural pursuits, in blooded horses, and improved breeds of cattle, which he imported from England, and attended to with great care. In character he was a man of singular courage; his serene intrepidity shrunk from no peril, and counted no cost where his honor or rights were concerned. From this trait of his character he was called by his contemporaries "Old Iron," a name which still clings to him in Virginia, where his memory is held in high respect.

**CARY, HENRY FRANKS**, an English writer, born in 1772, died in Sept. 1844. He early distinguished himself by an original ode on the misfortunes of Poland, and having entered Oxford devoted himself with ardor to the study of the modern European languages. His translation into blank verse of the *Divina Commedia* of Dante has gained him celebrity among all

readers of the English tongue. This great work did not, however, attract much attention until Coleridge brought it into notice by his commendations. Cary also translated the "Birds" of Aristophanes, and some odes of Pindar. His continuation of Johnson's "Lives of the English Poets," and his "Lives of the Early French Poets," are meritorious productions; the latter were published anonymously in the "London Magazine." From 1826 he was assistant librarian of the British museum for six years. He published carefully revised editions of Pope, Cowper, Milton, Thomson, and Young.

CARY, Rev. Lorr, born a slave, near Richmond, Va., in 1780, died at Monrovia, Nov. 8, 1828. In his youth he became vicious and profane, but in his 27th year he was converted and joined the Baptist church. With the change in his character came the thirst for knowledge. Possessed of a high order of native talent, he soon learned to read and write, and after a time he began to preach to his countrymen with great acceptance. He succeeded in raising by extra work \$850, with which he redeemed himself and his 2 children from slavery. He was then employed in a tobacco warehouse at a salary of \$800, and subsequently of \$1,000 per annum. In 1815 he became much interested in Africa and in the establishment of missions there. When the journal of Messrs. Mills and Burgess, who had been sent out to explore the country and secure a site for a colony, was published, Mr. Cary read it with great interest, and in company with a friend, Colin Teage, determined to emigrate to Africa. He sailed accordingly in Feb. 1821, and was instrumental in the removal of the colonists from their first unhealthy position to Cape Mesurado, now Monrovia. Faithful, energetic, and intelligent, he was now the leader in the erection of cabins for the settlers, then felling trees, prescribing for the sick, preaching to his countrymen, or fighting bravely against the savages who had determined to exterminate them. Once, when the colonists had become dissatisfied with the course of the colonization society in regard to the tenure of their lands, Mr. Cary took sides with them against the agent, Mr. Ashmun, although personally his friend. It was a time of gloom, of doubt, of trial; but the calm, firm spirit of Ashmun rose above the gloom. Although aware that the colonists had some reason for complaint, he felt that their only safety lay in obedience to the company's orders until they could be modified, and that this could only be effected by appeals to their reason and judgment. He accordingly stated to them clearly and plainly the result of their continued refusal to obey the directions of the company, and demanded an immediate pledge of obedience from those who were willing to act with him. It is in the highest degree creditable to Mr. Cary, that seeing the evils which would follow insubordination, he came forward, and frankly proffered

his hand to Mr. Ashmun, saying as he did so, "I give the pledge, sir; I acknowledge my error, and cheerfully submit to the laws of the society. Henceforth, I stand by her side, so help me God!" Some 3 or 4 years later, when Mr. Ashmun found himself worn out by the incessant toil in that deadly climate, he left the U. S., in Sept. 1826, leaving the control of the colony in the hands of Mr. Cary. The explosion of a cask of powder in a building, where he was making preparations to repel an assault made by the natives, killed him.

CARYATIDES, in architecture, are columns or pillars which support a roof in lieu of columns. The story is that the inhabitants of Caryæ, an Arcadian village, joined the Greeks after the battle of Thermopylæ; after the defeat of the Persians the confederate Greeks destroyed Caryæ, put the male inhabitants to death, and enslaved the women. In commemoration of their infamy many are the representations of these women to support a roof, and heavy superincumbent weight.

CASA SANTA, the "holy house," is a small building, in which the Blessed Virgin is supposed to have dwelt at Nazareth. According to Catholic tradition, angels bore it away from Nazareth in 1291, and placed it near the coast of Italy, near Recanati. It was removed later it was removed 1,000 paces nearer to the sea. It changed its position again to the spot where the town of Loreto now stands, a noble lady named Lauretta, and the spot where the town of Loreto has been built. The house is 32 feet long, 16 feet broad, and 18 feet high, with a hemispherical roof. It has no foundations, is similar in color and texture to the rock of the cave in Palestine, and is surrounded by a wall. The interior is adorned with paintings in the sixteenth century style, now nearly effaced, and this circumstance is supposed to confirm the account given by historians that St. Helena advised its removal from Palestine. In the interior, formerly of mosaic gold work enriched with precious stones, but now of silver gilt and mosaic work, is the ancient statue of the Virgin of the cedar of Lebanon, and removed from Loreto simultaneously with the house. It was carried to Paris in Feb. 1797, restored by Napoleon I. to Pius VII., and by that pontiff enriched with precious stones, and carried back to Loreto, Dec. 8, 1802. Several apostolic constitutions set forth that the house of Loreto is that in which the Saviour became incarnate. It has ever been a favorite object of devotion for Catholic pilgrims.

CASABIANCA, Louis, a French naval officer and politician, born about 1755 at Bastia, died Aug. 1, 1798. He entered the naval service when very young, and distinguished himself by his prowess. Having adopted the principles of the French revolution, he was elected to the national convention; on the trial of King Louis XVI. he did not vote for death, but merely for imprisonment. He subsequently became a

of the council of 500; after which he inted captain of L'Orient, the flag-ship al Brueys, the commander of the fleet ok Bonaparte and his army to Egypt.

leet was attacked by the English in ou Aboukir, Casabianca fought most o the last, and was killed with his son, ears old, by the explosion of his ship.

NOVA, GIOVANNI GIACOMO DE SEIN- accomplished Don Juan of the 18th who travelled from land to land, cap- the hearts of women and fascinating of men, born in Venice, April 2, 1725, ienna in June, 1803. We hear first asanova family at the beginning of century, when Giacomo Casanova, rd of the Aragon house of Pala- a secretary of the king of Aragon, a sensation at Rome by eloping with His son Giovanni was expelled from 1481, on account of a duel, and joined

the expedition of Columbus. Marco Antonio, Giovanni's son, a poet, was expelled from Rome by Giulio de' Medici, against whom he had published a satire. His grandson, Cajetano Giuseppe Giacomo, led an adventurous life, which he crowned by turning comedian, and by marrying Zanitta Farusi, the beautiful daughter of a Venetian shoemaker. Cajetano and Zanitta were the parents of the subject of this notice, who, when only 10 years old, vindicated his birth by making love to Bettina, the pretty sister of the abbé Gozzi, under whose instruction he was placed at Padua. Implicated in a brawl between the policemen and the students of Padua, he was compelled to leave that city, and betook himself to Venice. His adventures there are described in his memoirs, and reveal the frivolous character of the Venetian society of those days. Having become notorious for his profligacy, he was finally thrown into the dungeon of Santo Andrea, but effected his escape, and, after wandering over various towns of Italy and Calabria, succeeded in finding at Morterano a prelate to whom he brought letters of introduction, which his mother had obtained for him, and who recommended him to his friends at Naples. They, in turn, supplied him with letters to Cardinal Acquaviva in Rome, who brought him into personal contact with Pope Benedict XIV., and this circle of acquaintance laid the foundation for his subsequent career. His devotion to the poetical Marchesa Gabrielli, his mental encounters with the literati (for Casanova was a person of culture and varied learning), his conversational triumphs in the high social circles of Rome, were all brought to a sudden close by his connivance in an elopement which gave offence to the marchesa, who requested Cardinal Acquaviva to dismiss Casanova, whom he employed as secretary. Although there was no resisting an order from such a quarter, the cardinal gave him a passport for Venice, and eventually he reached Constantinople, in company with the Venetian ambassador, into whose favor he had insinuated himself with his wonted grace. He was received with great distinction by Cardinal Acquaviva's friend, the pasha of Caramania, alias Count de Bonneval, who introduced him to Yussuf Ali, whose wife fell in love with him, while his daughter Zelmi was offered to him in marriage. He left Constantinople surfeited with presents and money, which he lost in gambling soon after his arrival at Venice in 1745, where he accepted a humble musical employment in the orchestra of the theatre San Samuele, in order to save himself from starvation. Here he fell in with the rich Venetian senator Bragadio, but was soon again compelled to remove to other places in order to escape the hands of justice. After figuring as a magician at Cesena, as a priest at Milan, and in various characters at Mantua, Ferrara, Bologna, Parma, and Venice, he made, on June 1, 1750, his first appearance in Paris. There his reputation had preceded him, and he was received with

great favor. All the *beaux esprits* and dissolute dames of the profligate capital lavished their attentions upon the hero of the thousand and one scandalous tales. The marshal de Richelieu became his bosom friend; the duchess of Chartres doted upon him. After 2 years in Paris, he joined his mother, who was then performing at the theatre of Dresden, and subsequently proceeded to Vienna, where he was received with the same eclat. On his return to his native city, however, July 25, 1755, he was lodged in the terrible dungeons of the council of ten. He gives in his memoirs a most entertaining but highly improbable account of the miraculous skill and audacity which he displayed in again effecting his escape. In Jan. 1757, he reappeared in Paris, where the dungeon episode added considerably to his notoriety. He now tried his hand at politics and financiering, and proposed a lottery, in order to restore the equilibrium of the French exchequer. A meeting was convened to deliberate on the subject. D'Alembert in his capacity of mathematician was invited to attend it. Casanova's persuasive power convinced the most sceptical minds of the infallibility of his project; it was actually adopted, but he did not remain to observe its development, being sent as a kind of government spy to Dunkirk. On his return to Paris, he met at the marchioness of Urfé's the famous adventurer, the Count de St. Germain, whom he subsequently found installed at the Hague. After failing in his various industrial speculations at Paris, Casanova went to Holland under the auspices of the duke of Choiseul, to contract a loan for the French government; while strange to say, St. Germain had received the same mission from the hands of Louis XV. himself. The two adventurers were well matched, but as they found the Dutch unwilling to advance any money, Casanova resumed his travels. At Roche he paid his respects to Haller, and at Ferney to Voltaire. At London he met the chevalier d'Eon, and was introduced to George III., but, implicated in a charge of forgery, left the English capital in a singularly hurried manner. At Brunswick the prince of Prussia helped him out of a pecuniary difficulty. His rencontres with St. Germain continued to be frequent and amusing. At Sans Souci he had an audience of Frederic the Great; at St. Petersburg of Catharine II. Prince Adam Czartorysky introduced him to the king of Poland. He returned to Vienna, but Maria Theresa would not receive him, and he departed for Spain. There his career forms one series of scandals and intrigues. In Barcelona he was put in prison, where he beguiled his time by writing a refutation of La Houssaye's "History of Venice." After recovering his liberty, he betook himself in 1768 to Aix, where he met Cagliostro. This meeting of the two great adventurers of the 18th century was full of interest. But Casanova's roving career was now drawing to its close. At a din-

ner of the met Count ed man, and precarious p librarian in t where he spent remaining 14 life. Casanova wrote a work on P translated the Iliad, and was the account of his imprisonment, and writings. But his literary fame *Mémoires*, which he wrote in French residence in Bohemia.

CASAS, BARTOLOME DE LAS, called to the American Indians, born Spain, in 1474, died in Madrid father accompanied Columbus 1st and 2d voyages, and on the latter of with him his son, then 19 years of that time had pursued his studies success at Salamanca. Bartolome the 3d and 4th voyages of Col. return to Spain he determined ecclesiastic, and entered the order cans, with a view of being missionary to the Indians. His offered till his arrival in 1510 where he celebrated the first ever been heard from a new world. Soon after, he was curacy in the island of Cuba, attention of Governor Velasquez by ence which his mildness and charity over the native population. His zeal into the interests of the unfortunate oppressed by their European conquerors. 1516 returned to Spain to obtain measures of redress. Cardinal Ximenes, sent out 8 Hieronymite the abuses complained of, but the commission not satisfying the desire, Casas, he soon returned again to stricter and more efficient regulations to save the Indians from the oppression which threatened them. If continued, Las Casas, who had been thriving and robust beneath the sun of Cuba, proposed the introduction of negroes to labor in mines and on sugar plantations to relieve the natives. The plan which he had suggested was quickly carried into effect by the monarchists, the traffic in negroes became a commerce, and the servitude of the natives only exchanged for that of the negroes. The failure and perversion of the plan formed the bold project of the king, under his own guidance, Charles V. the gift of 250 leagues of land for this purpose. This plan too, in despair he retired to a Dominican convent at St. Domingo. He went as missionary through the provinces of Yucatan, and into Peru. He returned to Europe to report on the situation of the Indians and to propose him new reforms. Charles V.

for his many labors, appointed him to the bishopric of Cuzco. Las Casas preferred a poor, and having declined this appointment, accepted the next year the bishopric of Chiapa, in Mexico, in a province destitute of pearls, or commerce; and at the age of 60, he left Spain for the 8th time. His behalf of the Indians provoked a hostile response from Sepulveda, an officer of the Spanish crown who undertook to justify the conduct of the conquerors. To defend himself Las Casas wrote his work upon the destruction of the Indies, in which contained many particulars of the cruelties by the colonists, and was translated into several European languages. He met with success in the administration of his bishopric, having refused the sacraments to those of the Spaniards who reduced the Indians to slavery, and upon himself not only the hostility of the Spaniards but also the disapproval of the Pope.

Abandoned by all, he returned finally to Spain in 1551, after having during 50 years labored in America his zeal and his virtues. He retired to a cloister, and devoted the remainder of his life to various compositions, one of the most valuable of which, his "General History of the Indies," has never been published.

**CASAS GRANDES** (Span. great houses), a town of about 4,000 inhabitants in Chihuahua, on the Casas Grandes or San Miguel river, about 100 miles from Llanos, and remarkable for a number of ruins, apparently relics of an aboriginal civilization. These ruins are found about half a mile from a modern town, partly on the declivity of a hill, and partly on the plain at its base. They consist chiefly of the remains of a large edifice, built entirely of adobe, or mud with gravel and formed into blocks 22 inches thick, and about 3 feet long. No stone has been used, and the portions that must have been constructed of wood have entirely crumbled away. The outer walls are almost all prostrate, except at the corners, and were probably only 1 story high; the interior walls are much better preserved, in height from 5 to 50 feet, and being 5 feet thick at the base. The upper parts of these, like the exterior walls, are generally fallen, leaving the corners to show above the rest. The portions remaining seem to indicate an original height of 6 to 8 stories, but they are so much decayed that it is impossible to discover where the beams were inserted. The doorways have the tapering form noticed in the structures of Central America and Yucatan. Over them are circular openings in the partition walls. The stairways were probably of wood, and placed on the outside. Clavigero, in his "History of Mexico," tells us that the building, according to popular tradition, was erected by the Mexicans in their infancy, and that it consisted "of 8 stories with a terrace above them, and without an entrance to the lower floor. The door for

entrance to the building is on the second floor, so that a scaling ladder is necessary." It is difficult to form a correct idea of the arrangement of the edifice, but its main features seem to have been 8 large structures connected by ranges of corridors or low apartments, and enclosing several court-yards of various dimensions. The extent from N. to S. must have been 800 feet, and from E. to W. about 250 feet. A range of narrow rooms, lighted by circular openings near the top, and having pens or enclosures 8 or 4 feet high in one corner, supposed to be granaries, extends along one of the main walls. Many of the apartments are very large, and some of the enclosures are too vast ever to have been covered by a roof. About 200 feet W. of the main building are 8 mounds of loose stones, which may have been burial places, and 200 feet W. of these are the remains of a building, 1 story high and 150 feet square, consisting of a number of apartments ranged around a square court. For some distance S. the plain is covered with traces of old buildings, the nature of which cannot now be determined, and for 20 leagues along the Casas Grandes and Llanos rivers are found artificial mounds from which have been dug up stone axes, corn-grinders, and various articles of pottery, such as pipes, jars, pitchers, &c., of a texture far superior to that made by the Mexicans of the present day, and generally ornamented with angular figures of blue, red, brown, and black, on a red or white ground. The best specimens command a high price in Chihuahua and neighboring towns.—On the summit of a mountain, about 10 miles from the ruins above described, are the remains of an ancient stone fortress, attributed to the same people who built the Casas Grandes, and probably intended as a lookout.—On the Salinas and Gila rivers, in the country of the Pimo and Coco Maricopa Indians, New Mexico, are ruins of like character and evidently identical origin, to which the same name is usually applied. The Indians call all such ruins "Casas de Montezuma." Of those on the Salinas little remains but shapeless heaps of rubbish, broken pottery, and the traces of several irrigating canals. On the Gila, however, there are 8 distinct buildings, all enclosed within a space of 150 yards. The largest measures 50 by 40 feet, and at a distance looks not unlike a square castle, with a tower rising from the centre. The southern wall is badly rent and crumbled, but the other 3 are nearly perfect, are roughly plastered over on the outside, and hard-finished inside with a composition of adobe. The material of which they are constructed is the same as that used in the Casas Grandes of Chihuahua. The walls are perpendicular within, but their exterior face tapers in a curve toward the top. One of them is covered with rude figures. The ends of the beams, which denote by their charred appearance that the building was destroyed by fire, are deeply sunk in the walls, and show 8 stories now standing. The lower

floor is divided into 5 apartments. There is an entrance on each of the 4 sides, but there are no windows except on the W. side, and no traces of an interior stairway. The other 2 buildings are much smaller, and one of them was perhaps merely a watch-tower. Both are badly ruined. About 200 yards distant is a circular enclosure, from 80 to 100 yards in circumference; probably intended for cattle. For miles around the plain is strewn with fragments of pottery.—The origin of these ruins is a subject of doubt. They were seen nearly in their present state by the early explorers of the country, and the Indians then assigned them an age of no less than 500 years. Mr. Squier supposes them to have been the work of the aboriginal race of the Moquis.

CASATI, GABRIO, count, president of the provisional government of Lombardy in 1848, born in Milan, Aug. 2, 1798, distinguished himself during the revolution by his patriotism and moderation. Advocating the union of Lombardy and Sardinia, he officiated from March to July 25, 1848, as one of the ministers of Charles Albert, and subsequently he presided over the Lombard *consulta* at Turin, until 1849, when Lombardy came again under the sway of Austria.

CASATI, PAOLO, an Italian Jesuit, born at Piacenza in 1617, died in Parma, Dec. 22, 1707, celebrated for having been the means of converting Christina of Sweden to the faith of Rome, and for his proficiency in mathematics and theology, of which sciences he was professor.

CASAUBON, ISAAC, a Calvinistic theologian and critic, born in Geneva, Feb. 8, 1559, died in London, July 1, 1614. His father was a French Protestant minister, and sent him at the age of 19 to Geneva to study Greek, where he soon so distinguished himself as a linguist, that on the chair of Greek becoming vacant in 1582, he was appointed to it, though only 23 years of age. This post he occupied for 14 years. Meanwhile he married Florence, the daughter of Henry Stephens, the celebrated printer and publisher, by whom eventually he had 20 children. Some domestic difficulty with his father-in-law, or the financial embarrassments in which he was involved by being surety for a friend, led him in 1597 to remove to the chair of Greek and belles-lettres in the university of Montpellier. Two years afterward, at the solicitation of Henry IV., he went to Paris to take a similar professorship in the university of France. But the jealousy of the Catholic party made the measure impolitic, and Henry finally appointed a Catholic to the chair, and made Casaubon royal librarian, with a salary of 400 francs per annum. At the conference of Fontainebleau (May 4, 1600), Henry constituted him one of the Protestant judges. The Catholic party predicted that Casaubon would finally renounce his Protestantism; but he died in the Protestant communion, though there is no doubt he was sometimes wavering in his faith. Chagrined that his Protestant reputation was thus

impaired, Casaubon determined to leave France and therefore availing himself of the occasion of Henry's death to get leave of absence from the queen, he accompanied Sir Henry Wotton to England. He was received with distinction, made prebendary of Canterbury, and some say also of Westminster, and received a pension of £200, which he lived 3 years to enjoy. He was buried in Westminster abbey. To the end of his life he spoke Latin as well as he did his mother tongue, and was the most critical Greek scholar of his age. His works are mostly philological and critical, many of them being annotated editions of the classics.

CASAUBON, MEXIC, an English divine, son of the preceding, born at Geneva, Aug. 14, 1599, died in Somersetshire, July 14, 1671. He accompanied his father to England; was appointed to the cure of Bleadon in 1624, and 4 years afterward was made prebendary of Canterbury, and rector of Ickham. He received the degree of D. D. at Oxford, 1636. Through his attachment to the Stuarts he lost both property and preferments during the protectorate. Cromwell, perceiving his talents, made frequent efforts to win him over to the cause of the commonwealth; among which was a solicitation to write a history of the war. Christina, queen of Sweden, offered him the superintendency of all the Swedish universities, but he persisted in living in retirement in England until the accession of Charles II., when his ecclesiastical preferments were all restored. He published in his lifetime 2 vindications of his father from the aspersions of his enemies. He believed in the existence of witches and familiar spirits, a faith which he endeavored to defend in a work entitled "Credulity and Incredulity."

CASCA, PUBLIUS SERVILIUS, one of the conspirators against the life of Julius Caesar. He was not a person, otherwise, of much note, and it is even doubtful whether his name would ever have been recorded in history, had it not been for his complicity in this deed. He had been attached to the Pompeian party, and had like many others of the dictator's slayers, submitted himself to Caesar after the battle of Pharsalia, and received a free pardon. It is stated by Plutarch, in his life of Caesar, that when Tullius Cimber, according to the preconcerted plan, gave the signal for the assassination by dropping the fold of his toga from his shoulder, Casca struck the dictator on the back of the neck with a short sword, or dagger, but failed to inflict either a deep or deadly wound, being under the influence of agitation, if not of fear, when delivering the blow. Caesar, on feeling the stroke, turned round, it is said abruptly, and caught the assassin by the arm, crying out in Latin, "What dost thou, villain Casca?" when Casca calling to his confederates in Greek, "Help, brothers!" the others rallied to his assistance, and completed the bloody deed. Of so small celebrity is this person, but for his share in this conspiracy, that history has not recorded the fate which befell him.

**CASCADE RANGE**, a chain of mountains part of Oregon, forming a continuation of the Sierra Nevada of California. It lies 100 m. from the Pacific, and runs in general N. and S. Its highest summits vary in altitude from 10,000 to 17,900 feet. The altitude of Mt. St. Elias, in Russian America, is generally supposed to be the highest in North America. The name of this range is derived from the cascades of the Columbia, which are formed where that river crosses the Cascade range.

**CASCARA** (Span. *cascara*, bark), is the name of that species of croton called *croton tiglium*, a small tree or shrub which grows in the West Indies and Bahama islands. It has a spicy, bitter taste, and is used as a cathartic. When burnt, it emits an odor so agreeable that smokers have sometimes mixed a quantity of it with their tobacco, but it is injurious when thus employed.

**CASCOBAY**, on the coast of Maine, lying between the 2 headlands, 20 m. apart, of Cape Casco and Cape Small Point. It contains several islands, which have become a favorite resort during the summer season.

**CASE**, in grammar, is the inflection or change of a noun which a noun receives, in order to show its various relations to other words in a sentence.

The name is derived from the Latin *casus*, thus indicating a falling off from the original state of the word. This inflection was common to the ancient languages, but in modern languages have renounced it. In languages which the Greeks and Romans used, the nouns were inflected by changes of termination are expressed among the moderns by prepositions, or by the change in the order of words. In the English language, and those of the continental languages, only the pronouns are inflected in form according to the relations they express. Those languages which have cases do not all have the same number. The Latins had 6, the Greeks 5, and the Romans 4. The prepositions were resorted to to express the relations which had no case appropriate to them.

**CASE**, by changes of termination are expressed among the moderns by prepositions, or by the change in the order of words. In the English language, and those of the continental languages, only the pronouns are inflected in form according to the relations they express. Those languages which have cases do not all have the same number. The Latins had 6, the Greeks 5, and the Romans 4. The prepositions were resorted to to express the relations which had no case appropriate to them.

**ACTION ON THE, OR TRESPASS ON THE**, a form of personal action, first used in the reign of Edward III., as a remedy for injuries which the forms then in vogue were defective, and receiving its name from the fact that the whole case of the plaintiff was set forth in the original writ. It is so comprehensive in scope as to lie wherever damages are done to a person or property, for which no other form of action affords a remedy. This form of action may be called a natural species of action, in distinction from those which are of a technical character, is retained wherever the law is simplified, and forms the basis of the codes governing the single form of action in the codes of New York and several other states.

**HARDENING**, a process of hardening the surface of small iron articles, by con-

verting this portion of them into steel. For this purpose they are placed in an iron case, together with animal or vegetable charcoal, and subjected to the process of cementation. The carbon absorbed does not, in the short time allowed for the operation, penetrate beneath the surface. From 2 to 8 hours is the usual time that the articles are exposed to a dull red heat; they are then taken out of the burnt bone-dust, or other carbonaceous substance, and further hardened by quenching them in oil or cold water. Sometimes they are left to cool in the case, and are afterward tempered. Prussiate of potash has in various ways been found a very useful material for affording its carbon to iron for producing steel. Being a combination of two atoms of carbon and one of nitrogen with one of potash, it offers no solid residue that interferes with the progress of the chemical change, or impairs the quality of the steel. In case-hardening, it is sprinkled or rubbed upon the iron heated to dull red, and this, after being put in the fire for a few minutes, is taken out and tempered in water. The process is a convenient one where small articles are to be exposed to much wear, these being easily made of soft iron, and then externally hardened. It is also conveniently applied to give a good surface to small articles which are desired to receive the high polish of which steel is susceptible.

**CASE SHOT, OR CANISTER SHOT**, consists of a number of wrought-iron balls, packed in a tin canister of a cylindrical shape. The balls for field service are regularly deposited in layers, but for most kinds of siege and naval ordnance they are merely thrown into the case until it is filled, when the lid is soldered on. Between the bottom of the canister and the charge a wooden bottom is inserted. The weights of the balls vary with the different kinds of ordnance, and the regulations of each service. The English have, for their heavy naval guns, balls from 8 oz. to 8 lbs.; for their 9-pound field-gun, 1½ oz. and 5 oz. balls, of which respectively 126 and 41 make up a canister for one discharge. The Prussians use 41 balls, each weighing ¾ of the weight of the corresponding round shot. The French had up to 1854 nearly the same system; how they may have altered it since the introduction of the new howitzer gun, we are unable to tell. For siege and garrison artillery, the balls are sometimes arranged round a spindle projecting from the wooden bottom, either in a bag in the shape of a grape (whence the name grape shot), or in regular layers with round wooden or iron plates between each layer, the whole covered over with a canvas bag.—The most recently introduced kind is the spherical case shot, commonly called from their inventor, the British general Shrapnell, shrapnell shells. They consist of a thin cast-iron shell (from ¼ to ½ inch thickness of iron), with a diaphragm or partition in the middle. The lower compartment is destined to receive a bursting charge, the upper one contains leaden musket balls. A fuse is inserted containing a carefully

prepared composition, the accuracy of whose burning off can be depended upon. A composition is run between the balls, so as to prevent them from shaking. When used in the field, the fuse is cut off to the length required for the distance of the enemy, and inserted into the shell. At from 50 to 70 yards from the enemy the fuse is burnt to the bottom, and explodes the shell, scattering the bullets toward the enemy precisely as if common case shot had been fired on the spot where the shell exploded. The precision of the fuses at present attained in several services is very great, and thus this new projectile enables the gunner to obtain the exact effect of grape at ranges where formerly round shot only could be used. The common case is most destructive up to 200 yards, but may be used up to 500 yards; its effect against advancing lines of infantry or cavalry at close quarters is terrible; against skirmishers it is of little use; against columns round shot is oftener applicable. The spherical case, on the other hand, is most effective at from 600 to 1,400 yards, and with a proper elevation and a long fuse, may be launched at still greater ranges with probability of effect. From its explosion near the enemy, by which the hailstorm of bullets is kept close together, it may successfully be used against troops in almost any but the skirmishing formation. After the introduction of the spherical case shot, it was adopted in almost all European services as soon as a proper fuse composition was invented by each, this forming the only difficulty; and of the great European powers, France is the only one which has not yet succeeded in this particular. Further experiments, accidents, or bribes will, however, no doubt soon place this power in possession of the secret.

**CASEMATES** (Sp. *casa*, a house, and *matar*, to destroy), in fortification, vaulted chambers under the main wall of a bastion with embrasures for guns. Though generally considered by writers as only protected batteries, they have in the United States been used as subterranean barracks even in time of peace. They must be bomb-proof, and distributed along the faces and flanks of the bastion to serve as chambers to the garrison in case of bombardment, but a regard for the health of troops has prevented all armies except the American from using them as barracks, except when compelled by the exigencies of war.

**CASERTA**, a town of Naples, capital of the province of Terra di Lavoro, situated in a fertile plain on the railway line from Naples to Capua, 17 m. N. E. of the former, and 6 m. S. E. of the latter city; pop. about 25,000. It has numerous churches, a convent, a military school and excellent barracks, and is noted for its magnificent royal palace and aqueduct, both constructed by Vanvitelli for Charles III. The palace contains a chapel, and a large theatre, adorned with columns from an ancient temple of Serapis. The gardens are supplied with water from a distance of 27 miles by means of a fine aqueduct.

The principal branch of industry consists in the manufacture of silks.—On the hills behind Caserta is **CASERTA VECCHIA**, a fortified town, the seat of a bishop and of a prince, and containing a splendid cathedral and other churches; it was once a place of great importance, but has been eclipsed since the foundation of Caserta. Both towns were founded by the Lombards.

**CASES**, **COUNT DE LAS**. See **LAS CASAS**.

**CASEY**, a central co. of Ky., area 350 sq. m.; pop. in 1850, 6,556, of whom 634 were slaves. It is traversed by Green river and the Rolling fork of Salt river. The surface is hilly and broken. The productions in 1850 were 511,416 bush. of corn, 9,041 of wheat, 81,797 of oats, 74,600 lb. of tobacco, 24,423 of wool, and 27,197 of flax. There were 14 churches, and 1,186 pupils attending public schools. The county was organized in 1806, and named in honor of Col. Wm. Casey, one of the first settlers of Ky. Capital, Liberty.

**CASHAN**, or **KASHAN**, an ancient and flourishing city of Persia, in the province of Irak-Ajeme, situated in a rocky plain, about 90 m. N. of Ispahan on the route to Teheran; lat. 34° N., long. 51° 20' E.; pop. about 30,000. It contains a royal palace, 30 mosques, 13 baths, and numerous bazaars. Beautiful silks, shawls, cotton cloths, and carpets are manufactured here; copper utensils are also made here, and the workers in gold and silver are noted for their skill. It has considerable trade in fruit.

**CASHIEL** (anc. *Carsiol*, the "habitation in the rock"), a city and parliamentary borough of Ireland, co. Tipperary, with a station on the Great Southern and Western railway, 73 m. S. W. of Dublin; pop. in 1851, 4,798. Part of it is well built, but it has a poverty-stricken appearance, is destitute of manufactures, and has been on the decline for several years. It contains an elegant cathedral and parish church, a nunnery, chapels, schools, barracks, a hospital, an infirmary, and court-houses. Its most interesting object is the famous "rock of Cashel," which rises abruptly from the plain outside of the city, and is crowned with the finest collection of ruins in Ireland. These consist of a round tower, a Gothic cathedral built about the 12th century, a monastery and a castle of about the same date, and a chapel of hewn stone, with a roof of the same material, built in the Saxon and Norman styles of architecture, and still showing marks of extraordinary beauty. These remains, which are visible at a great distance, are all within an enclosed area. At the foot of the rock are the ruins of Hore abbey and of a Dominican priory. Donald O'Brien, king of Limerick, and his nobles took the oath of allegiance to Henry II. here in 1172. Cashel was the ancient residence of the sovereigns of Munster, and is often dignified by the title of "the city of kings." In the civil wars following the rebellion of 1641, it was taken by Lord Inchiquin, and afterward by Cromwell.

**CASHMERE**, **CACHEMIRE**, **KASHMIR**, **KACHMIR**, **KASCHMIR**, or **KACHMIR**, a kingdom in the

art of Hindostan, almost enclosed by the Himalayas, which separate it from Tibet on the N. and E. from the British districts of Spiti and Lahoul and the Punjab on the S., and from the Punjab and the country on the W.; area estimated at 10,000 sq. m.; pop. at 750,000. It extends from lat.  $32^{\circ} 17'$  to  $36^{\circ}$  N., and from long.  $75^{\circ} 40'$  E., and includes the whole of Cashmere, the provinces of Jammu or Iskardoh, Ladakh, Chamba, and others.—The valley of Cashmere is in an oval form, shut in by lofty mountains, the summits of some of which are covered with perpetual snow. It is from 5,500 to 6,000 ft. above the sea, and the alluvial plain forms its bottom is 70 m. long, 40 m. wide, and about 2,000 sq. m. in superficial extent. The area of the whole valley is 4,500 sq. m. It is entered by several passes, 11 of which are practicable for horses. The highest of these is that of the Pir Panjal, has an elevation of 10,000 feet. The principal river is the Jhelum, which receives numerous tributaries from the mountains, and flows through the valley to a pass into the Punjab. Several small rivers are scattered through the valley. Thus the valley is irrigated, and fertilized by the rains, unlike those of most parts of India, the soil attains an extraordinary fertility, and returns of from 30 to 60 fold of the seed are obtained. Rice, the common food of the people, is the staple; wheat, barley, buckwheat, maize, and tobacco, are cultivated to great extent; cotton is found to flourish; esculents, kitchen herbs, and saffron are raised; and the lakes supply the poorer classes with a nutritious though insipid article. In the *singhara* or water nut, the seed of the *rapa bispinosa*, which is ground into paste, roasted, boiled, or eaten raw. About 1,000,000 of this nut are annually taken from the Anchar lake. Among the fruits are the pear, plum, apricot, cherry, and grape. Flowers of rare beauty, particularly the rose, are highly cultivated, load the air with perfume. Many of the forest trees attain great size, and towering among them are the cedar, the chunar, the poplar, the willow, the wild chestnut. The willow, maple, birch, pine, and white thorn are common. The valley has its grove of chunars and poplars, planted centuries ago by order of the emperors, and now forming one of the ornaments of the valley. The most valuable minerals are iron and limestone, both of which are abundant; copper, plumbago, and silver are also known to exist. The climate is temperate, and milder than in many parts of India, but the stillness of the midsummer air gives it a heat and oppressiveness scarcely to be compared with that from the range of the thermometer at 50° at noon in the shade, and the winter is sometimes severely cold. Snow falls frequently. The bulk of the inhabitants are Hindoos, speaking a Sanscrit dialect, with

a large admixture of Persian, in which latter tongue the records and correspondence of the government are written. There are 2 prominent sects, the Soonnites, and the followers of Ali; the former being the more numerous and regarded as orthodox. The Cashmerians are preëminent among Indian nations by their physical perfection. The men are tall, robust, well formed, and industrious; the women famous for their beauty and fine complexion. They are a gay people, fond of pleasure, literature, and poetry, but are represented by many travellers as peerless in cunning and avarice, and notoriously addicted to lying. They appear to be of Hindoo origin. At the beginning of the present century the population of the valley was 800,000, which has been reduced by pestilence, famine, and earthquakes to 200,000. In 1828 an earthquake destroyed 1,200 persons; 2 months later the cholera carried off 100,000 in 40 days; and in 1838 famine and pestilence committed still more frightful ravages. The chief towns are Serinagar or Cashmere, the capital, Islamabad, Shupayon, Pampur, and Sopur. The principal manufactures are the celebrated Cashmere shawls, gun and pistol barrels, paper, lacquered ware, and attar of roses.—The country was conquered by the Mogul emperor Akbar in 1586, by the Afghans in 1752, and by the Sikhs in 1819. It was included in the territory transferred by the latter to the British under the treaty of Lahore in 1846, and was immediately sold by its new owners to its present holder, Gholab Sing, for the sum of £750,000.

CASHMERE, by the French manufacturers called *Cachemire*, a textile fabric made of the fine wool of the Thibet goat. This animal is characterized by long, silky, straight, white hair, large ears, horns not spirally twisted, and limbs slender and cleanly formed. The wool had long been used by the natives of Cashmere in producing the elegant shawls with which the name of their kingdom was associated, before these became known in western Europe. It was not, indeed, until the campaign of the French in Egypt, when the general-in-chief of the army sent one to Paris, that the French public had an opportunity of admiring the wonderful delicacy of the fabric, the softness of the material, the harmony of colors, novelty of the work, and strangeness of the design. Its arrival is said to have created an immense sensation, and measures were immediately set on foot to introduce the manufacture into France.—In Cashmere the wool is received from Thibet and Tartary, and, after being bleached, is spun and dyed of various colors. The weavers, employed by the merchants at the rate of from 1 to 4 pice (nearly 8 to 12 cts.) a day, receive the yarns, and in their shops, or at looms in their own houses, proceed to weave them after the patterns ordered. Each loom is estimated to make an average yearly production of 5 shawls; but a single one of the finest shawls sometimes occupies the work of a whole shop, keeping 2 to 4 persons constantly engaged about it for an

entire year. The total number of looms in Cashmere, it is believed, is about 16,000. The shawls they produce are the great article of export of the country. They are sent to various parts of Asia, and in India they were first made known to the English. The process of weaving the shawls with variegated figures is conducted without the shuttle, each colored yarn of the woof being worked upon the warp with its separate wooden needle; and, as the work goes on exceedingly slowly, it is customary to divide it among several looms, and then join the pieces together. This is so skillfully done that the seams are not detected. As the pattern is worked, the right side is the under one upon the frame, and is not seen by those who work it upon the upper or rough side. The shawls are made single and in pairs, either square or long. The former measure from 63 to 72 inches on a side, the latter 126 inches by 54. To work a single long shawl without a seam, and of the finest thread in the warp as well as the woof, in the most elaborate pattern and exquisite colors, would require the labor of about 3 years; and as in this time the colors are likely to change, and the fabric to receive injury from worms or otherwise, such shawls are rarely attempted. The fine shawls are more usually made upon 12 different looms for a pair, and when completed, at the expiration of 6 or 7 months, are worth in Cashmere from 1,200 to 2,000 rupees, or from about \$500 to \$800. The most expensive shawls sold in London or Paris are stated to have brought about \$2,000.—In the year 1819, M. Jaubert, under the auspices of the French government and at the expense of M. Ternaux, succeeded in bringing some of the goats to France. These were a cross between the original Thibet and a Tartar variety, and were of a comparatively hardy constitution. They were placed by M. Ternaux at his villa of Saint Ouen, near Paris, where they gradually increased in numbers, so that 4 were afterward obtained by Mr. Taylor, of Essex in England; and from these in 1833 the number had increased to 50. The down they furnished proved, however, to be too little in quantity to be of value; but by crossing the breed with the Angora goat, the downy product was largely increased, and it proved, moreover, to be of a long, silky quality, admirably adapted for shawls. With the wool obtained from these goats and that imported from Thibet through Kasan, capital of a Russian province on the Volga, the French maintain the extensive manufactures they have established of shawls made principally of this material. To imitate the genuine cashmere successfully greatly taxed the skill of their manufacturers; and though in Paris shawls have been produced like those imported, it is found more profitable to limit the manufacture to somewhat similar but more easily woven fabrics. The real cashmere is made by a very complicated process, which requires not only as many yarns in the woof as there are colors in the pattern, but also as many little

shuttles or pirns (like  
filled with these yarns  
repeated in the b  
skilful use of these  
licated with variety of colors,  
precisely alike on both sides. This  
have also done in their imitations of  
mere. But the principal articles of  
they manufacture are the so-called Fr  
mere shawls, in which the 2 sides are  
but on one side they have the exact app  
of the cashmere. They are made in  
the use of the draw-loom, or, which  
of the jacquard, with as many as  
colors in the design. These are thrown  
the warp as required; but being  
them brought into play only at 1  
threads remain floating loose on the back  
are at last trimmed off. Their felting pro  
prevents their coming out, but the ends con  
tinue visible on the wrong side. The process  
saves labor, but wastes material; the waste is,  
however, worked up in other fabrics. In the  
Paris-made articles the warp and woof are both  
of pure cashmere down. The shawls are mos  
ly square, of from 71 to 76½ inches on a side,  
and of the value of 220 to 500 francs. They  
have seldom less than 8 colors, commonly  
10 or 11, and sometimes 14 and 15. The long  
shawls in pure cashmere ought to measure from  
59 to 63 inches in breadth, and from 141½ to  
149½ inches in length. Their price is from 300  
to 700 francs. But there are also 2 varieties  
made at Paris, which differ somewhat from the  
above. One, called the Hindoo cashmere, has  
the warp in silk, and the rest is pure cashmere  
down. One or two colors less are employed,  
which reduces the price to 180, and from this  
to 120 francs. The other is called the Hindoo  
wool shawl. In this the warp is also silk, and  
the rest is of wool more or less fine in quality.  
This article is much more largely required than  
the others. The value of its annual production  
is reckoned to be from 12 to 15 millions of  
francs. Lyons leaves to Paris the manufacture  
of the pure cashmere goods, but successfully  
competes in the production of the pure wool  
Hindoo article. The wool employed rivals in  
softness and fineness that of the Cashmere goat.  
But the most important of the fabrics of Lyons  
is the so-called Thibet shawl, made of a mixture  
of wool and floss silk. In the manufacture of  
these and other varieties of shawls it is estimat  
ed that there are in Lyons 4,000 looms, each  
of which when in operation requires the atten  
tion of 3 persons. Nismes and Rheims have also  
each a factory which produce similar articles at  
great economy and at lower prices than those of  
Lyons and Paris. This important branch of  
industry is altogether the direct result of the  
efforts made to imitate the Cashmere shawl,  
first known in Paris during the present century.  
—Dr. J. B. Davis, of Columbia, S. C., while  
employed, a few years since, by the Turkish  
government, in experimenting on the growth  
of cotton in the Ottoman empire, succeeded in

9 pure breed Thibet goats, which he took to his native state, from whence they have been introduced into Tennessee, where they will thrive. In 1857 the wool raised in Tennessee brought \$8 50 per lb., the purchasers in New York proposing to send it to Scotland, where it was manufactured there into shawls.

CASHNA, a country of interior Africa, lying between Hausa and Bornoo, and separated from the Niger. Its capital is of the same name and is situated in lat. 13° 10' N., and 10° 50' E. Cashna is a mountainous but very fertile district, and produces abundantly barley, wheat, senna, and the grape. It maintains a communication with north Africa, by a caravan starting from Fezzan, and passing Assuani, Ghatt, and Agadez, reaches in 60 days the capital of Cashna, and in 5 days more the river Niger and thence proceeds to the S. even as far as the gold coast. Its principal exports are cotton, slaves, and dyed goat-skins; its woollen, cutlery, mirrors, and toys.

CASIMIR, or KAZIMIERZ, the name of several monarchs of Poland. I. The son of Miecislav II., and of Rixa, a German princess (died 1058).

After the death of his father, he ruled the country as regent; but the influence bestowed upon her own countrymen, and his ill conduct, caused an outbreak of national hatred, before which Rixa fled to Germany. Casimir followed her. Poland, left without a ruler, became a scene of the wildest anarchy and lawlessness; the lately established church had also to suffer greatly from persecutions. Profiting by this state of affairs, the Bohemians made an incursion into Poland and advanced as far as Gnesen, whence they carried away the body of St. Adalbert, patron of the Poles (ojciech), or, according to the relation of the priests of the place, the cunningly substituted the body of another man. Casimir was called by his countrymen from Germany, where he was living in quiet retirement, and with exercises of religious piety, gained him the surname of "the monk."

Assisted by Henry III. of Germany, he re-established his authority, and restored Christianity and a regular administration of justice, regained Masovia, gained Breslau and other cities from the Bohemians, and was honored with the title of Restorer of Poland. His wife was Dobrogniewa, sister of Jaroslav, the prince of Kiev; his successor Boleslaw Bold, his eldest son. II. THE JUST, born 1114, died 1194. He was the youngest of the sons of Boleslaw III., or Crooked Mouth, whom this monarch divided Poland, and he recovered the reunited country after the death of Mieczyslaw III. the Old (1177). He is highly renowned for his personal virtues, as well as for the introduction of laws defending peasants against the nobles and officers of the court. Under him the Polish senate was organized, consisting of bishops, palatines, and senators. He made successful expeditions into Prussia, Halicz, and Lithuania. III. THE

GREAT, born 1209, died 1279. He was the son and successor of Wladyslaw Lokietek (the Short), who had restored the union and the power of the long distracted kingdom. While still a prince, Casimir displayed his talents as governor of Great Poland, as well as his bravery in the wars of his father against the order of Teutonic knights, but also exhibited habits of great dissoluteness. In 1288 his father bequeathed him his throne, with the advice not to enter into any treaty with the Teutonic knights; but the inclinations of the young king were for peace, and he soon concluded a treaty, in which the knights ceded the districts of Kujaw and Dobrzyn, but gained Pomerania. To secure peace from the kings of Bohemia, he sacrificed to them the rich and valuable province of Silesia for the resignation of their claims and pretensions on Poland. Dissatisfied with his acts, the warlike nation sought redress for their grievances from the Teutonic knights at the court of Rome. The pope gave a favorable decision, commanding the knights to restore all the Polish districts, and to rebuild the destroyed churches; but the knights, trusting in their swords and in the aid of the emperor, scorned the bull, and maintained their conquest. In the meanwhile Casimir had strengthened his reign by salutary and peaceful reforms, as well as by the erection of numerous castles and fortifications. The adoption of his nephew, Lewis, son of Charles Robert, king of Hungary, as successor to the throne of Poland, confirmed by the assembly of the nation at Cracow (1289), secured the alliance with Hungary. In 1240 the death of Boleslaw of Masovia and Halicz, who died without progeny, offered a favorable opportunity for the annexation of Red Russia, which was easily executed in two successful campaigns. A consequence of these was an incursion of the Tartars (1241), at the summons of certain Russian princes, who pretended to have been wronged. Casimir fortified and defended the line of the Vistula, and by the speedy retreat of the invaders, Poland happily escaped total destruction. In 1244 some difficulties, caused by the dukes of Silesia, brought about a short war with the king of Bohemia, which was begun by the conquest of Silesia, and ended with the acquisition only of Fraustadt. Subsequently parts of Lithuania, Masovia, and Volhynia were added to Poland. But greater and more glorious were the successes achieved by Casimir in time of peace. The diet of Wislica (1247) sanctioned a double code of laws for Great and Little Poland, digested by the ablest men of the country, based in part on the ancient statutes of the nation, and in part on the German, or the so-called Magdeburgian institutions, according to which the commercial cities were governed. The rights of both nobles and peasants were determined and secured, and so great was the zeal of Casimir in defence of the latter against the former, that he was called the king of the peasants (*król kmiotków*). No less great was his ardor and activity in promot-

ing industry, commerce, arts, and sciences (particularly proved by the foundation of the university of Cracow), and in adorning and strengthening the country with buildings for public use and defence; and thus he deserved the remark of an ancient historian, that he inherited Poland of wood and left it of stone. Agriculture, industry, and general wealth gradually increased under Casimir; and the riches, pomp, and liberality of the state were displayed in an astonishing way on the occasion of the marriage of his granddaughter with Charles IV., emperor of Germany, which was celebrated for 20 days at Cracow, in the presence of Lewis king of Hungary, Peter king of Cyprus, Waldemar king of Denmark, and a great number of dukes and other distinguished guests. But his reign had also its shades: unhappy marriages; love affairs condemned by the people and the church; an excommunication by the archbishop of Cracow; a deadly revenge taken on its innocent announcer; the subsequent humiliation of the king by the pope; and a great defeat by the Wallachians. A fall from a horse ended the life of the most popular monarch of Poland.—Among the objects of the love of Casimir was the Jewess Esther, the heroine of so many romances, by whom he had several children, and who is supposed to have contributed greatly to the humane protection which he and his laws bestowed on her people in Poland, in the time of most barbarous persecutions in other parts of Europe. IV. Born 1427, died at Grodno 1492, was the son of Wladyslaw Jagiello, and brother and successor of Wladyslaw III., called Warnenczyk, from his defeat and death at Varna in 1444. Casimir was at that time grand duke of Lithuania, and accepted, but hesitatingly, the call to the throne of Poland. His long reign is remarkable for several diets held at Lublin, Piotrkow, etc.; for a successful war of 14 years against the Teutonic knights, terminated in 1466 by the peace of Thorn, which gave to Poland the western part of Prussia and the suzerainty of the eastern, and for the subsequent long period of general prosperity, luxury, and relaxation of the national spirit. The introduction of the Latin language into the schools and public life of Poland dates particularly from this reign. Of the 6 sons of Casimir, one was elected king of Bohemia and Hungary, three, John Albert, Alexander, and Sigismund, succeeded each other on the throne of Poland, one became a cardinal and one a saint. V. See JOHN CASIMIR.

CASINO, or MONTE CASINO, a celebrated Benedictine abbey, established by St. Benedict in 529, upon the mountain of the same name, in the Neapolitan province Terra di Lavoro, rising over the town of San Gerinano, the ancient Casinum, in former times the seat of a famous castle, and of a temple of Apollo. The beauty of the spot attracted many visitors, and the medical skill of the friars many invalids to the abbey, while at the same time pilgrims resorted there from all parts of the world, as the Benedictines were deemed to possess miraculous

balms derived from the abbey pre as its inmates published a variety of rian, Luigi Tosti, published in *Archivio Casinese*, and in 1841-'48 *Badia di Monte Casino*.

CASPIAN SEA (called by the I of Astrakhan, anc. *Mare Caspium*; Gr. *Κασπία θάλασσα*), an inland between Europe and Asia, lat. N., long. 46° 48' to 55° 25' E. from N. to S., 760 m.; g m.; average breadth about 000 sq. m. It is bounded N. by Russia, S. and S. W. by Toorkistan. It has few bays, on the Asiatic side, Emba bay, Karasoo inlet, Manghishlak gulf, Kenderlinsk gulf, Koolet Balkhan bay; on the European Agatch and Kooma gulfs, and indentations. At the southern ex sea is Astrabad bay, and from Emba bay at the north-east shore extends nearly in a Emba river, which enters the name by several mouths, and most the only considerable river receives on this side, though the O which now enters the sea of Aral, have once flowed into it. On the basin is far more extensive. The Volga, the Terek, and the Koor here pour waters into it, and most of them are bringing accumulations of sand, which instances, as at the mouth of little islands, projecting seaward. The shores are thus access, and in the northern and no parts the depth of water for 2 or land is only a few feet. All the coast, as far S. W. as the Soul formation; thence S. to the peninsula it is of tertiary formation, broken by sional carboniferous strata; and around the S. extremity of the are low and sandy, with lofty hills background. On the E. and S. E. is taceous subsoil, covered with the surface, with the exception of being flat. In fact, the coast is low, that most parts are overflowed wind sets in strongly from the open Naphtha, or petroleum, is found particularly on the peninsula of the island of Naphthalia, in the The waters are not so salt as those owing to the immense volume poured into the sea by the rivers. They are very deep remarkably shallow near the the southern part. The sea has no outlet, the carried off wholly by ordinary changes in its level

never explained; according to native account, the surface rises and falls several feet in a period of about 80 years. It has long been known that the level of the Caspian is lower than of the ocean, and in 1812 an attempt was made by Engelhardt and Parrot to ascertain the difference by a series of levellings and barometrical measurements across the Caucasian mountains to the Black sea. Measurements were made in 2 places, one of which made the Caspian 100 feet lower than the Black sea, and the other 301 feet lower. A survey made by the Russian government in 1836-'7 proved the difference of level to be 84 feet. Sturgeon, salmon, belugas, and seals are taken in great numbers, giving employment to nearly 100,000 persons. Nearly 100,000 seals, 1,000 lbs. of roes, and 20,000 lbs. of isinglass, produce of 700,000 sturgeons, are taken every year.—We have little knowledge of the ancient commerce of the Caspian. About the middle of the 13th century much of the trade of Europe with India passed over it, Astrakhan then, as now, its chief port. On the fall of Constantinople by the Turks, commerce was forced into other channels. In 1560 an English company made a fruitless attempt to render it a channel of commerce with Persia and Turkestan. Peter the Great had it explored by Dutch navigators, partly in the view of founding stations for the Russian trade on the Persian seaboard, but his project was not carried out. No Russian conquest was made on the Caspian sea until the time of Catharine II., and it was not until still more recent periods that Russia succeeded in obtaining control over its trade. The following table shows the shipping movements in its waters during 5 years from 1851 to 1855 inclusive:

	Entrances.	Clearances.
1851.....	227	305
1852.....	273	666
1853.....	169	292
1854.....	181	311
1855.....	302	305

Total ..... 1,151 ..... 1,779

On an average in 5 years of 230 entrances, and clearances of foreign vessels, beside the many vessels engaged in the coasting trade. The largest class of vessels by which the Caspian sea is navigated, of which there are about 100 sail, carry rarely less than 90 or more than 150 tons, are called *schuyts* by the Russians, and are built of the timber of the forests that bring breadstuffs down the Volga to Astrakhan. Another class of vessels of superior quality, of which there are about 50, range from 70 to 140 tons, and are called *ships*. Beside these 2 classes of vessels, there are a great number of small craft, and a charter for a Caspian steamboat navigation was granted by the Russian government in April, 1858. The principal ports are Astrakhan and Bakoo. The Russian fleet in the Caspian sea consists of 4 brigs, 2 steamers, and other vessels; total, 13 vessels.—Dureau-Vielleville's *Géographie physique de la mer*

*noire*, Eichwald's *Reise auf dem Kaspischen Meere und in den Kaukasus*, Hommaire de Hell's *Les steppes de la mer Caspienne*, and the *Beschreibung*, published by Sawitsch and Sabler, giving their survey of the respective elevations of the Black and Caspian seas (St. Petersburg and Leipzig, 1849, in German), contain valuable information on the Caspian sea.

OASORIA, a town of Naples, pop. 7,924, the birth-place of Pietro Martino, the painter. It has 4 churches, and produces quantities of silk.

OASPARI, KARL PAUL, a German commentator on the Old Testament, born Feb. 14, 1814, at Dessau. After studying at Leipzig and Berlin, and graduating in 1844 as licentiate in theology at Königsberg, he became, in 1847, teacher at the university of Christiania. In conjunction with Delitzsch he is publishing "An Exegetical Hand-book of the Prophets of the Old Testament," and "Biblical, Theological, and Apologetic-Critical Studies." To the former work Oaspari contributed in 1848 the "Expositions of the Prophet Obadiah," and to the latter work in 1848, "Contributions toward an Introduction to the Book of Isaiah, and the History of the Times of Isaiah." In 1849 he published a treatise on the "Syrio-Ephraimitic War under Jotham and Ahaz," and in 1851 on "Micah and his Book." He is a member of the committee for revision of the Norwegian translation of the Bible. He has published an edition, with a translation, commentary, and glossary, of the *Enchiridion Studiosi* of Bohaeddin; also a *Grammatica Arabica*.

CASQUE, the head-piece or helmet of the ancient Greeks and Romans. The origin of the word is not well ascertained, but is, perhaps, referable to the Latin *cassis*, the term for that species of helmet the basis of which was metal, as opposed to *galea*, the original signification of which is a leathern skull cap; although the words, at a later date, were confounded and used indiscriminately to signify the armor for the head, of whatever form or material. The casques of the ancients were of many forms, from the simple bowl-shaped skull cap, without either peak to shade the face or guard for the neck behind, to the elaborate crested helmet, with cheek-pieces, neck-plate, and visor covering the face of the wearer. The latter appendage was not movable, so that it could be raised or depressed at pleasure, but was a solid portion of the helmet, and was made to cover or expose the features, by thrusting the whole helmet backward or drawing it forward. In the latter case, the crown of the helmet fitted closely on the skull, and the fore part, which protected the whole face, having perforations to correspond with the eyes and a long perpendicular slit extending downward from these, on either side of the nasal, or plate for the defence of the nose, was drawn down to the chin of the wearer, giving complete protection, and concealing the countenance so absolutely that the wearer could not be recognized. In the former

case, the crown was thrust back so far that it projected from the base of the skull behind, with the crest standing out horizontally backward, and the visor, or face-piece, resting flatly on the crown, so as to leave the features entirely exposed. The shape of this helmet and the mode of wearing it are, perhaps, best explained by saying that, in form, it exactly resembled a lady's cottage bonnet; that the ordinary mode of wearing it was the present fashion of putting it quite back off the head; while the mode of guarding the face was what it would be, if the real crown of the bonnet sat flatly on the top of the head, and the fore part were pulled down perpendicularly over the nose. It does not appear that these helmets were ever worn actually in battle, at least not in the second position; although some persons have supposed that the helmet of Aidoneus, which Minerva wore when she mingled in combat with mortals in the Trojan war, and which had the property of rendering its wearer invisible, was of this fashion. They were, however, certainly worn by the gladiators in the later ages of Rome; and specimens were found at Pompeii, something resembling the rudest form of the visored helmet of the 1st and 2d crusades. The ancient casques were ordinarily made of bronze, often of exquisite workmanship, with elaborate sculptures and designs in high relief, especially on the crown or head-piece, the cheek-pieces, *bucculae*, and the cones, or ridges, which supported the crest of waving horsehair. This was often dyed crimson, but sometimes left white or black. The cones were sometimes 3 or 4 in number, and fashioned into the likeness of sphinxes, dragons, or lions. A helmet of Minerva, on a fine antique gem, shows 4 parallel crests, each supported by a prancing centaur. According to Homer, casques were often made of the precious metals, or at least overlaid with them. Steel does not appear to have been in use for the fabric of ancient armor, or, until a comparatively recent period, even for that of offensive weapons. The sword-blades and spear-heads of Homer are all of brass, *χαλκος*, whatever mixture that word represented, probably copper hardened with tin; and it is not until Æschylus wrote that we find steel, *χαλυσ*, and iron, *σιδηρος*, used as synonymous for the sword. The word casque is used poetically in reference to all helmets, even to those of the middle ages, when it is applied to the whole covering of the head taken together without reference to parts, as the *cervelliere*, *avantaille*, beaver, and other appendages. The casque of the Roman legionary soldier was of bronze, open, not protecting the face; but it had a peak to cover the brow, another to guard the nape of the neck, cheek-pieces hinged on to the casque and connected by a clasp under the chin, and either a crest or a plume of 3 tall erect, black and scarlet feathers. This was the fashion, as described by Polybius, and in vogue during the Punic wars.

CASS, the name of counties in several of the

United States. I. A

sq. m.; pop. 18,564.

It is drained by the E. river.

W. co. of Iowa, recently erected; area 1,000 sq. m.; pop. in 1856, 815. It is traversed by the Des Moines river, an affluent of the Mississippi. Comparatively little of the land is under cultivation. The productions in 1856 were 16 bushels of wheat, 40,013 of corn, 100,000 of oats, and 13,501 lbs. of butter. E. central co. of Minn., situated near the mouth of the Mississippi; area 11,000 sq. m.

included in the census of 1850, and contained very few civilized inhabitants. Several small lakes are scattered over its surface. Pine and other timber is abundant, and is exported in considerable quantities.

Lewis, an American statesman, born in New Hampshire, Oct. 9, 1782, was the eldest son of Jonathan Cass. Both his father and mother were of old New Hampshire Puritan descent. His father, at the age of 19, had enlisted as a private soldier in one of the regiments of the New Hampshire militia immediately after the battle of Lexington. He was present at the battle of Bunker Hill, and, having reenlisted, continued to serve in the New Hampshire militia during the whole revolutionary war, the course of which he rose to the rank of captain. He was recommissioned with the rank of major in the army organized after the adoption of the federal constitution, and was promoted to be a major. While he was employed in the military service in the north-west of the Ohio, his family remained at Marietta; and Lewis, at 10 years of age, attended the academy at that place, where he pursued his studies with diligence and success.

In that year Jonathan Cass removed to Wilmington, Del., where he was employed for some months in his military career, and where young Lewis found employment as a teacher. His father, meanwhile, made up his mind to resign his commission, and to settle in the West, induced his son to follow his fortune also in the same direction. Leaving the Ohio from Pittsburg in a flatboat, the only means of conveyance, they landed at Marietta, the pioneer settlement of western Ohio, in Oct. 1800. The father accompanied with his family to a tract of land in the Muskingum near Zanesville, which was granted to him as military bounty, but young Lewis remained at Marietta, where he entered the study of the law. He was admitted to the bar in Dec. 1802, and soon after established himself at Zanesville, where he gradually acquired a large practice. In the summer of 1806 he married Elizabeth Spencer, whose father, then on the Virginia side of the Ohio, in 1793, had emigrated from Lansingburg, in New York. Shortly after his mar-

riage Mr. Cass was elected a member of the Ohio legislature, in which body he took a seat in December of the same year. The very first business that came up was a special message from Gov. Tiffin, based on communications made to him by President Jefferson, through a special agent, in relation to Burr and his designs, about which President Jefferson was greatly alarmed. This message, received in secret session, was referred to a committee of which Mr. Cass was a member. He drafted a bill, and the committee reported a bill, which he conducted through the legislature, where it encountered considerable opposition, authorizing the governor to call out the militia and to break up any unauthorized military preparation which might be on foot. Under this act such of Burr's boats as were being built in Ohio, and his provisions collected in that state, were seized, and the Ohio part of the expedition was thus broken up. A legislative address, drafted by Mr. Cass, protesting attachment to the union, which Burr was suspected of a design to divide by the Alleghenies, drew out a highly complimentary reply from the president, who soon after acknowledged Mr. Cass's services by an appointment as U. S. marshal for Ohio. The emolument of this office was but trifling and its duties limited, and Mr. Cass still continued to practise law as before; but this federal office disqualified him from sitting any longer in the Ohio legislature. The lower branch of that legislature, not long after, undertook to impeach 2 of the judges for having decided that a certain state law was unconstitutional and void. Mr. Cass appeared on the trial as one of their counsel, and by his able and successful defence added to his reputation as an advocate.—The hostile position of the western Indians and the growing difficulties with Great Britain led, in April, 1812, to the enrolment of 8 regiments of Ohio volunteers. Mr. Cass, who sympathized strongly with the popular feeling, was among the number, and was chosen colonel of the 8th regiment. These 8 regiments, about 1,200 strong, together with some 800 regulars under Col. Miller, constituted the army with which Gen. Hull was expected not only to protect Detroit from the British and Indians, but to invade and conquer Upper Canada. After a march of more than 200 m. through a swampy wilderness which then intervened between the frontier settlements of Ohio and those of Michigan, the troops reached Detroit early in July, war with Great Britain having meanwhile been declared. On July 11 they marched into Canada. The proclamation issued on this occasion was written by Col. Cass, for whom, too, the honor is claimed of having been the first man who, in the war of 1812, stepped in arms upon the British soil. He also commanded in a skirmish, on the 17th, in which the first blood was shed, the British being driven from a bridge across the Aux Canards river held by their outposts. Hull, however, alarmed at his isolation, and exaggerating the numbers of the

enemy and the danger of his position, soon recrossed to Detroit, and on Aug. 16 terminated the campaign, to the mortification of his officers and men, by surrendering his army, and Detroit and the territory of Michigan along with it, to the British general Brock. At the moment of surrender Col. Cass was absent with a detachment sent to relieve a provision train, the approach of which had been stopped by the enemy. This detachment, however, was included in the capitulation, and being without provisions, was obliged to yield. Col. Cass, stung with mortification at this unexpected turn of affairs, when asked to deliver up his sword, indignantly broke the blade and threw it away. By the terms of the capitulation the Ohio volunteers were dismissed on their parole not to serve again till exchanged, and Col. Cass, at the request of his fellow-soldiers, hastened to Washington for the purpose of vindicating them from any responsibility for this disastrous termination of the campaign. His report, anticipating that of Hull, who remained a prisoner with the British, was the first official account of the campaign given to the public. Col. Cass was exchanged in Jan. 1818, and about the same time was commissioned as a colonel in the regular service. His regiment was enlisted and ready by March, when he was further promoted to the rank of brigadier-general. He joined Gen. Harrison's army in July; and, Perry's victory on Lake Erie having opened the way, he bore his share in the pursuit of Gen. Proctor and the victory of the Thames. He was then placed in command at Detroit, and shortly after was appointed governor of Michigan. He now resigned the office of marshal of Ohio, which he had still continued to hold, and, not long after, his commission in the army also; having first, however, attended the court-martial for the trial of Hull. His testimony before the court, as his report had done, bore hard on that unfortunate commander, and has been at times a good deal criticized.—Though Detroit had been settled for more than a century, the territory of Michigan was yet in its infancy. It still remained what it had been from the beginning, little more than a station for Indian trade. The white inhabitants, mostly of French descent, did not exceed 5,000 or 6,000. Not a foot of land had ever been sold by the United States, the small tracts in private possession being held under French and English grants, often of doubtful validity. The settlements had neither church, schoolhouse, courthouse, gaol, bridge, nor scarcely a road, and the inhabitants had been reduced by the pending hostilities to a state of great destitution. The British had been driven away, but the neighboring Indians still remained hostile. The treaty of Greenville in July, 1814, at which Governor Cass aided, reestablished peace with the Ohio Indians; but it was not till the termination of the war with Great Britain that the territory became entirely secure from Indian attack. In June, 1815, Governor Cass removed his family to Detroit, and

the next:

a tract of 100,000  
in cash, out of the  
\$12,000. This was a  
travagant purchase.

Governor Clark of  
council at Prairie du

est, of which the object was, by a defilement of boundaries, to put a stop wars which for years these tribes had against each other. In 1826 he met the was in council at Fond du Lac, at the extremity of Lake Superior. In 1827,

d in a treaty at Green Bay, he was  
upon to assist by his presence in sup-  
the hostilities which had broken out  
the Winnebagoes and the miners at  
iver, near Galena. Ascending the Fox  
ascending the Wisconsin and the Missis-  
St. Louis, and returning to Green Bay  
Illinois river and Lake Michigan, he  
d, in the course of 2 months, nearly 4,000  
mostly in birch bark canoes, as yet the  
means of conveyance on those waters.  
he made 2 treaties, one at Green Bay,  
or at St. Joseph's, by which many mil-  
acres were ceded to the United States.  
his resignation of the office of governor  
gan, in July, 1831, he had concluded 19  
with the Indians, by which cessions had  
quired in Ohio, Indiana, Illinois, Michi-  
Wisconsin, to an amount equal to near-  
ite a fourth part of the entire area of  
ates. Meanwhile, he embodied his ex-  
and intimate knowledge of the Indians  
ir affairs, the fruits of his long inter-  
ith them, and of a diligent study of what  
d been printed on the subject, in two  
published in the "North American Re-  
one in 1828, in the 50th number of that  
al, and the other in the 55th number.  
rticles attracted much attention, and  
ted largely to make their author

The second article contained a full re-  
the relations between the Indians and  
tish and American governments, and  
the recent Indian disturbances to Brit-  
igation. These articles, with a dis-  
which Mr. Cass delivered in 1829 before  
ly formed historical society of Michigan,  
for him a literary reputation, and oc-  
applications to him for anniversary ad-  
and contributions to periodicals, with  
e frequently complied.—When President

reconstructed his cabinet in August, Mr. Cass was appointed secretary of war. His policy of the removal of the Indians, especially the southern tribes, to districts west of the Mississippi, had been warmly espoused by Gen.

The defence of this policy, which had much criticism and a warm opponent, was ably entered upon by Secretary his first annual report. Soon after, he had to break a lance with the supreme the United States, upon the question of t of the state governments to extend te laws over the Indian tribes within rritorial limits. In the case of the es, the supreme court had decided that e of Georgia had no such right. This

was criticized and controverted by Cass in an elaborate disquisition, and in the Washington "Globe," then the

organ of the government. The state courts of Georgia, taking a similar view of state rights, did not hesitate to imprison and hang in defiance of the supreme court of the United States. The removal policy, which was vigorously pushed, greatly strengthened the administration of Gen. Jackson in the South, but it was attended with an unlooked-for consequence, and met with an unexpected obstacle in the Florida war, the first 2 years of which fell within the period of Mr. Cass's administration of the war department.—In 1836 Mr. Cass exchanged his post of secretary of war for that of ambassador to the French court. Having got through the press of business which grew out of the recent interruption of diplomatic intercourse, occasioned by the indemnity dispute, and having settled the last remnant of that controversy by obtaining the interest on the indemnity withheld when the principal was paid, Mr. Cass in 1837 embarked at Marseilles for a voyage in the frigate *Constitution* to Egypt by way of Constantinople. The vessel followed the coast, and stopped at the principal ports, whence excursions were occasionally made into the interior. Mr. Cass had thus an opportunity to see not only Constantinople, Alexandria, and Cairo, but Genoa, Leghorn, Florence, Rome, Palermo, Malta, Athens, Corinth, and Jerusalem. The *Ægean* sea, of which he visited several of the islands, reminded him of the vast fresh-water seas of America, on which he had so often sailed. In the river Nile he found a strong resemblance to the swift and turbid Missouri. During his subsequent residence at Paris, Mr. Cass made frequent journeys in France, and also visited England. He was on excellent terms with Louis Philippe, of whose character he gave a very friendly and favorable account in his "King, Court, and Government of France," published in 1840, originally as an article in the "Democratic Review." By far the most remarkable incident of his diplomatic career occurred just at its close, in his attack on the quintuple treaty for the suppression of the slave trade. Great Britain, subsequently to the year 1815, had taken that suppression vigorously in hand, but had soon found that the right of searching suspected vessels was a very necessary means toward accomplishing its object. It was decided, however, by the British admiralty courts that search was a purely belligerent right which did not exist in time of peace. Great Britain then sought to obtain this right by treaties, stipulating its mutual concession. Such a treaty was made with the United States in 1824, granting a mutual right of search "on the coast of Africa, the West India, and America," of vessels suspected to be slavers. The senate of the United States, in ratifying this treaty, struck out the word "America," which caused its rejection by the British government, in the hope of subsequently obtaining a larger concession. This hope, however, was disappointed. There was a disagreeable association in the American mind between search and impress-

ment, and the American government from this time forward steadily refused even what the rejected treaty had conceded. Meanwhile, Great Britain established this right of mutual search of suspected slavers by treaties with Spain, Portugal, France, and other states, and in further prosecution of the same policy, and with a view to incorporating this usage into the international code of Europe, and ultimately of Christendom, obtained the signature at London, Dec. 20, 1841, of a treaty by which Great Britain, France, Russia, Austria, and Prussia mutually conceded this right under certain restrictions, and between certain latitudes. No sooner had the signing of this treaty, known as the quintuple treaty, become public, than Mr. Cass not only filed a protest against it in the French office of foreign affairs, but printed a pamphlet in hopes to prevent its approval by the French chambers. This pamphlet accused Great Britain of aiming, under guise of suppressing the slave trade, at a lordship of the seas, revived the impressment controversy, and attacked with much keenness the doctrine lately set up by Lords Palmerston and Aberdeen, in their correspondence with the American minister at London, that although, except by express stipulation, there was no right of search for the suppression of the slave trade, there was a right to visit suspected vessels for the purpose of verifying the flag and testing the right to bear it. This claim had been made the subject of animadversion in President Tyler's annual message of Dec. 1841, and it was the position then taken by the president upon which Mr. Cass mainly rested his protest against the treaty, as an attempt to interpolate a new doctrine into maritime law. At the close of this protest, which bore date Feb. 13, 1842, Mr. Cass stated that it was made without instructions from his government, with which there was no time to communicate, and that if not sustained in the position he had taken he should resign. In communicating his proceedings to his own government, he pressed the necessity of instant preparations for war. The feeling of the French public and the French chambers, easily excited at that time to hostility to Great Britain, was such that Louis Philippe did not venture to ratify the treaty, which thus fell to the ground. The course adopted by Mr. Cass, though it brought great obloquy upon him from various quarters, was approved by the president; but in the Ashburton treaty, negotiated shortly after, Mr. Cass found occasion for throwing up his mission. The agreement of the United States in that treaty to maintain a squadron on the coast of Africa, to coöperate with the British in the suppression of the slave trade, without at the same time requiring from the British a renunciation of the doctrine of the right of visit, was regarded by Mr. Cass as substantially a disavowal of his protest and pamphlet, and as placing him in an awkward position with the French government, by no means well pleased with his in-

terference to defeat the quintuple treaty, accordingly resigned his embassy, and returned home, where he arrived at 1 o'clock on the 1st of March, 1842. His criticisms on the treaty were contained in his letter of resignation, which caused a sharp controversy between him and Mr. Webster, then secretary of state, and Mr. Calhoun, then senator from South Carolina, and Mr. Van Buren, then governor of New York, and Mr. Polk, then governor of Tennessee, and Mr. Cass had been mentioned as a democratic candidate for the presidency, and he soon had to answer as to his opinions on the subject. But the negotiations opened not long after, between President Tyler and Mr. Calhoun, for the annexation of Texas, introduced a new element into politics, on which the presidential election finally turned. Mr. Clay, the champion of the whigs, and Mr. Van Buren, for whom a majority of the delegates elected to the democratic nominating convention were to vote, both took grounds against the annexation. That policy, however, exceedingly popular at the South, and between Mr. Calhoun and President Tyler, both of whom had hopes of a democratic nomination, R. M. Johnson, then governor of Tennessee, came out as its advocate. Mr. Cass gave in his adhesion, in a letter to Mr. Van Buren, a few days before the meeting of the convention, advocating annexation, and declaring his conviction that a majority of the delegates would be in favor of it. The convention met at Baltimore, May 27, 1844. The opposition to Mr. Van Buren succeeded in carrying over the rule of the convention of 1836, requiring a two-thirds majority. On the 1st ballot Mr. Van Buren had a majority, but lacked some 20 of the two-thirds. Mr. Cass had the honor of a though very much smaller, vote. On the 2d ballot, Mr. Cass gained, and on the 3d ballot received 24 votes more than Mr. Van Buren, but still short of a majority. On the 4th ballot Mr. Van Buren was withdrawn, and his friends, who had determined to give their votes for Mr. Polk, to the exclusion of Mr. Cass's name was also withdrawn. On the 5th ballot, being read in which he authorized the president, in case it did not appear, and united exertion would be made in his favor. Mr. Polk, who had been mentioned by the public for any high office, and whose name had been introduced into the canvass till the 8th of June, he received some 80 votes, was at the 6th ballot unanimously nominated. In the campaign that followed, Mr. Polk, partly stumping the states of Kentucky and Ohio, on behalf of Mr. Polk, and Mr. Polk's election, he was elected U. S. senator from the state of Tennessee, and into the Union in 1845, increasing in population. Dec. 1845, he soon made his name on the Oregon question, and his reputation with Great Britain.

enance at all hazards of our claims as far 54° 40', to which it was contended that the people and the party had been pledged by the Baltimore platform, not less than to the annexation of Texas. In the course of one of his speeches on this subject, he took occasion to retort upon Lord Brougham, who, in consequence of his interference with the quintuple treaty and his pamphlet against it, had stigmatized him as "the impersonation of mob hostility to Great Britain." The Oregon dispute was soon settled by a treaty made and ratified by the help of the whigs, in spite of opposition of Mr. Cass, and of a considerable section of the democratic party; and the government was thus left free to engage in the war against Mexico. This war led to the introduction into congress by Mr. Wilmot, a democratic representative from Pennsylvania, of a proviso, famous as the Wilmot proviso, that from all the territory acquired by the United States with Mexico slavery should be excluded. The proviso, at its first introduction near the close of the session of 1846, seemed to have the most unanimous support of the northern section of the democratic party. No vote was taken upon it at that session in the senate; but Mr. Cass afterward admitted that, had the opportunity occurred, he should have voted for it. When this question came up again in March, 1847, he advocated its postponement till after the close of the war. As the war approached its conclusion, his famous Nicholson letter made its appearance. This letter, dated Dec. 24, 1847, proposed to keep the question of slavery or its prohibition in the territory to be acquired from Mexico out of congress, by setting up for the legislatures of the territories an exclusive right of determining their own domestic institutions, equivalent to that possessed by the states. Mr. Cass declared himself in this letter decidedly opposed to the Wilmot proviso, as standing in the way of the acquisition of territory, and as unnecessary, since, from the character and climate of the country about to be acquired from Mexico, slavery could hardly go on. He did not deny his change of opinion on this subject, but justified it by the change simultaneously going on in the public mind. At the democratic nominating convention which was held at Baltimore May 22, 1848, that change was manifest. In that body the Wilmot proviso had few or no friends, except one branch of a double delegation from New York. These New York Wilmot proviso men, refusing to divide the vote of that state with the rival delegation, as the convention had proposed, presently retired from that body, leaving New York without a vote. The principal candidates were Mr. Cass, Mr. Buchanan, and Mr. Winthrop, all anti-Wilmot proviso men. On the 1st ballot Mr. Cass took the lead, and on the 4th ballot he received the requisite two-thirds of the votes cast, and was declared the candidate. He found, however, a formidable opponent in Gen. Taylor, nominated by the

whigs on the strength of his military reputation acquired in the Mexican war; and he was still further weakened by the determination of the New York seceders from the convention, the special friends of Mr. Van Buren, not to support him—a resolution in which they were sustained by the acceptance on the part of Mr. Van Buren of a Wilmot proviso, or as it was called a freesoil nomination. The division thus made in the democratic ranks secured to Gen. Taylor the state of New York, and his election to the presidency by a majority of 36 electoral votes.—Mr. Cass, on being nominated for the presidency, had resigned his seat in the senate, but subsequently to his defeat was again elected in June, 1849, for the remainder of the term he had resigned. At the next session of congress, the Wilmot proviso being still agitated, and he himself being under instructions from the Michigan legislature to vote for it, he entered into an elaborate defence of the doctrine of his Nicholson letter, now fully taking the additional ground that the Wilmot proviso would be unconstitutional, congress having no right to legislate upon a subject over which the constitution gave that body no control. He professed himself a believer in the doctrine of instructions "when fairly exercised and under proper circumstances," and promised to resign rather than disobey. He had, however, as he was well aware, sufficient influence with the Michigan legislature to procure the recall of the instructions. He was a member of Mr. Clay's compromise committee of 1850, and supported all the measures which emanated from it, including the new fugitive slave bill. But he did not vote for that bill, excusing himself on the ground that it made no provision for giving the alleged fugitive, after he was carried back, a trial by jury to ascertain if he were really a slave. Such a provision Mr. Cass insisted would have rendered the bill much less objectionable to the free states. Being reelected a senator from Michigan for a second term of six years from the 4th of March, 1851, he still continued a prominent democratic candidate for the presidency. But in the convention which met at Baltimore in May, 1852, beside Mr. Buchanan and Mr. Marcy, he encountered another formidable competitor in the person of Mr. Douglas, who stood in this convention in much the same relation to Mr. Cass in which Mr. Cass had stood in that of 1844 to Mr. Van Buren. The contest was long, but after a struggle of 5 days and 49 ballots, Mr. Cass found himself again passed over, and Franklin Pierce selected by a compromise among the conflicting interests as the candidate of the democratic party. The slavery controversy, which experienced a temporary lull after the passage of the compromise acts, revived with new vehemence upon the introduction into the senate by Mr. Douglas, at the commencement of 1854, of the Kansas-Nebraska bill, including a proposed repeal of the Missouri compromise, or rather of that part of it excluding slavery from that portion of the

Louisiana cession north and west of Missouri. Mr. Cass declared himself opposed to this new agitation. He was aware, he told the senate, that it had been reported that he himself had intended to bring in a bill respecting the Missouri compromise, but this he declared to be a total mistake. The bill, however, having been modified by introducing into it the doctrine of the Nicholson letter, in a provision leaving to the inhabitants of the territories the power to regulate their own institutions in their own way, subject only to the constitution of the United States, Mr. Cass voted for it, and on the night of its passage he took occasion to congratulate the senate on the triumph of "squatter sovereignty." The passage of this bill led forthwith to the organization of a new party based on opposition to the extension of slavery, and which, under the name of the republican party, soon became predominant in most of the northern states. It triumphed even in Michigan, where Mr. Cass was unable to secure a reelection as senator. He even received from the legislature a new set of instructions as to his votes on the Kansas question, no less contrary to his own views than those on the subject of the Wilmot proviso of which he had formerly procured the recall. These instructions he did not obey, nor did he resign his seat. He took the ground that in order to be binding, instructions must come not merely from the legislature, but from that party in it to which the senator sought to be instructed was indebted for his seat; and as that was not the case with these instructions, he declined to pay any attention to them.—In the convention which met at Cincinnati in May, 1856, to nominate a democratic candidate for the presidency, Mr. Cass was no longer a candidate, beyond receiving a few scattering votes; but in the nomination by that body of Mr. Buchanan he heartily concurred, and upon Mr. Buchanan's entering upon office in March, 1857, received from him the appointment of secretary of state. In this capacity he has been enabled to achieve a very gratifying triumph, in obtaining from the British ministry the recognition as correct of his denial, so warmly urged in his pamphlet on the quintuple treaty, of the existence in time of peace of any marine right of visit; he conceding, however, that in cases of grave suspicion of a false assumption of national character, and where no injury results from the visit and search, no serious ground would exist for national reclamation.—In the enjoyment of excellent health, Mr. Cass still retains, notwithstanding his advanced age, a remarkable capacity for labor. Possessing naturally a very robust constitution, he has confirmed his health by strict temperance, himself practising that total abstinence from intoxicating liquors which, as governor of Michigan, he urged upon the Indians, and as secretary of war, sought to introduce into the army. "His habits are simple, his manners and disposition democratic; his style of living plain but substantial; and his residence not ostentatious

but elegant. Averse to idleness, he is merry with his companions, and in his friendship. He is remarkable for his liberality to young persons, and surrenders at his own table, he can be as happy as the gayest of them. In study and pleased with his own reflections, he is not a recluse, but on all occasions his admirers, friends, and fellow-welcome to his large and hospitable. To a well selected library he makes additions from the numerous publications of the day. He delights to pass an hour or so in the perusal of romances such as those of Cooper, Irving, or the like." See "Times of Lewis Cass," by W. L. G. New York, 1856. The same friendly biographer notes as a marked characteristic "having always evinced an aversion to anything that savored of British."

CASSANDER, king of Macedonia, Antipater, born about 354 B. C. He disputed the sovereignty of Polysperchon, whom Antipater made regent at his death in 319. All with Ptolemy and Antigonus, he Athens; captured Olympia, the Alexander the Great, and put her to death. He joined, in 315, the coalition against the growing power of Antigonus. In 311, the rightful heir to the throne, Perseus, and his mother Roxana; and title of king in 306, which was confirmed to him by the decisive battle of Ipsus.

CASSANDER, GEORGE, a Friesian, born in the island of Texel, in 1515, died Feb. 8, 1580, some time as professor of divinity at Ghent, and gained a high reputation by his various attainments. In 1561 he published a treatise, designed to reconcile the Protestant theologians, which was rejected by Calvin, but favorably received by Ferdinand and other German princes, encouraging him to a conciliatory task. He now published a famous work entitled *Consensus Fidei inter Papistas et Protestantos* in which he reviews the controversy of the Augsburg confession. He was attached to the Roman Catholic Church; was accused of taking too favorable views of the points brought forward by the Protestants, and several of his writings were condemned by the council of Trent. His collection was published in Paris in 1616.

CASSANDRA, called also ALEXANDRA, a Trojan princess, daughter of Priam and Hecuba. Apollo, enamored of her, permitted her to ask of him whatever she desired, as a reward for her complaisance. She begged for the gift of prophecy; but when the god had bestowed it upon her, she refused to keep her promise to him. Thereupon Apollo, unable to withdraw

her the prophetic art, ordained that her edictions should never be believed. In vain she foretold that the abduction of Helen would be the ruin of Troy—counselled the making of the wooden horse with the Atridæ—announced to Priam, and the Trojan people, the fate which awaited them—and opposed the reception of the wooden horse. On the night of the capture of Troy, she took refuge in the temple of Minerva, but was torn away from the statue of the goddess by Ajax, son of Oileus. She fell at last as a slave to Agamemnon, who carried her to Greece; and, after fruitlessly advising the prince of the fate which was reserved for her, she perished with him in the massacre ordered by Clytemnestra. She is an important personage in Greek poetry, and is the heroine of a poem by Lycophron, celebrated for its obscurity.

CASSANO, a picturesque town of Naples, in the province of Calabria Citra, in the district of 10 m. E. of Castrovillari; pop. about 6,000, rising many Arnauts. It is built in the deep recess of a steep mountain, round an isolated rock, on which are the ruins of an ancient castle. It is the see of a bishop, contains a cathedral, 4 convents, an episcopal seminary, and hot sulphurous springs, and plaster and stone quarries are in the vicinity. The inhabitants are principally employed in the manufacture of macaroni, leather, table linens, and fabrics of cotton and silk. Cassano is supposed to stand on the site of the ancient Cosa; according to some other authorities, however, the neighbouring village of Civita (an Albanian colony) occupies the real site of the ancient town. Cassano town in the province of Principato Ultra, 8 S. W. of St. Angelo, has a fine church, a hospital, 2 charitable institutions, and a paper manufactory; pop. about 4,600.—There is another Cassano in the province of Bari, and there are several places of the same name in Lombardy. CASSANO SOPRA ADDA, a town of Lombardy, in the government and 16 m. N. E. of Milan, noted for its numerous silk factories. The town occupies an important military position on the river Adda. A battle was fought here, Sept.

1259, which resulted in the defeat and capture of the tyrant Ezzelino. On Aug. 16, 1795, a victory was gained here by the French under Vendôme, over the imperial troops under Prince Eugene; and on April 25, 1799, the French, under Moreau, were defeated here by the Russians and Austrians, under Suwaroff.

CASSATION, COURT OF, the highest court of appeal in France, was established by the first constitutional assembly, Nov. 27, 1790, under the name of *tribunal de cassation*, with a view of putting an end to the confusion that had so long prevailed in the judiciary system of the country, and of imparting to the whole jurisdiction a spirit of unity, without endangering the independence of the inferior courts. In 1804 the name of *cour de cassation* was given to the court, which it still retains. The functions of the court are not to go into the facts, but

simply to revise the proceedings of the inferior courts, and any decision taken by the court of cassation is considered final and binding. It is composed of a president, 8 vice-presidents (*présidents de chambre*), 45 counsellors, an attorney-general (*procureur général*), 6 assistant attorney-generals (*avocats généraux*), a chief clerk (*greffier en chef*), and only 60 advocates are permitted to plead before the court. The counsellors are elected for life, and in the case of one dying, the emperor proposes three new candidates, of whom the senate chooses one. The president, the vice-presidents, the attorney-general, and the assistant attorney-general, are appointed by the emperor. The court is divided into 8 chambers, one for appeals in civil and one in criminal cases, and the chamber of requests, a sort of preliminary tribunal, which decides on the *locus standi* and admissibility of the appeal.—A court of cassation and revision was established in Berlin in 1819, for the Rhenish provinces of Prussia; the Düsseldorf court of appeal and 6 district courts are under its jurisdiction.

CASSAVA, the meal, and bread made from it, obtained from the roots of several species of the genus *manihot* (from the Indian *manioc*)—plants of the family of the *euphorbiaceæ*, which grow in the West Indies, South America, and Africa. Three species are described, but under different names by different botanists. The genus, formerly included in *jatropha* of Linnaeus, was separated by Kunth, and called *jani-pha*; and the common species was designated as *J. manihot*, of which two varieties, the sweet and bitter, are distinguished. But later authorities designate the genus as *manihot*, and the common species as *M. utilisima*; another species as *M. aipi*, and a third as *M. jani-pha*. The first is the bitter cassava, indigenous to Brazil, and cultivated in other parts of South America. It is a shrub that grows 6 or 8 feet high, and has a large tuberous root, which sometimes weighs 80 pounds. This root contains a large proportion of starch, which is associated with a poisonous milky juice, containing hydrocyanic acid and a bitter acrid principle. The other two species do not possess this poisonous juice. All are used alike for the preparation of the meal. The root is well washed, then scraped or grated to a pulp, and this, when of the poisonous kind, is thoroughly pressed in order to remove the juice; but even if some of this is left in the meal, it escapes by its volatility in the process of baking or drying the cakes upon a hot iron plate. Afterward dried in the sun, the cassava is kept as food, to be mixed with water and baked like flour in large thin cakes. These are a coarse, cheap kind of bread, much used by the negroes and poorer whites, in which the ligneous fibre is plainly visible. Its nourishing qualities consist in the starch of which it is principally composed. The expressed juice also furnishes by deposition a very delicate and nearly pure starch, when left to stand for some time. Well

ODORUS, MAGNUS AURELIUS, a Ro- esman under the Ostrogothic mon- n at Scylacium, in the Bruttium, A. D. of death unknown. He was of an an- wealthy Roman family. In his youth uished himself by his talents. Odoacer, ne Heruli, the 1st barbarian king of ed the young Roman to the high office *verum privatarum*, and afterward to *nes sacrarum largitionum*, which gave ommand of the treasury of the king- en Theodoric, king of the Ostrogoths, and supplanted Odoacer, he used his among the Bruttians and the Sicilians their peaceful submission to the Os- monarch. Theodoric gladly took him ervice, and for many years, and under les, he was prime minister of the bar- gdom of Italy. When Theodoric in e began to persecute the leading Lat- service, Cassiodorus prudently re- situation and dignities, and retired tes. After the death of Theodoric called to power, served with distinc- fidelity Amalasontha, Athalaric, The- id Vitiges. Upon the temporary tri- he emperors of the East, being now 70 ge, he retired again to the monastery which he had founded in Calabria. In it he passed the remainder of his days, re prolonged until the ex-minister was entury old. His career as a historian of letters began when his career as an ended. The monastery of Vi- emorable in the history of the human

mind. Cassiodorus taught his monks to labor in the fields as husbandmen, and to devote themselves to the copying of ancient manu- scripts, then perishing rapidly under the effects of barbarian ascendancy and Roman neglect. This monastery was taken as a model for others founded in all parts of Christian Eu- rope. His arrangement of the branches of a liberal education into grammar, rhetoric, and dialectics (the trivium), and arithmetic, geom- etry, astronomy, and music (the quadrivium), was accepted throughout the middle ages, and long after, as the only true programme of a lib- eral education. His writings on education form a considerable part of his literary remains. His history of the Goths in 12 books has not sur- vived, but the epitome of the same by Jornan- des is extant, and is an invaluable authority. Equally important in a critical point of view are his state papers in 12 books, which fortunately have survived. These documents are our chief authority upon the internal condition and gov- ernment of Italy during the period of Ostro- gothic rule. The style is very florid and af- fected, the language very corrupt. Tiraboschi characterizes them as *barbara elegans*. He also wrote a universal history down to A. D. 519, and an ecclesiastical history from the era of Constantine down to the time of Theodosius the younger. These 2 works enjoyed great consideration during the middle ages, but since the revival of learning have fallen into oblivion. The 1st edition of his works was published at Paris in 1584; the latest and best is that pub- lished by D. Garet at Rouen, 1679, and reprint- ed at Venice, 1729. We have 8 biographies of Cassiodorus, one in Latin, prefixed to Garet's edition of his works; another in French by St. Marthe, Paris, 1694; and a 8d in German by De Buât, in the 1st volume of the transactions of the royal academy of Munich.

CASSIOPEIA, a northern constellation, easily recognized by the form, a letter W, on the op- posite side of the pole from the Great Bear; named from the wife of Cepheus (king of Ethi- opia), and mother of Andromeda. (See Ovid's "Metamorphoses," V., and the "Phenomena" of Aratus, 187.) The constellation was distin- guished in 1572 by a brilliant temporary star which shone for 18 months and then disappeared. It was this phenomenon that led Tycho Brahe to study astronomy.

CASSIQUIARE, or CASSIQUIARI, a deep and rapid river of Venezuela. It forms the S. fork of the Orinoco, and connects that river with the Rio Negro. Where it leaves the Orinoco it is 100 yards broad, and at its junction with the Rio Negro, about 600. By means of the Cas- siquiare water communication is established for canoes from the interior of Brazil to Caracas, in Venezuela.

CASSIS, in conchology, the name of a genus of univalve shells, separated, by De Lamarck from the buccium of Linnæus. It includes the species known as "helmets." Fine specimens of this genus are obtained for the use of the cameo

artists, the different colored layers of which the shell is composed rendering it particularly well adapted for their use.

**CASSITERIDES**, or **TIN ISLANDS**, supposed from the quantity of tin which the Phœnicians, Carthaginians, and Romans derived from them, to be the modern Scilly islands, near the coast of Cornwall, England. Their position, too, as defined by Strabo, corresponds more nearly with the Scilly group than with any other. Situated almost within the English channel, they have been very dangerous to modern navigation, and are become not less celebrated for the shipwrecks which they have caused than for their mines of tin. The Phœnicians who first discovered these islands were so jealous of the commerce which was supplied by them that their pilots first landed upon the neighboring coasts, and approached the mines only by stealth, to elude any ships which might be following and observing. The Romans sent here their criminals to work and be useful. The ancient inhabitants of these islands were accustomed to dress in black, to lead a wandering life, supplying all their wants by fish, milk, and the wool of their flocks, and satisfied in receiving salt and little brass utensils in return for their lead. The group consists of 45 islands, several of which are only naked rocks.

**CASSIUS**. I. **LOVENTIUS CASSIUS**, the leader of the conspiracy against Cæsar, died in 43 B. C. In 58 he was quaestor in the campaign against the Parthians, and distinguished himself by military skill, particularly after the death of Crassus, in the defeat of Carrhm. Having collected the remains of the army, he defended Syria, and won in the two next years 3 victories over the Parthians. After his return to Rome he was tribune of the people, embraced the party of the senate at the outbreak of the civil war, and followed Pompey, whose fleet he then commanded, in his flight. After the defeat at Pharsalia (48 B. C.), he led the fleet to the Hellespont, but having fallen in with Cæsar, he surrendered. Cæsar pardoned him, made him prætor, and promised him the province of Syria. At the same time Cassius was engaged with Brutus in forming a conspiracy against the dictatorial rule and the life of his benefactor. Cæsar fell on the ides of March, 44 B. C., and the senate rewarded his murderers with provinces. Cassius received Syria, where he defeated his opponent Dolabella, plundered its cities to provide means for the war against Antony and Octavianus, and returned with Brutus to Macedonia. The ensuing battles of Philippi (42 B. C.) ended their lives with the hopes of the Roman republicans. In the first, Antony defeated the wing of Cassius, who, mistaking the cavalry of the victorious Brutus, hastening to his relief, for that of Octavianus, killed himself, as Plutarch says, with the dagger which wounded Cæsar. In the second, Brutus, who mourned him as the last of the Romans, followed his example. II. **CASSIUS**, commonly called **Parmensis**,

from his birthplace, the city of Parma. He was a Latin poet of some merit. After the murder of Cæsar he adhered to the extreme republican party of Brutus and his associates, Cassius, and fought on their side until their defeat at Philippi; he then retired to Athens, where he was put to death by Verres, or Verrus, an officer of Augustus, who was sent there for that purpose by the triumvir. He is not to be confounded with Cassius of Etruria, who is ridiculed by Horace in his *Sermones* for his hasty and poverty of composition, but is believed to be the person alluded to by Shakespeare as torn to pieces in the streets of Rome by the mob immediately on the celebration of Cæsar's funeral rites, and the raising of the pyre by Marc Antony. III. **LOCIUS CASSIUS HEMUS**, the earliest Roman annalist, wrote about 30 B. C., and is often cited by Pliny and others. IV. **LOCIUS CASSIUS** a Roman lawyer and judge, famous for the severity of his decisions, whose all magistrates of extreme stringency came to be known as *Cassian judges*, as is mentioned by Cicero in his defence of Roscius. V. **TUS CASSIUS SEVERUS**, a Roman orator of considerable eloquence and great satirical power, sent by Augustus to the island of Sciriphus, where he died in extreme misery.

**CASSIUS**, **PURPLE** or, a pigment used in coloring porcelain and glass by fusing it with these substances. It is a precipitate obtained by adding proto-chloride of tin to a solution of chloride of gold. The purple powder thrown down is an obscure compound of sesquioxide of tin and oxide of gold. It contains of metallic gold 89.83 per cent. Its production is a test of the presence of protoxide of tin.

**CASSOCK**, a close garment resembling a long frock-coat, with a single upright collar worn under the surplice by clergymen of the Roman Catholic and Anglican churches. In the Roman church it varies in color, being black for priests, purple for bishops, scarlet for cardinals, and white for popes. In the Anglican church it is always black, and worn by all the 3 orders of the clergy.

**CASSOWARY** (*casuarus casu*, Latham), a bird of the ostrich family, the only species of the genus. The bill of the cassowary is long, compressed, and curved to the tip, the upper mandible overlapping the under. The wings consist of 5 strong rounded shafts without webs; the tail is not apparent; the tarsus long and robust, and covered with large scales; the toes are 3 in number, all directed forward; the inner toe is armed with a very long powerful claw. The head and base of the bill are surmounted by an elevated compressed cap, or bony helmet; the head and neck are devoid of feathers, the skin being of a blue and violet color, with 2 fleshy wattles in front. It is a heavy massive bird, about 5 feet high; the plumage is of a blackish color, the feathers being loose, and resembling delicate hairs; the feathers which take the place of the tail are pendant. The cassowary is a stupid, gluttonous

fruits, herbs, and occasionally on us; it is incapable of flight from the development of the wings, but it runs with rapidity, and defends itself by means of its powerful feet. It lives in pairs in the mountains of the Moluccas, of New Guinea, and in the Indian archipelago; in some parts it is domesticated. The female lays 8 spotted eggs, on the bare ground, on which she sits during the night for a month; the eggs are of a red color, mixed with the color of the cassowary, though it approaches more to the common birds in the shortness of its neck, and in the want of the stomach between the crop and the gizzard, besides its resemblance to the ostrich type, characterized by its large size, absence of wings, strength of its extremities, flattened breast bone, and the structure of the feathers.

**CASTALIA**, a fountain at the foot of Mount Parnassus, near the temple of Apollo, at Delphi, in Greece. It was, like the mountain, sacred to Apollo and the Muses, which were therefore called Castalides. In its sweet waters the Pythia used to bathe, before delivering the oracles of Apollo; it was regarded as a source of inspiration for poets, and had its name from Castalia, the daughter of Achelous, who, being pursued by her lover, threw herself into the fountain.

**CASTALIO, SÉBASTIEN**, a French theologian, born in Dauphiny in 1515, died in Basel, Switzerland, in 1563. His original name was Châteauneuf. Through the influence of Calvin he was professor of classical literature at Geneva. He quarrelled with the reformer, who caused his banishment in 1544, he repaired to Basel, where he taught the Greek language; but as he did not suffice to support his family, he was compelled to employ part of his time in agricultural labors. He made a translation of the Bible, the best edition of which is in folio, Basel 1573. He defended the right of free discussion in a collection of sermons compiled from various sources.

**CASTANETS**, a species of rattling instrument much used in Spain and southern France as a accompaniment to dancing. They derive their name from the chestnut wood out of which the Spanish made them, and are of considerable antiquity, having been introduced into Europe from the East. Two small pieces of wood, of hollow form, and fitting together like the halves of a nutshell, are fastened by a cord to each thumb, and the action of the fingers upon them produces the sharp click or rattling which imparts such a sprightly character to the national dances of southern Europe.

Castanets are sometimes employed in ballet

**CASTAÑOS, FRANCISCO XAVIER DE**, duke of Peñaranda, a Spanish general, born in Biscay in 1772, died in Madrid, Sept. 24, 1852. He studied the art of war in Prussia with his brother-in-law, the duke of Angoulême. On his return to Spain, Godoy, in place of peace, was the supreme ruler, and his opinions of this disgraceful favoritism

being loudly expressed, he was banished from Madrid. In 1808 he received the command of a division in Andalusia, and on July 19, he encountered the French army under Dupont, at Baylen. The battle commenced at 8 A. M., and lasted till noon, when the French were obliged to surrender; 18,000 were made prisoners of war; the Spaniards lost 1,000 men, the French 2,600. Castaños shortly afterward lost the battle of Tudela. In 1811 he was appointed to the Spanish army, coöperating with Lord Wellington, but, although he manfully supported the British in the battle of Vittoria, he was recalled from the army, and appointed to a civil office. After the restoration he was made captain-general of Catalonia in 1815, an appointment which he resigned, but again accepted in 1824. He was subsequently president of the council of Castile, and after Espartero's fall in 1843, became, for a time, the guardian of Queen Isabella.

**CASTBERG, PEDER ATKE**, founder of an asylum for deaf mutes at Copenhagen, born in Norway in 1789, died in 1828. After having studied medicine he travelled in Germany, France, and Italy, for the purpose of learning the most approved methods of teaching the deaf and dumb. He published several essays on the subject, and officiated first as professor, and afterward as director of the institution at Copenhagen.

**CASTE**. See **BRAHMA**, and **HINDOSTAN**.

**CASTEGGIO** (anc. *Ostidium*), a Sardinian town in the province of Voghera; pop. 2,800. It was taken by Hannibal during the 2d Punic war, and the battle of Montebello, in which the French, under Lannes, routed the Austrians, was fought in this vicinity, June 9, 1800. Near the town is a remarkable spring, called *Fontana d'Annibale*, or Hannibal's spring.

**CASTELLAMARE**, or **CASTEL-A-MARE**, a seaport town in the province of Naples, on the S. E. side of the gulf, 17 m. S. E. from the city of Naples, with which, since 1839, it has been connected by a railway; pop. about 18,000. It is finely situated on the lower slopes of a hill, along a sheltered beach, and commands an extensive view of the bay of Naples from Vesuvius to Misenum. It is defended by 2 forts, and contains a royal palace, a cathedral, 5 churches, several convents, manufactories of linen, silk, and cotton cloth, 12 thermal and mineral springs, and a dock-yard where the large ships of the Neapolitan navy are built. It has acquired celebrity also as a summer resort, in consequence of the salubrity of its air and the beauty of its environs. Castellamare is built upon the site of the ancient Stabia, which, having been destroyed by Sylla during the civil wars, was afterward occupied principally by villas and pleasure grounds. It was here that the elder Pliny, wishing to approach as near as possible to Vesuvius, during the eruption which overwhelmed Herculaneum and Pompeii, met his death, A. D. 79.

**CASTELLANE, EMMANUEL VICTOR**, ELIZABETH

**BONIFACE**, count, marshal of France, born in Paris, March 21, 1788. He entered the army as a private in 1804; had reached the rank of captain in 1810; distinguished himself in the Russian campaign, and was made colonel. On the fall of the empire, he joined the Bourbons; served as brigadier-general during the campaign in Spain; having supported an opposition candidate, he was dismissed in 1830; on the outbreak of the revolution he reentered the army and assisted in the siege of Antwerp; in 1837 he was made a peer, and served a few months in Africa. During the revolution of 1848, he officiated for some time as military commander at Rouen. Under the presidency of Louis Napoleon he was appointed to the military command of Bordeaux in 1849, and to that of Lyons in 1850. He was evidently in the secret of the projected *coup d'état* of Dec. 2, 1851, having beforehand taken measures to subdue by force, if needed, the republican population of Lyons. As a reward for his services he was made senator and eventually marshal of France.

**CASTELLI**, **IGNAZ FRIEDRICH**, a popular Viennese dramatist, born May 6, 1781. He was educated for the law, but following his inclination for the drama, he gained access to the orchestras of theatres as a player of the violin. His circumstances compelling him to look out for some means of support, he accepted various subordinate offices, but, using his leisure in composing patriotic songs for the Austrian army, he was brought into favorable notice. His songs having given umbrage to Napoleon, he fled to Hungary. In 1815 he accompanied Count Cavriani as secretary to Paris, and afterward he served in the same capacity with Baron Münch von Bellinghausen in Upper Italy. In 1840 he retired with a pension and the office of state librarian, and has since resided at his estate near Lilienfeld. The author of many poems, popular songs, and miscellaneous writings, he was at various times connected with the press of Vienna, but he is best known by his voluminous productions for the stage. Over 100 plays, partly adapted from the French, partly original, are attributed to him. In 1848, more than 100,000 copies of his political pamphlets, in favor of the revolution, found eager purchasers.

**CASTI**, **GIAMBATTISTA**, an Italian poet, born in 1721, died in Paris, Feb. 6, 1803. He officiated for some time as professor in the seminary of Montefiascone, and having afterward enlisted the sympathies of an Austrian nobleman, he was presented to Joseph II. and spent several years as unpaid attaché to foreign embassies, ingratiating himself into the favor of Catharine of Russia and of other potentates. At the death of Metastasio, he received the appointment of poet laureate at the court of Vienna, with a salary of \$1,500, but relinquished this office after the death of the emperor Joseph, and spent the last 20 years of his life in Paris. In early life he had written 18 poetical tales, and afterward

added 80:

in Paris in 1750, which are all but loose in moral and political poem, *Gli animali per* contrived to exhibit, under the blemishes of various political commenced the poem in Vienna, continued it in Florence, and completed where its original publication followed by several editions in German, and Spanish translated free and abridged English version other poems, he produced several operas, some of which were very successful.

**CASTIGLIONE**, one of the new settlements in the province of A established by the French government with a decree passed by assembly, Feb. 11, 1851. It is situated on shores of the sea near the town of K the plain of the Metidja, and on the Oherchell to Algiers. The plantation been established since that time in a flourishing condition, the soil being extremely and peculiarly well adapted for the of tobacco.

**CASTIGLIONE**, a village of Italy, di Roma, near the lake of Gabii. It is the site of the ancient city of Gabii in remains of antiquity. Old temple of Juno, a Grecian duct, are among its most interesting. The name of many places in Italy, beside the Calabrian village an earthquake in Oct. 1835.

**CASTIGLIONE**, **I. BALDASSARE**, statesman and author, born at Cas Mantua, Dec. 6, 1478, died at Toledo Feb. 2, 1529. His career of military service of the duke of better known as a diplomatist, in city he was intrusted by the with important missions to England, Louis XII. of France, and X. He became a favorite of the pontiff, and was regarded as one of the ornaments of his court. Clement VII sent him as nuncio to Madrid, but his arrival Rome was sacked by the under the constable Bourbon. It was possible for Castiglione to have foreseen this catastrophe, but the reproaches who insinuated that he had betrayed the interests of his country preyed upon him and hastened his end. He was universally loved, and the emperor, Charles V., in his death, exclaimed: "One of the treasures in Christendom is dead." He was a voluminous writer, but his *Il libro del Cortegiano* are models of composition. This *Il libro del Cortegiano* was first printed by Aldus in 1528, and a version was published in London in 1727. **II. CARLO OTTA**, philologist and antiquary, born in the close of the 18th century. He

relq Mai, he published an edition of a Gothic translation of St. Paul's Epistles. Mai had discovered among the papers of the Ambrosian library. Most of the variations which enrich the work, the portion of which extended through 20 volumes were written by Castiglione. III. **BENEDETTO**, called **IL GRECHETTO**, a painter and engraver, born in 1616, died in Mantua in 1670. He was a pupil of Paggi Ferrari, and, according to authorities, of Vandyke, and gained a high reputation as a historical, landscape, and portrait painter, and also as an engraver. His masterpieces were animal painting. Many of his works are in the museum at Florence, and in the Louvre at Paris; and some have found their way to Venice, Milan, Munich, and Dresden. An Italian artist and missionary, born in 1688, died in Pekin in 1768. He was thoroughly versed in the art of painting, but joining the Society of the Jesuits, Pekin was assigned as the theatre of his labors, and there he passed the greater part of his life, in favor with several Chinese emperors. He made his art an accompaniment to his religious labors, and the emperor K'ang-hsi erected several palaces from designs furnished by him. He is said to have successfully exerted his influence to protect Christians from persecution.

**CASTIGLIONE, LAKE OF**, in Tuscany, province of Grossetto, is about 10 m. long and 3 m. wide. It was formerly much larger, but has been reduced to its present size by the sea.

It receives the Bruna and other small streams, and communicates with the Mediterranean by a short channel. Its banks are unproductive and mostly depopulated. It has been proposed to communicate by a canal with the Ombrone, mingling with the waters of this river, supposed to make the lake more salubrious.

**CASTIGLIONE DELLE STIVIERE**, a town in the province of Mantua; pop. 1,200. It contains several churches and a castle. It is memorable for a victory of Napoleon over the imperial forces, Sept. 9, 1805, for the decisive victory gained here by Napoleon over the Austrians, Aug. 5, 1796, when Marshal Augereau acquired the title of Duke of Castiglione.

**CASTIGLIONE FIORENTINO**, in the province of Arezzo, Tuscany, is a town with a population of 1,200. It has a theological seminary, a bishop's palace, a Latin school, and orphan asylum, and is chiefly noted for the rearing of silkworms.

**CASTILLA** (Sp. *Castilla*), an ancient kingdom situated in the centre of the peninsula, divided into Old and New Castile.—OLD CASTILE is the more northerly of the two; area, 100,000 sq. m.; pop. in 1857, about 1,250,000. It is of an irregular shape, stretching from S. to N. It is bounded N. by the bay of Biscay, E. by Aragon and Navarre, S. and S. E. by New Castile, W. and S. W. by Leon. In the northern range of the Pyrénées runs

across the province. On the S. it is divided from New Castile by the Sierra de Guadarrama, the Somosierra, and a continuing chain, which, under different names, forms the entire S. and E. boundary. The rivers of Castile are the Duero in part of its course, its affluent the Tago in the centre, and part of the Ebro on the N. There are numerous minor streams: the Riaza, Piron, Cega, Eresma, Adaja, tributaries of the Duero; the Neva, the Oca, the Tiron, and the Oja, affluents of the Ebro. These rivers are blustering torrents after rains, but in summer many of them are mere water-courses. The climate is dry and hot in the summer, dry and cold in the winter. The plains are almost deserts, whose vegetation affords but a scanty pasturage, and disappears entirely under the summer sun. On the seacoast, and in the mountains, valleys, and hill-slopes, nature is much less sterile. Old Castile includes the provinces of Avila, Burgos, Logroño, Santander, Soria, and Segovia. The general occupation of the people in the interior is agriculture and grazing. In the towns some inferior manufactures are carried on. Corn and cattle are shipped from Santander.—NEW CASTILE contains an area of 80,872 sq. m.; pop. in 1857, about 1,800,000. It is much the larger division of the two, and from its contiguity to the Moorish kingdom, was the more important. It is bounded on the N., as we have seen, by the Somosierra, Sierra de Guadarrama, &c.; on the S. the lofty and rugged range of the Sierra Morena separates it from Andalusia. The province is intersected by the Sierra Molina range. Minerals abound, and the great quicksilver mine of Almaden is in the province. The Tago, and various tributaries, Tajuna, Henares, Jarama, Guadarrama and Alberche, Oedron and Algordar, with many small streams, flow through the province, in the plains N. of the Sierra Molina. The plains S. of the Molina are watered by the Guadiana and its affluents. The climate is the same as that of Old Castile. Large crops of wheat are raised, and the mountain slopes afford abundant pasturage. In the S. are the extensive plains of La Mancha. The inhabitants of New Castile are chiefly engaged in agricultural and pastoral pursuits. The vine is cultivated, and the fine wine of Val de Peñas comes from the district of that name. Olives and oil, saffron, honey, and hemp are produced in considerable quantities. Woollens, paper, linen, cotton, and silk are manufactured. The province contains Madrid, the capital of Spain, the city of Toledo, with Alcala, Arganda, Aranjuez, Almaden, Almagro, Ciudad Real, Cuenca, Guadalajara, Molina, Requena, Talavera, and Val de Peñas. New Castile is now divided into the provinces of Ciudad Real (including the greater part of La Mancha), Cuenca, Guadalajara, Madrid, and Toledo.

**CASTILLA, RAMON**, president of Peru, born at Tarapaca in 1798, served in the Spanish cavalry until 1821, when Gen. San Martin proclaimed Peruvian independence. Castilla, then

a lieutenant, joined the liberating army, in which he distinguished himself. He was elected president of Peru in 1845. At the expiration of his term of office, in 1851, he was succeeded by Gen. José Rufino Echéniqne, but usurped the power in 1855, and was, by a majority of 70,374 votes, reëlected to the presidency in Aug. 1858.

**CASTILLEJO, CRISTÓVAL**, a Spanish poet, born at Ciudad Rodrigo toward the close of the 15th century, died in Vienna, June 12, 1556 (according to other authorities in 1596), where his tomb has recently been discovered in the *Neukloster Kirche*. Attached from the age of 15 to Ferdinand, the younger brother of Charles V., and afterward emperor of Germany, he subsequently officiated as secretary to that prince. He was a zealous champion of the old Spanish poets, and a decided opponent of the new Italian school. His poetry generally reflects a genial and light-hearted nature. In his imitations of the old masters he exhibits a superior taste, and in his attack upon the imitators of the Italian poets, whom he called *Petrarquistas*, considerable spirit. One of his most fanciful and characteristic poems is entitled, "Transformation of a Drunkard into a Mosquito." His works were published in Antwerp in 1598, in Madrid in 1600, and were reprinted in Fernandez' "Collection of Spanish Poets," 1792.

**CASTILLO, JOSÉ MARIA DEL**, a South American patriot, originally a lawyer, was a member of the assembly of notables convened at Bogota by the Spanish viceroy on the breaking out of the Quito insurrection in 1809. Next he appears as a member of the constituent college which met at Bogota in 1811, and organized the state of Cundinamarca. In 1812 he represented the province of Tunja in the congress at Neyva; in 1813 was commissioned as acting governor of the province; and was appointed joint commissioner with Don J. F. Madrid to treat with Nariño. In 1816, when Bogota again fell into the hands of the Spaniards, he was sent prisoner to Omoa, in Guatemala. Subsequently he became secretary of the treasury in Colombia. In this position he continued till 1828, when, being elected president of the Ocaña convention, he was one of those who vacated their seats when the majority refused to confer new powers on Bolivar. For this service the dictator rewarded him (Aug. 1828) by the appointment of president of the council of ministers and of the council of state.

**CASTINE**, a town in Hancock co., Me., on the E. bank of the Penobscot, 34 m. below Bangor. It derives its name from the baron de Castine, a French nobleman, by whom it was settled in 1667, in company with a French colony, who afterward abandoned it in consequence of border wars with the Indians and English colonists. In 1760 it was settled by the English. The village is beautifully situated on a peninsula, enclosing a spacious harbor always accessible to vessels of the largest class. Its inhabitants are chiefly engaged in ship build-

ing and fisheries. It has 2 schools. Pop. in 1870, 1,450.

**CASTING**. The art of pouring molten metals is an art that has been practiced from the earliest periods, and has been improved by various improvements. A Midianite, in the time of Moses, xxxi. 24, used silver, gold, and lead, and it is probable that the same method was used 1,450 years before the time of the 28th chapter of Job, which have been written at a still earlier period. The casting of metal is made of silver and gold, and is the most difficult of the arts, and casting of the different metals properly includes all the arts used, as well as of the various processes employed. The art is too varied, and requires an explanation too many figures to admit here of more than a general line. It includes the construction of huge vessels, which require for each one several tons of metal to furnish the number of tons which fill its mould, or of the vessels which several are recorded as weighing 50 to 100 tons of brass, as the bell of Moscow, and the great bell of London, the latter of which is named. The construction of elaborate works of art in bronze, and of the most beautiful of the celebrated Benvenuto Cellini, of the finer parts of which no other are required to weigh as much as this same process; and so the expensive manufacture of reflecting telescopes, the construction of the brass work of the most extensive and greatly improved the stove foundries of the preservation in metal of the most insects and leaves of plants, the construction of the great plate mirrors and windows, which require first their appropriate moulds, the metals, as cupola and reverberatories, where large quantities are melted in the small brass furnaces, or in the larger furnaces. In the larger furnaces the metal is melted and exposed to the burning fuel; in the smaller vessels or pots are employed, in which the metal is placed, and thus kept while the burning matter, which the molten fluid is poured into, metal, sand, or other material. It is ordinarily the case for considerable dimensions, which must have the desired shape. These are made of metal, and being of considerable size they demand the use of large Flasks or boilers for the materials for

moving the heavy castings, or some large pots of melted metal from the mould, and stoves for drying the moulds that require this preparation. The list of the most essential workmen's tools, required for a

The cupola furnaces which are commonly so named from a cupola or dome sometimes placed over them to lead to the chimney. They generally consist of a cylinder of cast or boiler plate iron set upon a brickwork foundation, and filled with fire brick or refractory sand and their dimensions vary according as they are used for large or small operations. They are made to melt and hold about 12 tons and several such are placed in large yards side by side. One-tenth of this is more common. At the bottom is an opening sufficiently large for the extraction of iron, when this is required. It is closed by a hard-plate, which is provided with an opening for the flow of the metal, and this is closed with a lump of moistened clay after the metal has well started, and before the iron is allowed to melt. A number of smaller holes are put up the back for the introduction of air, the lowest being first used, and then the others in order, as the blast pipe is moved to the hole above, in consequence of the rise in the level of melted iron in the furnace. The furnace is driven by the fan blower. The furnace is filled at the top with charcoal, coke, or scrap iron, and after the contents are well fired, the pig iron, previously selected with special reference to the quality of casting, is thrown in with other charges of scrap iron. The pieces should not weigh more than 50 lbs. each; scrap iron is mixed with the pig iron, but care is always taken to so adjust the product that it shall be of the proper length or fluidity desired. A little flux is added to facilitate the fusion, and to remove the impurities of the iron. Castings made by second fusion in the cupola are not so commonly directly from the blast furnace, for the reason that qualities are obtained which are only obtained by mixing iron from different localities. It is a peculiar adaptation of Scotch pig to give length and fluidity that it is in demand along with other cheaper iron. The brittle Scotch pig made from bog ores, which may be so easily falling to break into several pieces, is in great demand for fine castings for its great running into the minutest parts of the mould, and retaining its faintest impressions. Castings, too, cannot always be depended upon any length of time to produce the quality of metal from the ores; and consequently, after preparing the moulds and letting them stand, it may prove altogether unsuitable for particular articles. Nor is the capacity of the cupola large enough to produce at a time so much iron as is often required for a

single article. Still, in many places they are advantageously employed to some extent, and good castings are very conveniently made by the first fusion.—When sufficient melted iron has collected in the cupola, the hole is opened at the bottom, and it is allowed to flow out into ladles which are carried by one man, or into larger ones, holding 800 or 400 lbs., carried by 3 to 5 men, or into a crane-ladle, in which 5 or 6 tons may be moved to the moulds. For heavy castings, the metal is often run, as from the blast furnace, in a channel in the sand, called a sow, leading to the moulds. These moulds in the case of the blast furnace may be only the pig-bed in which the depressions for the pigs branch off at right angles from the leading mother channel. The metal flowing through and filling these open channels presents at night particularly a most beautiful appearance; as it gushes out from the furnace in a stream of liquid fire, its intensely heated particles meeting the oxygen of the air fly upward in the most brilliant scintillations. But if, unfortunately, the stream comes in contact with sand too moist, violent action then takes place; as the moisture is suddenly converted into steam, and this is decomposed by the heated iron; the whole casting house is filled with the liquid particles thrown in every direction, and sparkling with fearful magnificence as they are consumed in the air. A slight accident sometimes gives rise to one of these catastrophes, which may be attended with the most serious consequences, to workmen and property. But flowing with its ordinary quietness, the metal is covered with wrinkling lines, which move rapidly over its surfaces and gradually become still as it solidifies.—The moulds, which are the next object of interest, may be made in the sand floor of the casting house, which has been filled in with the proper kind of sand for this purpose. This is light, fine, and loamy, and of a yellow color when new, but by the frequent addition of charcoal dust and other materials used in the moulding it gradually becomes dark-colored. It must also be too infusible to melt and adhere to the metal. In this, properly moistened with water, are imbedded the patterns of such articles as may be cast without a cover; and when the impression in the sand is perfectly made, the patterns are carefully taken out, and the imperfections of the sand-mould are skilfully smoothed and dressed over. Close moulds may be made of metal, and for repeating a great number of small castings, as of bullets or cannon balls, this is usually the case. They are commonly made in sand, either of the floor covered over with the upper half of a flask, or else in the sand included between the 4 sides of this flask or box, which has neither top nor bottom, except a loose board below and another above it. The flask is divided into 2 similar parts, which fit exactly one upon each other, and are fastened together by pins at the corners. The pattern is made in 2 parts, which accurately fit together to form

the whole figure; one part is imbedded in the sand of one portion of the flask, and the other so placed in the corresponding portion, that when the 2 are brought in contact and fastened, the exact figure of the object is left in the sand; just as when the 2 hemispheres of a bullet mould are brought together, the spherical cavity is made up between them. The little aperture through which the metal is introduced is made, as in the bullet mould, on the line joining the 2 parts, and is carefully impressed in the sand so that its sides shall bear the running of the metal. It is called the ingate, and serves also as a passage for the escape of the air in the mould. In large castings several of these are required; and in making use of them for pouring in the metal, it is necessary to pay particular attention to the escape of the air, that there is nothing to impede it; for if obstructed and the sand is too dense to allow of its passage through, it may cause the metal to be violently projected from the mould; or if bubbles of air remain shut in the metal, they render it porous and of uncertain strength. The object of the double flask is to admit of the moulding of all sides of a figure. Many objects of rather complicated shape may, by a little ingenuity, be so arranged as to be moulded in it without any projecting part having to pass under the sand, which would of course prevent the pattern being drawn out without breaking down the mould. If the shape is too complex to admit of this, the flask must consist of three pieces or more, so arranged as to admit of the moulding of all the parts without any portion being thus covered. Pieces of wood or brick, or sand properly moulded, are often used as cores to fill parts of the mould which in the casting are to be hollow. Over the face of the mould some light carbonaceous powder is sifted, which has the effect of giving a smooth face to the metal; in gold and silver casting the smoke of pitch or rosin is made to deposit a fine layer of soot for the same purpose. Red brick dust is often used as parting sand, to prevent the 2 parts of the mould from adhering together.—Patterns are the models of the object required, made usually of wood, and in the number of parts necessary for their perfect moulding. The wood should be thoroughly seasoned, and of the kinds least liable to change in form by warping or shrinking. White pine and mahogany, clear of all irregularities, are among the best. Their preparation is a distinct branch of the joiner's trade, calling for the exercise of no little ingenuity and skill. In consequence of the contraction of iron castings as they cool, the patterns should be correspondingly large. The allowance is made by the use of a contraction rule, in which the divisions are  $\frac{1}{8}$  of an inch in a foot, or  $\frac{1}{16}$ , longer than those they represent, this being the usual proportion of shrinkage. Brass shrinks 3 times as much as iron. The pattern designer is obliged always to have reference to the effect of unequal rates of cooling in the large and small parts of the castings, and

ingenious expedients are adopted to prevent injury that might arise from the contraction while the metal is setting. In the case of these the castings are made in two parts, the contraction while yet liquid being taken into the fact that the counterparts of the pattern should be proportioned to each other; and as the weight of the casting should be equal to the weight of the pattern. Wood patterns, of large size, are often built up of several pieces fitted together and glued. In the case of castings, as those for steam engines, which may be formed in a hollow core of iron or of wood, so constructed as to fit in the cavity, leaving the space for the metal to fill the wall of this cavity. In the case of a circular channel of the metal, and a large number of air-holes from this down into the metal, so that many air-holes are also formed in the metal. The channels coming from the top of the flow of metal in each one of the patterns by a workman who uses his shovels, the currents flow into the hollow core, soon filled. The hollow core, within to withstand the pressure of the metal, must, as soon as the commencement of cooling, be restrained by being laid upon the top. To accomplish this, the workman, by the highly heated cavity, by working a minute or so at a time, is soon removed. The metal is allowed to cool to a certain hardness; the former is chilled iron, is iron cast in a sand mould. The castings when removed are dressed by breaking off the crust of sand which covers them. In the ingates, and their counterparts, the crust of sand which covers them is removed by a ingenious method of ramming. This method is practised for some time, particularly in Baltimore. The pattern is made in a cast-iron tubular case, which is the outer mould. Being made to revolve on its axis, the fluid iron will fill the cavity and assumes the tubular shape corresponding to the quantity introduced.—It may be made in various methods employed for the delicate figures of plants, and also of large figures, or a leaf of a plant, or a cast figure, is made in a sand pattern. It is fixed by the pattern in a small box, and a wire is connected with the outside of the box, and is plastered over it, by

to the box and swinging this about.

Materials of the same nature are added in the same way till the box is filled. It is then dried, the wires are withdrawn, and the whole is baked, so as to reduce the object to a solid state.

These are then blown out, and the mould is ready to be filled. An improved process of moulding the object in wax, and having covered this with plaster of Paris, subject the whole to a heat sufficient to melt the wax and to be absorbed into the plaster. Casts of brass designed for printing the impressions of ferns and such objects are prepared by the ingenious process of Dr. Branson, of Sheffield, as follows: A clean sheet of percha, softened by boiling, is laid flat on a smooth plate of metal, and dusted over with fine bronze powder. On this is laid the frond or leaf, and it is then covered with another sheet of percha. When the gutta percha is cold, it is found to be impressed with a perfect copy of the object. From this a cast in brass is taken, which, when burnished, is ready for the printer. The prints thus obtained, if the ink be properly mixed to the right tint, are said to be indistinguishable from the plant itself.—

In making statues, a hole is dug in the sand, and a small furnace is sunk in the bottom. Over this furnace is placed an iron grate which supports the mould. This is formed of sand, ore, the wax, and the outer shell. The mass or core of clay and rough plaster represents the general contour of the form required.

It is strengthened by iron bars on the inside, and on the outside is covered with wax, the thickness of which corresponds with the thickness of the metal. This, however, is sometimes formed in separate pieces upon the core and brought to the core in sections. A series of tubular passages from the wax to the outside are left, to serve as ingates and for the escape of air. An outer coating is next laid of wax, formed of layers of different compounds. The first is of clay and old white crumbe powdered, and mixed with water to the consistency of paint. This is applied two or three times. For the 2d layer, the same is used, to which is added horse dung and water, and for the 3d the dung and earth.

When this shell is completed, the whole is lined with bands of iron. A moderate fire is made in the furnace, for the purpose of drying it, as well as for melting the wax, which runs out through pipes arranged for the purpose. These are immediately closed with sand. When this is done, the square pit is filled all around the mould with loose bricks, and a fire is increased in order that the mould may be thoroughly heated and dried. This being accomplished, the fire is extinguished, and the whole is left to cool, when the bricks are removed and their place filled with earth. The wax is now melted in a large furnace con-

structed by the side of the pit. A small tube is laid for conveying it into a large basin over the mould, into the bottom of which all the large branches of the spouts or casts are inserted, by which it is led into the various parts of the mould. These channels are closed with long iron rods, which are withdrawn only when the vessel is full enough of the metal for it to run into all of them at the same time. The whole of the furnace is then opened, and the mould is instantly filled. The casting is now complete, the mould and earth are removed, the core and the iron bars, except such as are required to strengthen the figure, are taken out through an aperture left in the brass for that purpose, which is afterward soldered, and the figure is ready for the finishing touches of the sculptor.—The value of the exports of castings of iron, manufactured in the United States, during the year ending June 30, 1857, was: to Canada, \$188,946; other British American possessions, \$75,172; British Australia, \$37,562; Cuba, \$12,868; England, \$8,981; British Guiana, \$5,286; Chili, \$5,167; other countries, \$11,488: total \$289,965.—See also BELL, CANNON, and FOUNDRY.

**CASTLE**, a fortification of the middle ages. The word is derived from the Latin *castellum*, although the castellum of the classic writers had little or nothing in common with the superb castellated edifices of Norman and Gothic architecture. The castellum of the Romans seems, at times, to have signified something of the nature of a system of detached forts or bastions, connected or unconnected with curtains, made sometimes of timber, sometimes of stone, and not unfrequently of a combination of the 2 materials; the stone work being compacted with heavy beams of timber, which were supposed to increase the strength of the edifice, as they were less liable to be brought down by the vibratory motion given to the walls by the repeated blows of the battering ram. At other times, the word castellum was used by the Romans to signify a fortified town, and that more frequently in the provinces, particularly in Gaul, than elsewhere; most of the French towns which have now the prefix of *château*, as Châteaudun, Château Thierry, and the like, being built on the site of ancient Roman *castella*; just as the English villages and towns having the suffix of *cester*, *caster*, or *chester*, as Doncaster, Gloucester, Colchester, are the *locum tenentes* of ancient encampments, *castra*. Lastly, castellum was often used by the Romans as a term for the large buildings of masonry used as fountains, or rather as the distributing reservoirs of their aqueducts, many of which, in fact, had very nearly the character of the simplest form of the small castle of the middle ages, some of which are still to be seen in Scotland, consisting merely of a square pile of masonry, having 4 flat curtains, with 4 projecting round or square towers flanking the curtains, 1 at each corner of the building, and rising considerably above the battlements of the main

pile, so as to command the platform, if carried by escalade. Roman towers are almost invariably made of brick, joined by cement or mortar, which with the lapse of time became harder than the brick it compacted, or than stone itself. When they used stone, it seems to have been in irregular works, of great extent, such as the *vallum* of Antoninus, or Severus, partaking of the nature of earthworks rather than of regular defences of masonry. The Saxon castles in general were of very inferior architecture and design; they had rarely the advantage of elevated position, or of commanding height in themselves. In fact, the Saxons were not, it would seem, at any time a castle-building race, nor did they affect lofty sites or eminences for their dwellings or defences. Their favorite localities for building purposes, so far as can be judged from the few old Saxon sites, such as Temple-Newsham and a few others in the north of England, and in the fen counties of Cambridge, Huntingdon, and Lincolnshire, were nearly the same as those affected by the monks after the conquest, many of whom were of the ancient Anglo-Saxon race—namely, low, rich meadow lands, suitable for the rearing and fattening of the flocks and herds, in which they took so much pride and pleasure, and in which so large a portion of their wealth consisted, lying by the margin of still sheets of water, containing carp and tench as fat as their own oxen, ever haunted by innumerable flocks of wild fowl, and over-shadowed by dark woodlands, as old as the days of the heptarchy, or perhaps as those of Cæsar. In such places, they would build their houses of strength (one could hardly call them castles), long, low, flat-roofed, rectangular buildings, with no attempt at ornament, and little at defence, beyond the smallness of the narrow round-topped windows and low-browed doorways, with here and there a low, stubborn, round tower at an angle, sometimes a moat drawn round the base of the building itself, and defended by an exterior palisade of timber, but without any system of flanking walls or defences, one defending and commanding the other, as was the case in the elaborate fortalices afterward erected everywhere throughout the land by the victorious Normans for the protection of their scanty numbers. It would seem, in fact, that neither during the Roman occupation of Britannia, nor afterward, while the Christianized and Latinized Cambro-Britons held it, nor yet after that, in the Anglo-Saxon times, while there were Anglo-Saxons in England, were there any places of strength in the kingdom. A single battle, won by a few charges of mail-clad horsemen, laid the whole kingdom prostrate at the feet of William the Norman, who portioned out the realm among his landless followers. Everywhere, instantly after the subjugation of the land, on every estate arose the tall and castellated dwellings in which,—from that day downward until the conclusion of the wars

of the Roses and the accession of the Tudors, when a new style of architecture, indicating a milder state of society and a cessation of domestic warfare, succeeded the old castellated type,—resided with their families, secure amid the din of war, the landed aristocracy and nobles of the land. Of every variety of size, from the small single keep, or tower, perched on some bold summit, to the vast baronial castles, such as those of Framlingham, or Ely, or Kenilworth, or Leicester, covering acres of ground within the precincts of their embattled walls and deep girdling moats, they had all similar forms, one common system of defence, whether on elevated ground or amid low scenery; and, unless captured by surprise, in a sudden onslaught, or betrayed by the flight of some one within the walls, could all, for many days, resist a feudal army; the best artillery of which, consisting only of catapults and machinery for casting stones, could effect nothing against stone walls of 10 or 12 feet thickness, and 100 feet or more in height, save every shot hole, crenelle and bartizan of which, arrows and cross-bow bolts fell like hail on the exposed persons of the assailants; while it mattered little to the defenders of the castle whether or no, in the absence of artillery adequate to reduce it, the edifice might or might not be commanded by eminences of superior height, provided only that they were not within near arrow shot.—The system of defence was a series of curtains of great strength and height, forming the circuit of the defences, with large square flanking towers at short intervals, serving as bastions to enfilade the curtains, and close at their base a wide, deep moat only to be crossed by means of a drawbridge, and even to that drawbridge defended, on the outer side, by what was called a barbican, serving as what we should now call a bridge head, which was in fact neither more nor less than a small castle of inferior height to the interior fortress, open to its shot on the inner side toward the moat, so as to be untenable against its garrison, yet strong with curtains, towers, flankers, and sometimes, again, with a narrower exterior fosse and esplanade, and an exterior palisade of wood, called the barrier, in the attack of which and their defence were often performed some of the most desperate and glorious feats of arms recorded by the chroniclers and minstrels of the middle ages. In many of the larger and more powerful feudal fortresses, such as that of Framlingham in Suffolk, of Flinches Tours and Loches in France, and many others in England, France, and the Low Countries, within the exterior precincts and moat, there were a 2d and 3d wet ditch, a 2d and 3d wall, each loftier than that without, and commanding it from the base to the summit; and all these arranged in such a way that the assailants, having mastered the 1st gate and entered the 1st precinct, would necessarily be compelled to make a flank movement round half the circumference of the place, shut up be-

high inner wall and an impassable under shot from the 2d wall, before the 2d bridge and gateway. Add to it, the 2d wall gained, a similar task before carrying the 3d; and when the 3d should be all forced, one by one, the whole, in the shape of the keep or a pile of masonry almost solid, and of almost impregnable, consisting principally a huge square tower of 200 feet or height, with a flanking turret at each not a window larger than a shot hole and of the longest ladder, and but one entrance on the 3d floor above the ground, accessible only by an exterior stair of stone, "so where one but goes abreast," exposed long-bow shafts, and cross-bow bolts, and of melted pitch and scalding oil from elements and bartizans, frowned its defence and laughed its scorn on all beholders. The castles of the middle ages, as they are seen thousands, still majestic in their ruins, and the pleasant scenery of the rich corn and pastures and green woods of merry England; amid the vineyards and fertile plains of France; amid the marshy pastures of the Low Countries; along the steep slopes of the Rhine, the mountains of the Alps, of the Black forest, of the Pyrenees, of the Apennines, and of the mountains looking down on the Danube, relics and landmarks of a wild and iron age, the monuments of men as wild and as iron as the epoch in which they flourished.

**CASTLE OAREY**, a market town and parish in Dorsetshire, England, on the Great West-road, 129½ m. from London. It contains a manor-house in which Charles II. took refuge after the battle of Worcester.

**CASTLE CONNEL**, or **STRADBALLY**, a town in the county of Munster, Ireland; pop. of the town, 106. It is beautifully situated on the banks of the river, near the falls of Doonass, and is much frequented in summer by the inhabitants of the county for its chalybeate springs. Its castle, which was the residence of the O'Briens, kings of Munster, was destroyed during the siege of 1691.

**CASTLE DERMOT**, or **TRISTLEDERMOT**, an ancient town and parish of Leinster, Ireland; the town, 1,516. It is situated on the banks of the affluent of the Barrow, and was formerly the residence of the Dermots, kings of Leinster. It contains a great number of interesting antiquities, among which are the ruins of a cathedral, a church built by the first settlers, a Franciscan monastery, a Norman castle, a square tower supposed to have been erected by the knights templars, the remains of a priory, a castle, and in the church several curious crosses and a round tower.

**CASTLEREAGH**, **ROBERT HENRY STEWART**, second marquis of Londonderry (April 8, 1821), a British statesman, the family seat of Mount Stewart, in the county of Down, Ireland, June 18, 1769, was put to death by his own hand at his seat of North-

Cray Place, county of Kent, England, Aug. 12, 1822. He attended the grammar-school at Armagh, and completed his education at Cambridge. In 1789 he offered himself as a candidate for the representation of the county of Down in the Irish house of commons, and was elected after a sharp contest, which is said to have cost his family over £25,000. In 1794 he was sent to the British house of commons, as a member for the borough of Tregony. After the dissolution of that house in May, 1796, he was again returned to the British parliament, which met in September of the same year, as member for Orford; but relinquishing his seat in July, 1797, he was re-elected to the Irish parliament, as representative of the county of Down, and appointed keeper of the privy seal for Ireland. In the beginning of 1798, he became chief secretary to the lord lieutenant, and an Irish privy councillor. The rebellion which he invited and accompanied the landing of Gen. Humbert in 1798, was crushed by Castlereagh, although there is reason to suppose that he was not a party to the remorseless cruelties practised by the Protestants, with the odium of which his name has been loaded. It was mainly through his instrumentality, that the act of union was passed. When this measure was consummated, Lord Castlereagh quitted the Irish government, execrated by the majority of his countrymen. The Orange or Protestant party, however, to which, both by personal opinions and by family connections, and residence in the north of Ireland, he belonged, looked upon him with far different sentiments; and their respect for his staunch adherence, at any cost, to the doctrine of Protestant supremacy in Ireland, was undoubtedly shared at that time by the majority of Englishmen. He represented his native county in the first imperial parliament, which assembled in Feb. 1801, and also in the second, which convened in September of the ensuing year. In the beginning of 1802 he was appointed a privy councillor of Great Britain, and president of the board of control. He retained that office after the retirement of Mr. Pitt, and throughout the Addington administration. In July, 1805, after Mr. Pitt's return to power, Lord Castlereagh joined his cabinet as secretary at war and for the colonies. Having lost his seat for Down, he was returned in 1806 for Boroughbridge; and relinquishing his office after Mr. Pitt's death, he was returned for the following parliament, which met in Dec. 1806, for the borough of Plympton Earle. He now went into opposition against Fox and Grenville, and attacked their peace policy. In 1807, upon the formation of the Portland cabinet, he again became secretary at war, and was re-elected by his last constituency for the parliament which met in May of that year. While a member of this administration, he incurred the responsibility of the ill-advised Walcheren expedition, in reference to which Mr. Canning, his colleague and secretary for foreign affairs, assailed Lord Castle-

reagh with such warmth of personality, that a duel ensued between them in 1809, and both retired from office. Lord Castlereagh soon returned to the ministry, and assumed Mr. Canning's post, in which he gained a position so commanding, that on Mr. Perceval's death, in 1812, he had the confidence of the tory party, and was regarded as the ministerial leader in the house of commons. In Nov. 1812, he was once more returned for the county of Down, retaining that seat in the next 2 parliaments, which met in Aug. 1818, and in April, 1820. In 1814, as British plenipotentiary, he took part in the conferences of Chatillon, and was influential in persuading the allies not to lay down their arms, unless Napoleon agreed to limit France to the boundary of 1792. This Napoleon refused to do; and that great campaign was begun which ended in the capitulation of Paris, and the abdication of Napoleon. At first Lord Castlereagh's unappeasable hatred of Napoleon, or perhaps his political foresight, would not permit him to concur, in behalf of England, in the measure by which Napoleon was permitted to retain the title of emperor, and retire to Elba. After the treaty was signed, however, he reluctantly acceded to it. He took part in the congress of Vienna, and in the discussions which followed during the Hundred Days. Subsequently he supported George IV. in his schemes for getting rid of Queen Caroline, and was the author of the harsh measures for the repression of discontent caused by general distress and dearness of provisions. The struggles of the constitutionalists in Spain and Portugal called for active interference on the part of the holy alliance, and Lord Castlereagh was on the point of joining the congress of Verona, when he fell into a state of melancholy, in which he committed suicide by opening the carotid artery with a penknife. The coroner's jury which investigated the case declared the act to have been committed in a state of lunacy. Lord Castlereagh has been assailed with unsparing acrimony. As an orator, he was below mediocrity. But he had sound common sense, great moral courage, and unshaken firmness; and if he could not express his intentions fluently, he could march straight forward to their accomplishment. His correspondence was edited by his brother, the third marquis, in 1850.

CASTLETON, a post village and township of Rutland co., Vt., pop. 3,016, situated on Castleton river, at the intersection of the Rutland and Washington, and the Saratoga and Castleton railroads, which unite here with the Vermont and Canada lines. It is the seat of Castleton medical college, founded in 1818, and connected with Middlebury college.

CASTLETON, a village of Derbyshire, England, situated at the foot of a rugged eminence, on which stands Peak castle, an ancient stronghold erected by William Peveril, natural son of the conqueror, and celebrated in Sir Walter Scott's novel of "Peveril of the Peak." The

inhabitants of the village

are engaged in mining. Some, however, derive their subsistence from the manufacture of articles from spar, and from acting as guides to the strangers visiting the many natural curiosities of the neighborhood. Among the most remarkable is the Peak cavern, or Devil's Den, consisting of a series of subterranean chambers, which can only be explored by torchlight. The whole depth of the excavation from the opening is 2,800 feet.

CASTLETOWN, the capital of the Isle of Man, England, on a bay of the same name, at the S. extremity of the island; pop. 2,479. It contains King William's college, founded in 1830, and Castle Rushen, said to have been built by a Danish prince in 960. It is the residence of the governor and of the Manx court.

CASTOR, a substance somewhat resembling musk, secreted by the beaver. It is of a consistency of honey, has a strong, penetrating, fetid, and volatile odor, which is lost when the substance is dried and hardened. It is used to some extent in medicine as an antispasmodic and stimulant, and is thought to act upon the nervous system. It was formerly recommended by Pliny and Dioscorid, but has not a high reputation among modern practitioners; and as it is often largely adulterated, there will be little cause for its use to be discontinued. The article of castor which the best is obtained from Russia. The castor from the American beaver produces an inferior quality. Castoric acid is recognized among the organic compounds of which this substance consists.

CASTOR OIL, a mild purgative obtained from the nuts of the castor oil plant, *Ricinus communis*, or *palma Christi*. It is an apetalous genus of plants belonging to the natural order *euphorbiaceae*. It was introduced from a native of Asia, and was used by the ancients in antiquity, but is now naturalized in America, and the south of Europe. The characters of this genus are: Leaves alternate, palmate, glands at apex of petiole; flowers in terminal panicles; monoecious; calyx 3-5 parted, valvate; filaments numerous; polyadelphous; style short, stigmas 3, feathery; ovary globose, 3 celled; ovule in each cell; fruit capsular, 2 celled. The tribe is formed of trees, shrubs, or herbs, becoming arborescent. The *R. communis* has peltate palmate leaves, with serrated lobes; an herbaceous stem, of a purplish red color upwards; flowers in long green and glaucous spikes, arising from the divisions of the branches, and from the lower part of the spike, the upper from the upper. The capsules are primary, and vary in size in different countries. In parts of Europe it is not more than 3 feet high, but in India it is a tree, and it attains fair dimensions. The native of *R. communis* is unknown; it is conjectured to be Barbary. The castor oil plant was

lent times, both to the Egyptians and  
 ks. The latter called it croton, a name  
 ed by modern botanists on another ge-  
 euphorbiaceous plants, one species of  
 yields the strongly purgative oil called  
*tiglii* or croton oil. Numerous varieties  
*munis* exist in various localities, differ-  
 only in color and the peculiar condition  
 stem, but in stature and duration. In  
 countries it is ligneous and perennial; in  
 regions, annual and herbaceous. The en-  
 possesses active properties, but the oil  
 from the seeds is alone employed in  
 The ancients administered the seeds  
 but their variable action, producing some-  
 ven fatal effects, led to their disuse. The  
 comparatively recent introduction. The  
 were formerly known in the shops as *semi-*  
*ini* or *cataputia majoris*. They are about  
 of a small bean, obtuse at both ends, the  
 being smooth, shining, and beautifully  
 d. The skin consists of 8 tunics; the  
 or kernel consists of an oily albumen  
 embryo, the cotyledons of which are  
 anous or foliaceous. The outer shell is  
 of taste. According to Dr. Dierbach,  
 ive principle resides in the inner coat;  
 assert that the purgative principle resides  
 uryo. Mérat and De Lens have shown,  
 onnaire des sciences médicales, t. xlix.,  
 e active principle is diffused through the  
 substance of the kernel, though possibly  
 ore intensity in the embryo.—The qual-  
 castor oil depends on the greater or less  
 ty of the seeds; the peculiar variety of  
 nt from which they have been obtained;  
 accidental or intentional admixture of  
 seeds, before the process of extraction.  
 India and America much heat was for-  
 oloyed in the process, and this was in-  
 to the quality of the oil. During the  
 on of heat a volatile principle escaped  
 was so irritating that the workmen had  
 ct their faces by masks. The French  
 is the best. The fresh seeds are bruised,  
 n put into a cold press. The oil is ex-  
 and allowed to stand some time, to per-  
 albumen, mucilage, and other matters  
 ide; or it is filtered, to separate them  
 idly. The produce is equal to about  
 seeds employed, and the oil possesses  
 atural qualities. Both the French and  
 oils are much milder than oil procured  
 opical countries. Oil of good quality  
 kish fluid of a very pale yellow color,  
 being almost limpid, with a slightly  
 odor and an oily taste, mild at first,  
 ; a feeling at the back of the throat,  
 less intense, according to the freshness  
 specimen. Bad oil is rancid and disa-  
 a.—When pure, it is a mild aperient or  
 , operating without griping or other in-  
 ence, and commonly very soon after it  
 . It is deemed the most proper laxative  
 y inflammatory states of the abdomen,  
 leys, or the bladder. It is also deemed

a most eligible medicine in piles and other affec-  
 tions of the rectum. Alone or with turpentine,  
 it is very efficacious in expelling worms. The  
 chief objection to its use is the repulsive taste.  
 From 15 to 20 drops of pure liquor potasse will  
 usually saponify half an ounce of castor oil, to  
 which 1 ounce of distilled water and a drachm  
 of spirit of pimento or of nutmeg may be add-  
 ed, to make an emulsion, which is equally ef-  
 fective and not unpleasant to the taste. Castor  
 oil is much used in the East, France, Italy, and  
 other countries, for burning, as well as for me-  
 dicinal purposes.—The manufacture of castor oil  
 is actively carried on in the U. S., especially at St.  
 Louis, the beans being produced in southern Il-  
 linois. The ground is prepared as for other crops,  
 and the seeds are planted much in the manner  
 of those of Indian corn, with the exception that  
 there is but one seed put into each hill, and that  
 at every 4th row a space is left to admit of the  
 passage of a team for the purpose of gathering  
 the crop. The ripening commences in August,  
 about 20 bushels from an acre of ground is  
 considered a fair yield. The ordinary hydraulic  
 press was first applied to the manufacture by  
 Mr. Henry T. Blow, about 1847. Mr. Blow's  
 manufactory was the most extensive in the U.  
 S., but was destroyed by fire in the early part  
 of 1856. A new press introduced by Mr. La-  
 tourette and patented Oct. 28, 1851, has in-  
 creased the product of oil from the bean 37½  
 per cent. over the ordinary hydraulic press, and  
 brought the manufacture in many other re-  
 spects to a higher degree of perfection. On an  
 average one of these presses is estimated to  
 work 150,000 bushels of beans per annum, pro-  
 ducing 400,000 gallons of oil. The produce in  
 4 years, 1850 to 1853, averaged an annual yield  
 of about 286,000 gallons, most of which was  
 taken for home consumption.—The following  
 table presents the movement of the American  
 trade with foreign countries in castor oil during  
 the year ending June 30, 1857.

CASTOR AND POLLUX, called also the  
 Dioscuri, or sons of Jupiter, famous heroes in

Greek mythology. According to Homer, they were sons of Tyndareus and Leda, and brothers of Helen and Clytemnestra, and hence are often called the Tyndaridæ. Castor excelled in taming horses, and Pollux in the game of boxing. Though buried, they were taken from the earth before the siege of Troy, became immortal and honored as gods, and sometimes appeared among men. The legend was complicated by subsequent poets. According to some, the Dioscuri were sons of Leda and of Jupiter disguised as a swan or a star; according to others, Pollux only had this divine origin and the privilege of immortality. The place of their birth was variously said to be Amyclæ, Mount Taygetus, and the island of Pephnos. They are fabled to have attacked and ravaged Attica, and to have brought back their sister Helen who had been stolen away by Theseus. They took part in the Calydonian boar hunt, and accompanied the expedition of the Argonauts, during which Pollux vanquished with the cestus the giant Amycus, king of the Bebryces, and founded the city of Dioscurias in Colchis. Associated with Idas and Lynceus, sons of Aphareus, they plundered Arcadia, but in a quarrel which arose concerning the division of the spoil, Castor, the mortal, perished by the hands of Lynceus, who in his turn fell under the blows of Pollux, while Idas was struck with a thunderbolt by Jupiter. According to another tradition Castor was slain in a war between Athens and Lacedæmon. Jupiter permitted Pollux to pass alternately one day with his brother on Olympus and another on the earth. The worship of these heroic brothers was established by the Achæans, adopted by the Dorians, and spread throughout Greece, Italy, and Sicily. They were the tutelary gods of hospitality, presided over gymnastic exercises, and were eminently the mighty helpers of man. They calmed tempests, appearing as light flames on the tips of the masts. They sometimes appeared in battle, riding on magnificent white steeds at the head of the army. By their assistance the Romans believed themselves to have gained the battle of Lake Regillus. Placed among the stars they became the constellation Gemini. In works of art, they are usually represented as young horsemen in white attire, with a purple robe, armed with the lance, and wearing a helmet crowned with stars. At Rome the men swore by the temple of Pollux, *Ædepol*, and the women by that of Castor, *Æcastor*. There was an ancient temple consecrated to them in the Forum, around which the *Equites* marched in magnificent procession every year on July 15.

CASTOR RIVER rises in St. Francis co., Mo., flows S., communicates by several arms with a group of small lakes in Stoddard co., and afterward unites with the Whitewater river. The stream thus formed, which is sometimes called the Castor, but more frequently the Whitewater, flows through a low swampy region, in which most of the streams spread themselves over a large surface and form extensive marshes or

lakes. It receives the outlet of Lake Pemina, and finally discharges itself into Big lake.

CASTREN, MATTHEW ALEXANDER, a Finnish philologist, born Dec. 2, 1813, at Tervola, Finland, died May 7, 1852, in Helsingfors. He devoted himself to collecting the monuments of the genius of Finland, scattered through various tribes, and as a preparation he took to travel on foot in 1836 through Lapland. Aided by government, he pursued his investigations through Norwegian and Russian Finland, and even as far as the borders of Europe and Siberia. He also sought to make himself more familiar with the language, with a view to the translation of the Swedish of the celebrated popular poem "Kalevala." He was appointed ethnographer to the academy of St. Petersburg, and with the aid of the university of Helsingfors, he extended his researches through Siberia, from the frontiers of China to shores of the Arctic ocean. With feeble constitution and delicate health, he accomplished extraordinary labors, and sent home, in addition to the documents connected with his own studies, reports and letters of great value. Many of these were published in Finnish and Swedish periodicals of the day. He was honored on his return to Helsingfors in 1851, a year before his death, with the office of first professor of the Finnish literature at the university of Helsingfors. The literary society of Finland and the academy of St. Petersburg caused his writings to be published after his death, the latter by appointing Mr. Schiefner as editor of the collection. It was published in St. Petersburg in German in 1856, while Finnish editions were published at Helsingfors in 1852, 1853, and 1854. A German edition of part of them was published in Leipsic. His Samojed grammar and vocabulary were published in St. Petersburg by Schiefner in 1854 and 1855, and his dictionary in 1857. A biographical notice of Castren, by Mr. Borg, appeared at Helsingfors in 1853, and in the same city a monument has been dedicated to his memory.

CASTRES, a flourishing town of France, pop. 14,144, in the department of Tarn, 26 m. S. E. of Albi, lying in a fertile valley on both sides of the river Agout, which is here crossed by 2 stone bridges. It is the seat of a Protestant consistory, having been one of the first towns to embrace the doctrines of Calvin. It has manufactures of silk, woollen, and cotton goods. Castres was founded by the Franks, A. D. 647; suffered much in the religious wars of the 16th century; its fortifications were destroyed by Louis XIII. in 1619. It was long the residence of Henry IV. during his religious wars.

CASTRO, INES DE, wife of Pedro of Portugal, born in the first part of the 14th century, assassinated in 1355. She was a daughter of Don Pedro Fernandez de Castro, a descendant from the royal house of Castile, and a maid of honor to Constantia, 1st wife of Pedro. After

Infanta's death in 1344, Pedro, fascinated by the extraordinary beauty of Ines, contracted a marriage with her, which, when a year afterward it was disclosed to his father, Alfonso IV., met a violent opposition on the part of this king, who feared the influence exercised by one of the brothers of Ines, in apprehension that the children of Ines would interfere with the claims to the throne of his children by his first wife, also preyed upon the mind of Alfonso. Her death was reprobated, and while Pedro was away from the kingdom on a hunting excursion, the king proceeded to Coimbra with the intention of murdering him, but when he arrived there and beheld the beautiful woman, surrounded with her children, and imploring his mercy, he was softened by pity. Eventually, however, he yielded to the evil suggestions of his advisers, and Ines was assassinated. When Pedro returned home and found, instead of the lovely queen, the bleeding corpse of his wife, his rage and wrath knew no bounds, and his cruelty toward the archbishop of Braga succeeded with the greatest difficulty in reconciling him with the king, and in appeasing his thirst for vengeance. After the death in 1357, this thirst, however, was quenched with increased fury. Only one of the assassins of Ines, Diego Lopez Pacheco, escaped, and fled to Aragon. The other two, Joelho and Alvaro Gonsalvez, who had been under protection at the court of Pedro the First of Castile, were surrendered in exchange for the Castilian prisoners to Pedro of Portugal, after subjecting them to the most cruel tortures, had their hearts torn out of their bodies, and the ashes scattered to the winds. His regard for the memory of his wife did not rest here. He convened a council at Castanheda, when, in the presence of the nobility and the court officials, he produced the papal documents and the licence of the archbishop of Guarda, the diocesan priest, in order to establish an irrefragable proof of the legitimacy of his marriage with Ines. The proceedings of this council were published all over the kingdom, and the hope of Pedro was to have the remains of his wife exhumed. Her corpse was put upon the funeral pile, clothed with the insignia of royalty, and after another, the dignitaries of the court approached to kiss the hem of the garment. Ines was afterward buried with pomp at Alcobaça, the king, the bishops, knights and officers of Portugal following the funeral procession on foot. The road from Coimbra to Alcobaça over which it passed, extending over 60 miles, was literally covered with a multitude of people, who stood on both sides with their hands joined in prayer. A superb monument was dedicated to her at Alcobaça. Gomes de Souto, the count of Soden in Germany, and a Dutchman, have founded tragedies upon incidents of Ines de Castro's life. But the most remarkable tribute paid to her memory is

that of the great Portuguese poet Camões in the "Lusiad."

**CASTRO DEL RIO**, a Spanish town on the Guadajoz, province of Cordova; pop. in 1852, 8,851. The ancient part of the town is surrounded by a dilapidated wall with towers. The entrance is by a single gate, once defended by an Arab castle, now in ruins. The modern portion is outside the walls, and is well and handsomely built. There are 2 colleges and several schools, convents, chapels, hospitals, and factories of various kinds. The town has a trade in wheat, cattle, oil, honey, &c.

**CASTRO URDIALES**, or **CASTROURDIALES**, a seaport town of Spain, on the bay of Biscay, in the province of Santander; pop. in 1852, 8,810. It was sacked by the French in 1811, but has since been neatly rebuilt. A ruined convent of the templars is in the vicinity. It has a safe harbor, and extensive fisheries.

**CASTRO VIREYNA**, a Peruvian province, in the department of Ayacucho; pop. about 15,000. The capital, bearing the same name with the province, is situated on the W. slope of the Andes, at the head of a small stream falling into the Pacific. The climate is healthy, though cold; the pasturage good; fine sheep are reared, and a beautiful quality of wool, from the vicuña, is produced here.

**CASTROGIOVANNI**, or **CASTRO GIOVANNI**, (anc. *Enna*), a city of Sicily, in the district of Caltanissetta, pop. about 12,000, on a plateau in the centre of the island, 4,000 feet above the sea. The climate is healthy, the soil fertile, and water abundant. The old feudal fortress of Enna is the chief edifice. It was the fabled birth-place of Ceres, and the site of her most famous temple. About 5 m. distant is the lake of Pergusa, where Proserpine, according to the poets, was carried off by Pluto. During the first servile war the insurgent slaves made Enna their head-quarters.

**CASTRUM DOLORIS**, or castle of mourning, called in French *chapelle ardente*, is the room, whether it be a chamber, chapel, or church, in which a catafalco is erected at the burial of a prince or other distinguished personage. This room is hung with black, adorned with the arms and the likeness of the deceased, and lighted with numerous wax tapers. In the middle is the catafalco, or lofty tomb of state, upon which the coffin, usually empty, is placed. This is covered with memorials of the rank and dignity of the departed, with his insignia of office and orders, and with his sword and epaulets. Above this hangs a canopy, and high chandeliers stand about it.

**CASVEEN**, **CASBIN**, **KASHIN**, **KASBIN**, or **CASBEEN**, a fortified city of Persia, in the province of Irak-Ajeme, 90 m. N. W. of Teheran, lat. 36° 12' N., long. 49° 53' E.; pop. estimated at 60,000. It is surrounded by brick walls, with towers, and is said to exceed Teheran in extent; but whatever grandeur it may have once possessed has been destroyed by repeated earthquakes. Whole streets lie in

ruins, and most of the ancient buildings have been overthrown. The palace, though much dilapidated, is still occupied by the governor. A mosque with a large dome, bazaars, schools, and baths are the other principal buildings. The chief manufactures are velvets, brocades, a coarse cotton cloth called kerbas, carpets, sword-blades, and wine. Grapes and nuts are produced abundantly, and of good quality. Casveen is also an entrepot for the silks of Ghilan and Shirvan destined for Bagdad and India, and for rice from the Caspian provinces. The surrounding plain was formerly one of the most productive districts of Persia, its natural fertility being greatly enhanced by a vast system of irrigating canals, most of which are now choked up, except in the immediate vicinity of the city. Casveen was founded about the middle of the 4th century, and under the Suffide dynasty became the capital of the kingdom. The removal of the seat of government to Ispahan checked its prosperity, though it still has much commercial importance.

CASWELL, a co. in the N. part of N. C., bordering on Va.; area 400 sq. m.; pop. 15,269, of whom 7,770 are slaves. It is intersected by Hycootee river and County Line creek, affluents of Dan river. The surface is undulating, and the soil fertile. The productions in 1850 were 75,243 bushels of wheat, 111,891 of rye and oats, 417,509 of Indian corn, 2,282,939 lbs. of tobacco. There were 24 corn and flour mills, 4 saw mills, 1 iron foundery, 1 cotton factory, 9 tobacco manufactories, 26 churches, and 1 newspaper. It was organized in 1777, and named in honor of Richard Caswell, the first governor of the state under the constitution. Capital, Yancey.

CASWELL, RICHARD, first governor of North Carolina, and brigadier-general in the army of the American revolution, born in Md., Aug. 8, 1729, died Nov. 10, 1789. In 1746 he removed to N. C., where, in 1754, he became a member of the colonial assembly, in which he continued to hold a seat till 1771. He was then chosen speaker of the house of commons, and colonel of the county militia, and at the outbreak of the revolution identified himself with the patriots. He soon after became treasurer of the state. In 1776, in command of a regiment of minute men, he defeated the loyalists at Moore's creek, and for this service was appointed brigadier-general. For 3 years he was president of the provincial congress which framed the state constitution, under which he was elected the first governor. He was engaged in the disastrous battle of Camden in 1780, became comptroller-general of the state in 1782, and was again elected governor in 1784, to which office he was twice reelected. In 1787 he was a delegate to the convention assembled at Philadelphia for the formation of a federal constitution; in 1789 he was speaker of the state senate, and he was subsequently one of the convention by which the federal constitution was ratified in N. C. He

was presiding in the senate when he was with paralysis, which proved fatal.

CAT (*Felis*, Linn.). The Linnaean comprises about 50 species of mammalia, the characters of which are assimilated, and at the same time widely different from other genera. It is characterized by 6 incisor teeth above and below; 6 teeth in each jaw, powerful and adapted for tearing; molar or cheek teeth, 4 in the upper jaw and 3 in the lower, thin, pointed, wedge-shaped, formed for cutting. The eye is large, round, and wide; the eye pupil often oblong; the tongue is covered with horny papillae, directed backward. The claws are formed for walking; the toes are 5 on the fore feet, and 4 on the hind feet, armed with strong, sharp, and hooked claws, which are retracted when the animal walks. The claws are very short, as in all animals that feed most exclusively on animal food. The members composing this genus (which include the tiger, panther, &c.) are the most powerful and ferocious of all predatory quadrupeds. Eagles and birds of prey are among their favorite tribes. The different species are distributed over every portion of the globe, with the exception of Australia and the South Pacific, but the most formidable are found in the warmest climates; no species has been introduced to the old and the new world. The favorite resorts of these animals are the forests of the tropics, where they lie in wait during the day, and prowl at night in search of prey; the more northern and small species prefer rocky and well-wooded situations. Cats hunt a living prey, which they catch by cunning and watchfulness, springing suddenly on unsuspecting victims from an ambush, or stealthily crawling up to them. Some, as the leopard and jaguar, pursue their prey into trees; the cougar lies in wait on a precipice or overhanging rock, and falls upon the passing beneath. Their aspect is fierce, and their instincts bloody, and their voice is great; even their voice has sometimes a harsh and terrible sound. The anatomical structure of the cats is indicative of great strength and activity; the jaws are very powerful, the teeth shaped like wedges, thin and pointed, requiring but little force to cut through the flesh on which they feed; the structure of the skull admits of no lateral motion, and the force of the immense temporal and occipital muscles is exerted in a perpendicular direction. To assist in tearing their prey, the surface of the tongue is covered with horny papillae; these may be felt, like a rough scale, on the tongue of the domestic cat. The tongue is rather an organ for removing the soft parts from bones, and for retaining the food in the mouth, than an organ of laceration. The neck, shoulders, and fore limbs exhibit a remarkable muscular development; they can drag away with ease cattle and horses which they have killed; a single blow of the fore

tiger has been known to fracture a skull. The mechanism by which their claws are retracted and prevented from being extended during walking, is as follows: the claw itself is supported on the last bone, which consists of 2 portions united to each other at a right angle; the articulation is at the distal end of the vertical portion, while the tendons are attached to the other portion. The action of these muscles causes the claw to move through an arc of 90° at the end of the second bone. In the state of rest the claw is kept retracted by a strong extensor muscle, and by elastic ligaments; in the state of action, the strong tendon of the flexor, with its circular sweep, protrudes the claw with prodigious power.—With their claws and admirable destructive weapons, carnivora play an important part in the economy of nature; without their agency the numerous animals on which they prey would be too numerous for the food provided for their sustenance, and would thus be the cause of their own extinction. Man also reaps a direct benefit from the trade in their skins, of which immense numbers are used in China as robes of rank, in Russia as real necessities for the winter season, and in Europe as ornaments.—The domestic cat is generally supposed to have sprung from the *felis maniculata* (Ruppel), a native of the north of Africa. This species is 2 feet 5 inches long, of which the tail measures 9 inches; the height at the shoulder is 9½ inches; in size it does not differ from the domestic cat. The color above is an ashy gray, with a darker line along the back; beneath, grayish white; on the forehead are slender black lines, running backward to the sides of the neck; the cheeks, throat, and front of the neck are pure white; 2 lines of an ochre-yellow color, one from the outer corner of the eye, and the other from the middle of the cheek, meet under the ear, and 2 rings of the same color encircle the white of the neck; the limbs have 5 or 6 blackish micircular bands; the heels and wrists are black; the tail is slender, and has 2 dark rings to the tip. There is no doubt that this species is the original of the domestic cat of ancient Egyptians, as is shown by the representations of cats on their monuments, mummies, and by the skeletons found in their tombs. It may be a question whether the domesticated species was transferred by the ancients to the antique nations of Europe. There is only one cat often met with, in modern times, which is a white cat, possessing the most striking resemblance to the Egyptian species; other varieties of our domestic cats resemble the wild species of Europe. It is probable, therefore, that all our domestic animals, different nations have domesticated different small kinds of native cats, which have produced, by the mixture of their closely allied species, the various varieties now observed. At the same time it should be remembered that the whole

genus *felis* is susceptible of considerable variation; slight variety of color, therefore, does not necessarily imply diversity of origin. Temminck and Ruppel are of the opinion that the *felis maniculata* is the species from which our domestic cat has sprung; before them most naturalists believed that the wild cat of Europe was the original stock; it is altogether probable that the domesticated species has been crossed in many instances by the wild cat, as shown by the short legs and thick short tails of some varieties. All the small species of cats might be easily domesticated, though the common Egyptian species seems to be the only one generally employed in household economy. The domestic cat readily returns to a wild state; neglect, insecurity of their young, or favoring circumstances, drive or tempt them to the woods, where they prowl and hunt, and breed, in the manner characteristic of the genus. Cats, though they prefer flesh, will eat bread, fish, insects, and almost any thing that is eaten by man. As a general thing, they have a great dislike to water, and will rarely enter it for the purpose of catching fish, of which they are extremely fond. They are capable of very strong attachment to man, and to animals reared with them. Among the most remarkable varieties of the domestic cat, are the Maltese or Chartreuse cat, of a bluish gray color; the Persian cat, with long white or gray hair; the Angora cat, with very long and silky hair, generally of a brownish white color; and the Spanish or tortoise-shell cat, the most beautiful of all. In Cornwall and the Isle of Man, a breed of cats without a tail is quite common, analogous to a similar and more common breed of dogs.—The common wild cat (*felis catus*, Linn.) is the only animal of the genus that inhabits the British islands, where it is still not uncommon in the wild districts of Scotland and Ireland; it is found in the wooded tracts of the European continent. The length of the wild cat is 38 inches, the tail being 11 inches. The fur is long and thick, but not shaggy; the color varies from a yellowish to a blackish gray, darkest on the back, where it forms a line, diverging into 4 on the neck and head; the sides are brindled with broad, dark, but indistinct bands; the legs have 2 or 3 black bars, running transversely upward; the tail is thick, with black rings indistinct toward the base, and a black tip. The wild cat is an active climber; its food consists of small animals and birds; its depredations among game are frequently very great. There are no long-tailed wild cats in North America; the animal called wild cat here is a species of lynx. (See *BAR LYNX*.) The catamount is the cougar of authors. (See *COUGAR*.) There are several small species of cats in the East Indies: the Sumatran cat, *felis minuta* (Temm.), and *F. Javanensis* (Horsf.); the Bengal cat, *F. Bengalensis* (Desm.); Diard's cat, *F. Diardii* (Desm.), and the Nepaul cat, *F. Nepalensis* (Horsf.).  
CATAOUSTIC. See CAUSTIC.  
CATACHRESIS (Gr. *κατα*, against, and *χρησις*,

use), a rhetorical figure by which a word is put to a different usage from that which it had originally, being borrowed from one idea to express another. Thus Milton, describing Raphael's descent from heaven, says, "He *sails* between worlds and worlds." This figure is common in the speech of daily life, as in the example, "Tears *speak* louder than words." The term catachresis is sometimes limited to the abuse of a trope, when a word is wrested too far from its true signification.

CATACOMBS (*kata*, downwards, and *κρυβος*, a hollow place), subterraneous places for burying the dead. The catacombs of Egypt, from their vast size, extent, and elaborate pains spent upon them in decorations, both of architecture and painting, are perhaps more remarkable than any others. The most ancient are those of the Theban kings, which can be traced for a period of 3,000 to 4,000 years. It is supposed that the ancient Egyptians spent such enormous sums on their tombs and processes of embalming, from their belief that the soul would revisit the body if this were preserved from decay; and hence resulted their stupendous catacombs, which to this day interest and astonish the traveller. The entire chain of mountains in the neighborhood of Thebes is mined by an immense number of catacombs. Those of the kings, originally 47 in number, have been mostly defaced, but a few still exist to bear witness to the pristine magnificence of these sepulchres. They occupy a deep ravine, flanked by the bed of a torrent in the centre of the mountain Libycus, and, lying some 6,000 to 7,000 paces from the banks of the Nile, were reached by an artificial passage. Proceeding along the valley, the wanderer discovers openings in the ground, with a gateway in a simple square frame, each gateway being the mouth of a gallery leading to the royal sepulchre. Forty paces within is another gateway opening to a 2d gallery 24 feet in length, and on each side of this are small chambers. A 3d gallery succeeds, communicating with a chamber 18 feet square, and from this is an entrance to another gallery 64 paces in length. This in its turn connects with several small apartments, beyond which lies a saloon 20 feet square, containing the royal sarcophagus. The whole extent of excavation in this single tomb is upward of 225 paces. All the sarcophagi of the kings have long since been violated, and the bodies destroyed, doubtless for the sake of plunder. M. Denon, the French traveller, found, however, in one of the royal tombs, the fragments of a mummy. Robbed as they have been of their royal clay, these tombs still preserve their wonderful paintings, after in some cases a lapse of 4,000 years; the more costly of the catacombs are covered in the whole extent of their interior by hieroglyphics and pictures, generally in fresco, and in all, unless wantonly injured by the Arabs, the colors are as fresh as if laid on but yesterday. The catacombs of the opulent of the ancient Thebans were lower on the mountain than the

royal sepulchre, and were the residence of their families. They were richly decorated, and the paintings are brilliant, and finely executed. Innumerable are these tombs, one containing warlike representations, another of husbandry or agriculture. Every occupation or amusement is exhibited, as fishing, feasting, &c. Many of the paintings are colored yellow on a blue ground, as a homage paid to the sun, the religious or funeral procession, the various phases of human life, the various occupations of the gangs of African negro slaves, and accurately drawn in all their characteristics, such as thick lips and wavy hair, and are adduced by some to believe the theory of the negro race, as one of the strongest arguments showing at least that, notwithstanding the influence of the negro being confined to the influence of climate through such a long time, his type was precisely the same as in B. C. In a group of a double row of Nubians, bound, and driven by the king of Rhamses II., at Abou Sambo, the king with perfect accuracy all the characteristics of the modern Ethiop. The paintings of the Egyptian catacombs also exhibit the various phases of human life, as the lossal or pigmy size, as well as the various forms of the gods, and fox-headed deities. The paintings of the ancient Egyptians may be compared to the paintings of the modern Egyptians, as every action of the former is represented with accompanying figures, down to the playthings of the children. "The Manners and Customs of the Egyptians," by Sir Gardner, contains many hundreds of drawings, plates directly copied from the various frescoes, and make the traveller intimately acquainted with the habits of the extinct people, that he seems to be in hand with the former. The paintings of the Nile. The catacombs were limited in space, and were in color and unadorned. In the catacombs the mummies were packed together, and could be laid, tier upon tier, leaving a narrow passage between the walls of the galleries. It is calculated that, during the period of mummification was in vogue, not less than 400,000,000 mummies were tombed in the Egyptian catacombs, during the whole period of the existence of the Roman catacombs at Rome, and more especially during the first three centuries. Connected as the history of the early martyrs of the Christian religion and history has been, the favorite branches of the study of the antiquaries are of great antiquity, and the quarries hewn by the Romans, and the tombs of Romulus and Remus, and the tombs of the 7 hills on which the city of Rome was founded.

d honey-combed by passages, dark gal-  
w corridors, and vaulted halls, where  
never enters. The light and soft na-  
he material to be quarried greatly facil-  
ie work, and allowed the workmen to  
eir shafts and galleries as they pleased;  
vations being made in the soft volcanic  
d *pozzolano*, another volcanic sub-  
ven softer. As the extent and wealth  
ty increased, new quarries were contin-  
ened, even miles from the banks of the  
nd continued to be sought through the  
of the Cæsars, until the empire began  
, and old edifices were resorted to as  
s for new ones. None of the ancient  
have left any account of the uses of  
cesses when they were no longer quar-

Horace, speaking of the caverns under  
uline hill, says: "This was the com-  
pulchre of the miserable plebeians."  
the time of the persecutions of the  
ns, commencing with that under Nero,  
wed by those of Domitian, Trajan, Had-  
verus, Maximinus, to what is called the  
last persecution, which began in A.D.  
der Diocletian, the catacombs were  
with those for whom there was no  
the face of day. It is conjectured that  
these sufferers were aided in obtaining  
iding-places by the fossors or workmen  
caverns, who were well acquainted  
ir intricacies, and who became them-  
early converts to the new faith. It  
until the year 1377, when the papal  
ich for nearly 70 years had been at  
, was restored to Rome, that the cata-  
ppear to have attracted any serious at-  
from the government or the clergy.  
s doubtless owing to the frightful state  
y, which, for some centuries after the  
n of the western empire, rendered  
ttle better than a robbers' stronghold,  
lly forced the pontiff to flee from the  
d seek an asylum on the banks of the

At this period the catacombs, from  
een the habitations of persecuted Chris-  
re thronged with outlaws and assassins;  
ie papal authorities acquired strength,  
them were driven from their lurking  
nd the entrances to many closed. About  
ider Pope Paul III., some few of the  
arkable of the crypts were explored,  
and lighted by lamps. A deep inter-  
subterranean Rome having thus been  
ed, Father Bosio, a humble priest, but  
usiastic antiquary, spent more than 30  
his life, from 1567 to 1600, in digging  
ping in the catacombs; he cleared the  
some of the innermost recesses which  
n blocked up for centuries, and made  
s of the ancient monuments, inscrip-  
aintings, sculptures, lamps, vases, &c.,  
nderground. He did not live to see his  
ublished, as he died while writing  
chapter, but it appeared in 1682,  
by Father Severani, and under the

title of *Roma Sotterranea*. It was translated  
into Latin by Father Aringhi, and still forms  
the most important work on the Roman  
catacombs. He was followed by Father Bol-  
detti, who also spent more than 80 years in his  
subterranean research, and published in 1720 a  
folio volume, entitled "Observations on the  
Cemeteries of the Holy Martyrs and Ancient  
Christians of Rome." This work is exceedingly  
valuable. These two enthusiastic and meritori-  
ous priests have been succeeded by such inves-  
tigators as Bottari, Marangoni, Lupi, Fabretti,  
Filippo Buonarrotti, Allegranza, &c. Seroux  
d'Agincourt is one of the most distinguished au-  
thorities of modern times; he went to Rome in  
the latter part of the last century to study Chris-  
tian archæology and remain there for 6 months,  
but he became so interested in his inquiries  
that he stayed nearly 50 years. His great work,  
*Histoire de l'art par les monumens, depuis sa dé-  
cadence au 4<sup>e</sup> siècle jusqu'à son renouvellement  
au 16<sup>e</sup>*, treats of the catacombs with profound  
learning and discrimination. M. Perret, a French  
architect, who accompanied the army sent by  
Louis Napoleon to the aid of Pius IX., has been  
for some years engaged in a work upon the cata-  
combs. It is not finished, but promises to be far  
superior to any on the subject which have yet  
appeared. When Bosio's discoveries were made  
known, Pope Clement VIII. took the cata-  
combs under his special protection, and de-  
creed excommunication and severe corporal pun-  
ishment against any one who should enter them  
without leave, or remove from them the least  
object whatsoever. They have from that time  
been regarded with peculiar veneration, from  
their history as hiding-places for the early Chris-  
tians. Although neglected by the government  
for many ages, they had attracted the notice of  
the pious since the beginning of the 4th cen-  
tury. So highly were the virtues of the Chris-  
tian martyrs esteemed, that personages of the  
highest distinction were buried in the cata-  
combs, and were happy if they thought that  
after their death such honor should be paid to  
their remains. Among illustrious men thus  
entombed were the popes Leo I., Gregory the  
Great, Gregory II. and III., and Leo IX.; and  
the emperors Honorius, Valentinian, and Otho  
II.—The catacombs of Naples are of greater ex-  
tent than those of Rome; they are not subter-  
ranean, but excavated in the volcanic tufa in the  
face of the hill of Capodimonte, forming a long  
series of corridors and chambers, arranged in 8  
stories communicating with each other by steps.  
The only entrance now open is that of the  
church of San Gennaro. Their construction  
has given rise to many speculations among the  
antiquaries of Naples, but is now generally as-  
cribed to the colonists from Greece. Subse-  
quently they were used by the early Christians  
for purposes of sepulture as well as of worship.  
St. Januarius and other martyrs were interred  
here. In the middle of the 17th century they  
were made the burial place of the victims of  
the plague, and at the beginning of this century,

several bodies were found by Abbé Romanelli.—The catacombs of Syracuse are larger and better preserved than any other catacombs, and not of so gloomy an appearance as those of Rome and Naples. They form an immense subterranean town, with innumerable tombs cut out of the solid rock, containing the dead of all ages, nationalities, and creeds. They were converted by the early Christians into places of refuge from persecution. The entrance to them is under the church of San Giovanni.—The catacombs of Malta are of small extent, but in good preservation. They are subterranean, and seem to have been used for a place of worship as well as of sepulture.—The so-called catacombs of Paris were never catacombs in the ancient sense of the word, and not devoted to sepulchral purposes until the year 1784, when the council of state issued a decree for clearing the cemetery of the Innocents, and for removing its contents, as well as those of other graveyards, into the quarries which had existed from a remote period beneath the southern part of Paris, and by which the Observatory, the Luxembourg, the Odéon, the Val de Grâce, the Panthéon, the streets La Harpe, St. Jacques, Tournon, Vaugirard, and many others were completely undermined. Some excavations having taken place, a special commission was appointed to direct such works as might be required. Engineers and workmen were immediately employed to examine the whole of the quarries, and prop the streets, roads, churches, palaces, and buildings of all kinds which were in danger of being engulfed. The plan of converting the quarries into catacombs originated with M. Lenoir, lieutenant-general of the police, and every preparation was made by sinking a shaft, propping up the cavities, and walling off various portions for receiving their future contents. The ceremony of consecrating the catacombs was performed with great solemnity on April 7, 1786, and on the same day the removal from the cemeteries began. This work was always performed at night; the bones were brought in funeral cars, covered with a pall, and followed by priests chanting the service of the dead, and when they reached the catacombs, the bones were shot down the shaft. Such tombstones, monuments, &c., as were not claimed by the families of the deceased, were arranged in a field near the entrance of the shaft, and among these relics was the leaden coffin of Madame de Pompadour. As other cemeteries were suppressed, the bones from them were removed to this general deposit by order of the government. The catacombs served also as convenient receptacles for those who perished in popular commotions or massacres. At first the bones were heaped up without any kind of order, except that those from each cemetery were kept separate; but in 1810 a regular system of arranging them was commenced, and the skulls and bones were built up along the wall. The principal entrance to the catacombs is near the *Barrière d'Enfer*,

but for some years has been strictly into a dangerous state of the ruins of the From the entrance a flight of 90 steps leads to the catacombs; a series of passages are seen branching in several hundred yards from the entrance. The entrance is a large vaulted dome, of octagonal form, and over the following inscription: *Hic quiescunt beatam spem habentes. The vault opens into a long gallery, from the floor to the roof, the thigh bones are in front, close piled together, and their united by three rows of skulls at equal distance. Behind these are thrown the gallery conducts to several chapels, lined with bones. One is called the "Tomb of the Rev.," the other the "Tomb of Victims," the bodies of those who perished in the period of the revolution, or in the month of September. Calculations differ as to the number of bones collected in this vast charnel-house; it is estimated to contain at least of 3,000,000 human beings. The catacombs and quarries under the city were very lately drawn up by the municipal authorities. These contain 8,000,000 metres square in extent, or  $\frac{1}{10}$  of the total superficies of Paris.*

**CATACOUSTIC**, relating to Acoustics.

**CATAFALCO** (an Italian word of origin), the decorated tomb or altar in the *castrum doloris*. The final interment of Michelangelo was of unexampled magnificence.

**CATAGOGIA**, or feast of the return, a festival celebrated at Eryx, in Sicily, in honor of Aphrodite. It was preceded by the feast of the *anagogia*, during which it was believed that the goddess went over to Africa accompanied by all the pigeons of the neighborhood. They returned 9 days afterward, and the entrance of the first pigeon into the temple was the signal for general rejoicing and feasting. The whole district was said at this time to smell of butter, which was regarded as a sign that Aphrodite had returned.

**CATAGRAPHIA**, or forebortening, are said to have been the invention of Cimon of Cleonæ, who probably flourished in the time of Solon, and drew the human figure in a variety of attitudes. He first made muscular articulation, indicated the veins, and gave natural folds to drapery. Pliny uses the term *catagraphe* to denote any oblique view of the countenance or figure, either in profile or otherwise.

**CATAHOULA**, a parish of Louisiana; area 1,970 sq. m.; pop. 7,182, of whom 2,526 are slaves. It is watered by the Washita, Texas, Black, and Little rivers, several of which are navigable by steamboats through the parish and on its borders. Near the Washita river the surface is partly occupied by hills. The soil is

is fertile, and lies upon a bed of  
me. The productions in 1850 were 6,648  
cotton, 188,786 bushels of Indian corn,  
of potatoes. There are 14 churches  
newspaper, and 548 children attending  
L. The parish was organized in 1808.  
Harrisonburg.

CATALANI, ANGELICA, an Italian singer,  
in 1784, at Sinigaglia in the pontifical  
died in Paris, June 12, 1849. Her  
worked during the day in the shop  
jeweller, and in the evening played  
born in the theatre. Angelica, when  
7 years old, attracted general attention  
remarkable power and purity of her  
People went in such numbers to the  
ent of St. Lucia, near Rome, where she  
red her education, to hear her, that the  
had to check the pressure of the crowd.  
ca, however, continued to sing, and on  
the convent in 1798 she passed through  
of scientific musical studies. Toward  
while her artistic culture was still rather  
lete, a theatrical manager in Venice pre-  
on her to appear as Lodoisca, in May-  
of that name, and she was successful.  
y she continued to sing at Venice, and  
after making a tour through the different  
of Italy, she performed at the Italian  
Lisbon. Afterward she went to Madrid,  
re receipts of her first concert amounted  
11,000. Subsequently she went to Paris,  
for 2 concerts at St. Cloud Napoleon  
her \$900, beside a pension of \$210, and  
her the free use of the opera house  
concerts, of which the receipts amount-  
to \$9,000. In London she received \$13,000  
first, and \$17,000 for each of the  
7 seasons, beside 2 benefits which  
\$11,000, and permission to perform  
provinces. For some time she was  
l with the management of the Paris  
in coöperation with her husband, M.  
ibrègue, formerly a captain in the French  
r. In this enterprise she was not suc-  
l. Her clear, powerful voice electrified  
English, especially in "God save the King;"  
her influence over continental audiences  
not so great. In 8 years she cleared about  
5,000. She sang in Germany, Denmark,  
len, Poland, and Russia, returning also  
tionally to her native country, and after-  
again made her appearance in Paris,  
without meeting with great success.  
1830 she withdrew from the stage, and  
ed herself at Florence to the education  
of 3 children, and at the same time estab-  
l a free singing school for girls, on  
tion that they should adopt, in addition  
their own name, that of Catalani. In June,  
during the revolution in Tuscany, she  
to Paris with her daughters, but almost  
mediately after her arrival she fell a victim  
to cholera. Her favorite airs in concert were  
"Lacida Campagna," "the English anthem,"  
the violin variations of Rode. Whatever

exceptions may have been taken to her un-  
sympathetic singing, and although the fact of  
her premature exercise of her profession, before  
she had fully mastered all its scientific details,  
was frequently apparent in her execution of  
long pieces, there was only one opinion as to  
the immense volume and the inexhaustible  
elasticity of her voice, the brilliancy and power  
of which was never surpassed. She left to her  
children a fortune of \$1,600,000.

CATALEPSY (Gr. *καταληψις*, seizure), a  
non-febrile affection, occurring in paroxysms,  
and characterized by a sudden deprivation of  
intelligence, sensation, and voluntary motion.  
The disease is so seldom met with that some  
well-known writers have doubted its existence,  
and have attributed the recorded cases to im-  
posture. Bourdin (*Traité de la catalepsie*, Paris,  
1841), who collected all the recorded facts  
within his reach, was able to unite but 88 well-  
characterized observations. The attack is often  
preceded by headache, confusion of mind, loss  
of memory, &c.; more commonly, however,  
nothing of the kind has been noticed. During  
the paroxysm the patient retains the position  
and expression of countenance he had at the  
moment of the seizure; the face is commonly  
pale, sometimes slightly flushed; the pupils are  
dilated; but contract on exposure to a strong  
light; the limbs can be moved with the exer-  
tion of a little force, and retain the new position  
which may be given them; if the patient is  
standing and is pushed, he makes no effort to  
save himself; if placed in a painful and con-  
strained attitude, it is retained during the par-  
oxysm. The unvarying, motionless attitude  
and fixed expression give a strange and corpse-  
like look to the sufferer. The duration of the  
attack is variable; sometimes it lasts but a few  
minutes, sometimes 12 or 14 hours; cases are  
recorded in which it has been prolonged to 20  
or even 80 days. Many cases occur in which  
the attack is less characteristically marked, or  
in which a portion only of the symptoms is pres-  
ent. Although deprived of speech and volun-  
tary motion, the patient is more or less conscious  
of what is passing around him. In Duncan's  
"Medical Commentaries," a case is related of a  
woman who in this state of partial catalepsy  
was taken for dead, and who was perfectly con-  
scious of what was occurring around her, while  
her body was being laid out and prepared for  
interment. In ecstasy, a disease allied to cata-  
lepsy, and which by imperceptible degrees  
passes into it, the patient is insensible to every  
thing about him, while the mind is absorbed in  
some one object or train of ideas; the muscles  
are either relaxed or in a state of almost tetanic  
rigidity, while the patient speaks and sings, per-  
haps with greater readiness and ease than in  
his natural condition. This condition is fre-  
quently occasioned in nervous and hysterical  
persons by religious excitement, and is often  
produced in a similar class of persons by animal  
magnetism. It is one much more commonly  
assumed by impostors than true catalepsy. Both

cataplexy and ecstasy seem to be closely allied to hysteria; they occur for the most part in young females of nervous habit, and both the one and the other often commence or terminate in it; occasionally, however, as is likewise the case with some of the more ordinary manifestations of hysteria, they have their origin in serious disease of the brain. The age and history of the patient will help the intelligent physician to discriminate such cases. Some strong moral excitement is generally the immediate cause of the disease, but when it is already formed, or when the predisposition to it is very strong, a most trifling cause—a sudden noise, the surprise of an unexpected visit, &c.—may induce a paroxysm. In itself the disease is never fatal, and morbid anatomy throws no light upon it. In regard to the treatment, in the interval between the paroxysms means should be employed to improve the general health and give tone to the nervous system. During the paroxysm the feet may be immersed in a mustard foot bath and cold applications made to the head; of these, where it can be borne, the cold douche is the most effectual.

**CATALOGUE** (Gr. *καταλογος*, from *κατα-λεγω*, to enumerate), a list or serial registry of a collection of similar objects, as books, paintings, medals, plants, shells, or minerals. The term is most frequently applied to books, signifying an enumeration of the volumes contained in a library, disposed in a certain order. The arrangement may be in the alphabetical order of the titles of books, in the alphabetical order of the names of authors, or in a systematic order according to the subjects treated in the works. Of alphabetical catalogues there are 2 especially remarkable for the results of erudition which they contain, that of the Bodleian library in the university of Oxford, and that of the library which Cardinal Casanato bequeathed, in 1770, to the Dominicans of the Minerva at Rome. The former, which has been several times republished and enlarged, abounds in references to the various editions of old authors. The latter mentions the birth, country, and death of the authors, gives references to sources of information concerning them, and indicates those works which form part of great collections. Four volumes of this catalogue, extending to the letter I, were published between 1761 and 1788, under the editorial care of Audiffredi; but the work was undertaken upon so vast a plan that it has not been completed. The catalogue of the library of the British museum, now in process of preparation, is arranged alphabetically, and the letter A alone embraces 16 volumes. Ordinarily, an alphabetical catalogue is only an index to a library; but a catalogue arranged in the order of the contents of books, has the additional advantage of showing the amount of literary labor which has been done in the different departments of learning and taste. When arranged alphabetically by the order of the authors, a catalogue may have something of a

biographical interest, but when systematically by the order in which the subjects are treated, it has a more extensive utility. In joining to the alphabetical table of authors an alphabetical table of the subjects of the works, the chief utility of all are combined, and the highest degree of utility. A copy the arrangement of a catalogue in a different order. One of the first proposed for cataloguing the library of the British museum was to make the catalogue out of a list of title pages put out in any order, but accompanied by alphabetical indexes, one of subjects, the other of authors. The old form a universal catalogue, *Universalis* of Conrad C. Zürich in 1545-'48, which contained of all the books then known in Hebrew and Latin, with frequent references to the contents, judgments upon the merits, and even specimens of their style.—Various systems of literature have been proposed for the classification of books. The French librarian, Naudé, in a catalogue published in 1643, established 12 departments: bibliography, chronology, geography, biography, the military art, civil law, philosophy, politics, and literature. In 1678, Garnier, the librarian of the Louis XIV., reduced these to 4: theology, philosophy, history, and law or jurisprudence. Early in the 18th century the bibliographer Martin arranged the departments of theology, jurisprudence and sciences, belles-lettres, and arts. These have since been usually observed in alphabetical catalogues and bibliographical systems. Haym, in his *Bibliotheca Italica*, published in London in 1726, made 4 great departments: history, poetry, prose, and the sciences. The learned Morelli, in his catalogue of the library of St. Mark of Venice, published in 1763, divided the MSS. into 20 departments. Casiri, in his catalogue of the Arabic MSS. contained in the library of the Vatican, distributes them in the following order, which is similar to that adopted for the MSS. in the same library: grammar, rhetoric, philology and miscellanea, lexicons, politics, medicine, natural history, jurisprudence, theology, geography, and history. Many followed for a long time the alphabetical arrangement of Fabricius, who published a catalogue, in 6 volumes, of the MSS. of the Vatican. This work contains notices concerning the MSS., the editors, and commentators, the MSS. themselves, criticisms, or apologetics concerning the contents, and anonymous or doubtful MSS. The regularity in the arrangement, which the work supplies, is a methodical and detailed bibliography that has ever been

Librarian of the university of Jena, contained in his "General Repertory of Literature," which appeared in 1790. In this scheme there are 16 leading divisions: general literature, philology, theology, jurisprudence, medicine, philosophy, pedagogy, science of state, science of war, knowledge of nature, knowledge of the arts and trades, mathematics, geography and history, the fine arts, literary history, and miscellanea. Denis, an officer in the imperial library of Vienna, in an "Introduction to the Knowledge of Books," the 2d edition of which appeared in 1796, explains a bibliographical system which, according to him, would form a complete encyclopædia. It is composed of 7 principal parts: theology, jurisprudence, philosophy, medicine, mathematics, history, and philology. In England the attempt has often been made to adopt in cataloguing the genealogical tree of human knowledge furnished by Lord Bacon. Yet experience has proved that there is a striking difference between the classification of the branches of learning, and that of the books in which learning is contained. Books are so much more various and manifold than the human faculties, that a valuable bibliographical system must always be the fruit of experience rather than a product of genius. All the attempts that have been made to establish bibliographical divisions upon metaphysical principles have been fruitless. Conyers Middleton in 1723 published a method for arranging the library of Cambridge, which, although it recognizes 9 departments instead of 5, has a close affinity with the method prevalent in France. The catalogues which have since been published by the best English librarians are usually divided into 6 classes: miscellaneous literature; theology and ecclesiastical history; laws and jurisprudence; medicine, surgery, physiology, and chemistry; works in Hebrew, Arabic, Greek, Latin, &c.; and educational works.—Among catalogues remarkable for the large number of books which they mention are the *Bibliotheca Thottiana*, 12 vols., Copenhagen, 1789-'95; *Catalogue du Duc de la Vallière*, 9 vols., Paris, 1783-'88; and the *Bibliotheca Heberiana*, 9 vols., London, 1834-'36. The *Catalogus Bibliothecæ Harleianæ*, by Maittaire, 5 vols., London, 1743-'45, the "Catalogue of the Roxburgh Library," London, 1812, Clement's *Bibliothèque curieuse*, 9 vols., Göttingen et Leipsic, 1750-'60, and Dibdin's *Bibliotheca Spenceriana*, 4 vols., London, 1814-'15, are especially valuable for their mention of rare and costly books and old editions. Important with reference to Hungarian history is the catalogue of the library of Count Széchényi, Oedenburg, 1791; to classical literature, that of Count Rewiczki, Berlin, 1794; to Italian literature, those of Capponi, Rome, 1747, of Ginguené, Paris, 1817, and of Libri, Paris, 1847; to the fugitive writings during the period of the French revolution, that of Pixérécourt, Paris, 1838; to French dramatic literature, the *Bibliothèque*

*dramatique* of Soleinne, Paris, 1843, *et seq.*; and to oriental literature, the catalogues of the libraries of Langlès, Paris, 1825, and of Sylvestre de Sacy, 8 vols., Paris, 1842-'45. The "Construction of Catalogues of Libraries," by C. O. Jewett, the second edition of which was published at Washington in 1853, contains many valuable rules and suggestions.

CATALONIA (Sp. *Cataluña*), an ancient division of Spain, lying between lat. 40° 30' and 42° 51' N., and long. 0° 15' and 3° 21' E. Area 12,180 sq. m. Pop. 1,250,000. It is bounded on the N. by the Pyrénées, E. by the Mediterranean, S. by Valencia, and W. by Aragon. Catalonia is now divided into 4 provinces, viz.: Barcelona, Tarragona, Lerida, and Gerona. The face of the country is much broken by spurs of the Pyrénées. Some of these mountain ranges diverge toward the Mediterranean; others, of which the chief is the Sierra de la Llena, pursue a S. W. direction to the Ebro, and form a water-shed in which 26 rivers have their rise, and flow either westward to the Ebro, or eastward to the sea. The principal of these streams are the Segre, a tributary of the Ebro, the Noguera Pallaresa and Noguera Rivagoranzo, tributaries of the Segre, the Llobregat, Francoli, Tordera, Ter, Flavia, and others. None of these are navigable to any great extent. The general grade of the country is a descent from the mountain altitudes of the Pyrénées to the plateaus of upper Catalonia, and thence to the plains which skirt the Mediterranean. Most of the inland mountains are of granitic formation, those near the coast are limestone. Traces of volcanic origin are found especially in the vicinity of Barcelona. Valleys of remarkable fertility intersect the mountains. Such are the plateau of Urgel, and the valleys of Cerdagne, Tarragona, Vallez, La Selva, Igualada, Cervera, Ampurdan, and Lerida. About  $\frac{1}{4}$  the surface of the province is susceptible of cultivation, the rest consisting of rocks, barrens, and woodlands. Forests of beech, pine, elm, oak, and cork are found in the mountainous districts. Minerals abound. Iron, copper, lead, and manganese are found. Coal is met with in quantity, but it has been turned to little account. Of alum, nitre, and rock salt, the supplies are inexhaustible. At Cardona is a mound of pure salt, 500 feet in height and 3 miles in circumference. Other geological peculiarities are observable. Near Olot, 55 m. N. from Barcelona, is a remarkable district of extinct volcanoes. Montserrat is a single and precipitous mountain, composed of a number of conical hills heaped in confusion one over another, and broken into fantastic shapes of parti-colored limestone. A Benedictine monastery is perched on the cleft of a hill. Mineral and hot springs are found in various districts, as are crystals, amethysts, topaz, jasper, and marbles. The climate of Catalonia varies with the altitude of the region, but is in general temperate, the heat being moderated by sea or mountain breezes. The country is con-

dates at the "critical period," or "change of life;" including a period of some 30 years, between the ages of 14 and 45. The blood of

menstrual flux is exuded from the vessels of the uterus, and escapes through the vagina;

which generally returns every 28 days, and continues from 3 to 6 days. The amount discharged varies from 4 to 8 oz. in most cases, and every woman is a law unto herself in this respect; as that which would be merely normal in some women would be profuse in others.

The first menstrual flow is generally preceded by languor, pains in the back, head, chilliness, &c., which usually disappear when the discharge takes place. The after effects are often unaccompanied in healthy women by any premonitory or attendant symptoms.

During the whole of a woman's life she is capable of bearing children. When the uterus is closed, she ceases child-bearing.—

The influence of climate in advancing or retarding the period of puberty and menstruation, has been shown by recent observation to have been formerly much over-rated, the average age being much the same all over the world, and the occasional cases as numerous in one region as in another.

Mr. Robertson has shown, from medical evidence, that menstruation does not commence more early in the negress than in the white female, and Dr. Vaigas affirms that premature menstruation is more common in the white than in the colored races. Early marriages in Hindostan and other warm climates, then, do not depend on natural precocity, but on the customs and habits of the country.—The uterus becomes congested during menstruation, and so are the Fallopian tubes; the tissues of the vagina are relaxed, and the *os uteri* is enlarged and swollen; these conditions disappear when the flow ceases, and the parts return to their natural state. During pregnancy and lactation, the menses usually cease, and they may also be suppressed from other local causes.

Various means of obviating the ill effects of suppressed menstruation, by substituting a similar discharge from some other part. It occurs in the gums, the nostrils, the lungs, the skin, or even from the eyes, and other parts of the body.

CATAMOUNT. See COUGAR.

CATANDUANES, an island of the Philippine group, S. E. of Luzon, lat. 13° 47' N., long. 124° 10' E., is 36 m. long from N. to S., and averages 19 m. wide. The inhabitants are a primitive race, and live by agriculture, fishing, and the construction of a light species of canoe, which they sell to the adjacent islanders.

CATANIA (anc. *Catana*), a seaport city of Sicily, and capital of the province of the same name, situated on the E. coast of the island, on the shore of the gulf of Catania, which is an arm of the Mediterranean, at the foot of Mount Etna.

Area of the province, 1,761 sq. m. In 1856, 411,832; pop. of the city about 100,000. It is esteemed the handsomest city

in Sicily, with wide and regular streets, and numerous and splendid public buildings. Its vicinity to Etna has introduced the use of lava for various purposes. The streets are paved with it, the finest buildings made of it, and it is formed also into ornamental chimney-pieces, tables, and toys.—The ancient Catana suffered severely in the Roman wars. The modern city has been several times nearly destroyed by earthquakes and eruptions of Etna, but has been rebuilt each time with greater beauty than before. It has many remains of the Roman city, among which are an amphitheatre, a theatre, and ruins of baths and temples. Its principal public edifices are the cathedral, rebuilt since the earthquake of 1693, the senate house, the university building, frequented by about 500 students, and a vast Benedictine convent. The city gives title to a bishop, has an upper tribunal, and a board of trade. The surrounding country is famous for its excellent wine, and also for its corn. The annual production of wheat is about 400,000 qrs., of which 300,000 are used for home consumption, and the rest for exportation. The production of olive oil is also considerable; and of lemons and oranges about 100,000 boxes are exported annually. The other principal articles of trade are almonds, figs, hemp, flax, soda, manna, cheese, macaroni, amber, cantharides, lava, and snow from Etna, which is exported to Malta. Among the manufactures must be mentioned those of linen and silk; the carvings of amber, lava, marble, and wood, wax bleacheries, and distilleries of licorice and oil. The port of Catania ranks as the third port in Sicily, the annual entrances and clearances of vessels amounting collectively to about 2,000, and carrying cargo to the value of \$500,000. Next to Messina, Catania is the chief mart for silk, the united exports of both cities amounting annually to about 450,000 lbs., beside the silks retained for the local manufactories. In 1848 and 1849 Catania was disturbed by violent popular outbreaks, especially on April 6 of the latter year, when the Neapolitans expelled the Sicilians from the city.

CATANZARO, a town of Naples, capital of the province of Calabria Ultra, situated on a mountain near the gulf of Squillace, 30 m. S. S. E. from Cosenza; pop. 12,000. It suffered severely from an earthquake in 1783, which overthrew some of the principal buildings. It still has, however, a cathedral, several churches and convents, a castle, a royal academy of sciences, and numerous schools and charitable institutions. Considerable trade is carried on in cattle, corn, and wine, and there are manufactures of silk and velvet. The women are reputed the handsomest in Calabria.

CATAPHRAOT (Gr. *καταφρακτος*, mailed), in ancient military art, a horseman in complete armor. The cataphracts were heavy-armed cavalry, the horses of which were also covered with defensive armor, with scales or plates of metal.

**CATAPLASM** (Gr. *καταπλάσμα*, from *κατα-πλάσσω*, to spread over, to plaster), a poultice, or soft substance applied externally to some part of the body, either to repress inflammation and allay pain, or to promote inflammation or its consequences, and lessen the pain attending it. For the former purpose it is applied cold, and often contains a preparation of lead to increase its astringent and refrigerating power; for the latter, it is used at different degrees of temperature. When intended to hasten the progress of inflammation and lead to suppuration, poultices should be of as high a temperature as the part will bear; but of a lower temperature when used as mere emollients. Cotton-wool, steeped in water, and bound to the part with a light bandage, is a very simple and efficient application, in most cases where a cold poultice is required to allay pain, and repress inflammation.

**CATAPULT** (Gr. *κατα*, against, and *παλλω*, to hurl), an ancient military engine for throwing stones, darts, and other missiles, invented in Syracuse, in the reign of Dionysius the elder. It acted upon the principle of the bow, and consisted of wood frame-work, a part of which was elastic, and furnished with tense cords of hair or muscle. Catapults were of various sizes, being designed either for field-service or bombardments. The largest of them projected beams 6 feet long and weighing 60 lbs. to the distance of 400 paces, and Josephus gives instances of their throwing great stones to the distance of  $\frac{1}{4}$  of a mile. The Romans employed 300 of them at the siege of Jerusalem. From the time of Julius Cæsar it is not distinguished by Latin authors from the *ballista*, which was originally used only for throwing masses of stone.

**CATARACT**, a disease of the eye in which there is an opacity of the crystalline lens or of its capsular investment. It is most common in old persons, in whom it seems to be the natural consequent of age; but it also occurs in infants, and is even congenital; it appears to be more frequent in cold and damp climates than in warmer regions, and it is certainly hereditary in many instances. Among the exciting causes, especially of the capsular form, are wounds and inflammations of the internal eye; but the ordinary cause is the diminished nutrition of the organ in common with others in advancing age. True cataract may be either lenticular, capsular, or capsulo-lenticular, according as the seat of the opacity is in the lens itself, in its capsule, or in both at the same time. Certain cases of opacity external to the crystalline apparatus have been called false cataracts, and may be caused by the effusion of lymph, blood, or pus, or by false membranes; secondary cataracts are those which follow the surgical operations for the extraction or depression of the lens. The lenticular cataract may vary in hardness from stony to gelatinous; its opacity is rarely uniform, being generally thickest in the centre and thinnest on the edges; in some cases the opacity begins at the circumference

in rays which slowly converge to the color varies from pearly white to yellow. The capsular cataract, which is considered more common than the lenticular, offers a great variety of colors, and may occupy either the anterior or posterior surface, or both. In the capsular form both the lens and its capsule are affected; the varieties common to both are: 1, the sign of cataract is a more or less white appearance behind the pupil of a white color, deepest in the centre, and becoming distinct as the disease progresses; 2, the sign is a gradual diminution of vision, accompanied by the sensation as if a cloud, spiders' webs, or snow-flakes, were before the eyes; objects are seen best in certain positions of the head, as when the head is turned to one side, and during the evening or at night, when the shade when the dilated iris permits light to enter the pupil; on looking at a flame appears surrounded by a thick white haze. The progress of the disease is very generally unaccompanied by fever, pain, or disturbance of the general health. It is rare for a person to be unable to see day from night. M. Sanson has proposed an excellent catoptric test for the detection of cataract by the reflection of light. A lighted candle is held before the eye of a healthy person, 3 images of it are seen: 1, erect, moving upward when the eye is moved upward, produced by reflection from the cornea; 2, also erect, produced by reflection from the anterior surface of the capsule, and moving upward with the eye; 3, very small and inverted, produced by reflection from the posterior surface of the capsule. In the case of cataract, the inverted image is first beginning indistinct, and soon disappears; the deep, erect one is also soon visible. By dilating the pupil with opium this experiment is rendered easy. Cataract is for the most part removable by a surgical operation; certain cases, however, arising from inflammation of the capsule, with the exciting cause without removal, and cases are on record of the removal of lenticular cataract by the rupture of the capsule and the escape of the lens into the anterior chamber of the eye, where it is usually dissolved.—From the earliest times surgeons have attempted to destroy cataracts by means of needles and knives of various forms. Whenever the disease is confined to the lens and its capsule, and the eye respects is healthy, and the patient is young or too old, an operation is attended with a prospect of success; but in persons under 20 years of age, it is better to be operated on at once, and the chance of a successful result is small. Before submitting to an operation, it is well to prepare the patient with a mild diet and a gelatinous food.

any inflammatory tendency of the organ; and then to smear belladonna ointment around the orbit, or to put a few drops of its fluid extract into the eye, for the purpose of dilating the pupil to its utmost extent. All operations for cataract reduce themselves to 3, which have for their object either to displace the lens, to break it up, or to remove it from the eye: 1. Operation for depression of the lens, or couching. The description of this may be found even as far back as Celsus; it has undergone many modifications in modern times. The instrument employed is a fine needle, either slightly curved at the end or straight, with the point spear-shaped; Scarpa's needle is slightly curved at the end. When the needle is passed through the sclerotic, as ordinarily, the operation is called *scleroticonyx*; when it is passed through the cornea, *keratonyxis*. Different needles are preferred by different operators; but, as in the case of the stethoscope, that instrument is the best which the surgeon is accustomed to. In *scleroticonyx* the needle, held like a pen, is passed through the sclerotic, perpendicularly to its surface, a line or two from the cornea and a little below its transverse diameter; the concavity of the instrument is turned down, in order to separate rather than to divide the fibres of the membrane; when the needle is fairly in, its concavity is turned backward, so that it may pass under and before the lens without touching the iris or the capsule; when it has reached as far as the pupil, the capsule is lacerated by delicate circular movements of the point; then the needle is applied directly to the lens, which is pushed outward and backward to the bottom of the globe, out of the line of the axis of vision; it is held there a short time, that the cells of the vitreous humor, into which it is pushed, may resume their position around it, and thus prevent its reascension in the line of the pupil. Some surgeons prefer the operation by reclinacion, which consists in turning the lens backward from an upright to a horizontal position; and some always recline the lens before they depress it. In *keratonyxis*, the needle is passed through the cornea, about  $\frac{1}{4}$  of an inch from the sclerotic, on its lower and exterior portion, and is directed through the dilated pupil to the lens, whose capsule it is made to lacerate; and, if possible, the lens is depressed, reclined, or broken up. This method is objectionable on account of the danger of wounding the iris, and of the difficulty of reaching the lens, and is applicable only to exceptional cases. After the operation, the eye should be lightly covered, and the patient should remain in bed in a darkened room, with the head raised, and be kept on a low diet for a few days; after 4 or 5 days in ordinary cases, a little light may be gradually let into the room, and at the end of 3 weeks the eye may be generally left uncovered. The accidents most to be feared are inflammation of the iris, choroid coat, and retina, which should be treated by antiphlogistic measures.

2. The operation for breaking up the lens, without depressing it, is very easily performed, and excites very little inflammation; but it requires frequent repetition, is slow in its progress, and is adapted only to soft and especially to congenital cataracts. The needle is inserted just as in the method for depression, the capsule is divided, and the lens is freely broken up without removing it from its place; the cataract is thus brought into contact with the aqueous humor, and is gradually dissolved by it. 3. In the operation for extraction, the cornea is incised through rather more than half its circumference, the capsule is lacerated, and the lens is extracted from the eye entire; it is performed with a triangular knife, with sharp point, straight and blunt back, the edge slanting obliquely, and the blade growing wider and thicker as it approaches the handle; this kind of knife cuts by the simple motion of pushing, and fills up the incision as it makes it, thereby preventing the escape of the aqueous humor. The cornea may be cut on its inferior or superior half, or obliquely on its external and lower portion, each of which has its special advocates. When the lower half is cut, the knife, with its edge downward and forward, is passed into the external side of the cornea, perpendicular to its axis, a little above its transverse diameter, and about a line from the sclerotic; passing in front of the iris, the point is made to cut its way out on the inner opposite surface; the cutting of this flap constitutes the first period of the operation, after which the lids are permitted to be closed for a few seconds. Taking care in the subsequent steps of the operation not to make pressure upon the globe, the surgeon raises the flap, and, by means of a proper needle, lacerates extensively the capsule; if, at this time, the lens does not of itself come forward into the anterior chamber, gentle and properly directed pressure will cause it to come out; to complete the operation, it is sometimes necessary to remove also the pieces of the divided capsule. When the lower half of the cornea is opaque or in a condition unfavorable to cicatrization, or very small, Wenzel, Richter, and Jäger recommend the section of the upper half; the steps of the operation are about the same, though perhaps more difficult to execute; it offers the advantages of presenting less liability of the iris being wounded, of the vitreous humor escaping, and of the lips of the section being separated by the edges of the lids. By the oblique incision, which is the favorite in France, the lids could not possibly interfere with the apposition of the edges of the wound. More care is required after extraction than after depression, to avoid inflammation; after it is certain that the patient can distinguish objects, the eye is lightly covered and the person confined to bed in a dark room, with the head but slightly elevated.—Of these operations, extraction removes with certainty the obstructing lens, is very little painful, does not wound the ciliary vessels or nerves, the choroid, or the retina; but it may cause deformity of the pupil or the escape

of the vitreous humor; the edges of the wound may not readily heal, or may ulcerate, with hernia of the iris or opacity of the cornea. Depression leaves a permanent cause of irritation in the eye, and the lens is liable to reascend; the needle perforates the choroid and retina, and may cause inflammation of the internal eye; but there is no danger of the escape of the vitreous humor, nor of spots or ulcers of the cornea, nor of hernia of the iris, nor of immediate evacuation of the globe. Depression is best in children and intractable persons; where the eyes are small and deep-seated, the cornea flat, or the conjunctiva irritated. When the cataract is soft and the pupil small or adherent, extraction is best in old persons; in adults with a large anterior chamber and the eyes sound; and when the cataract is hard or membranous. Convex spectacles are necessary, under proper restrictions, to supply the place of the extracted crystalline lens.

**CATARACT**, the sudden fall of a large body of water over a precipice. The term *cascade* is applied to a smaller body of water falling from a great height. Rapids are formed by the impetuous flow of water down an inclined plane and over rocks. The American rivers furnish sublime waterfalls, especially those formed by the currents issuing from great lakes. The waters of Lake Superior at its very outlet form the falls of St. Mary (Sault Ste. Marie). A river a mile wide descends in a rapid current 22 feet within  $\frac{1}{4}$  of a mile. A body of water, apparently as large as that which flows over the precipice of Niagara, rushes unceasingly from the great reservoir above, whirling and foaming among the rocks, and presenting an impassable barrier to all modes of navigation except the frail barks of the Indian and French voyageurs. Among the whirlpools and eddies of these falls the birch canoe glides like an arrow past the threatening rocks the least touch of which would rend it in pieces. Its course is controlled and directed by the steady and strong arm of the Indian giving to it a greater speed than that of the waters upon which it is borne. The falls are lost below in the smooth waters of St. Mary's strait, and thence these pass tranquilly on through the great basins of Lakes Huron and Erie, till in the Niagara river they again rush impetuously down the rapids which lead to the great cataract. This is the most famous in the world, being the largest body of water precipitated from so great a height. The fall on the British side is 150 feet, on the American 164 feet. (See **NIAGARA**.) Following the course of these waters through Lake Ontario, their next sudden descent is in the St. Lawrence river, where in a distance of about 9 miles above Montreal occur a succession of remarkable rapids, known by the names Coteau du Lac, the Cedars, Split Rock, and the Cascades. In consequence of the great depth of the water, these rapids are safely navigated by steamboats descending the river, their course being controlled, as is that of the birch canoe, by giving to them

additional speed. The most remarkable cascade is the stream 6 m. N. E. of the falls, among the Catskill Mountains, New York, are celebrated for their beauty. The cascades are supposed to be small lakes, the waters of which, after passing into a deep ravine, whose precipitous sides are from 1,000 to 1,500 feet high, are precipitated. (See **CATSKILL MOUNTAINS**.) Niagara is met with in California, where it is described in the article **CALIFORNIA**. In the American continent, the falls of Niagara are the most prominent. They form the descent of the river Funza from the plain of Santa Fé de Bogota. The height of the falls is 574 feet, and the column of water that rises from them is visible at the distance of 17 miles. (See **BOGOTA**.) Among the waterfalls of Europe, that at Trollhætta, in Sweden, is as the highest for the body of water. They occur frequently, though usually of small size, and dependent for their interest upon the wildness of the surrounding scenery, the dark and rocky glens through which they rush. The cascades in the Alps are among the highest in the world. The most remarkable are the Evanson, which has a height of upward of 1,200 feet, and the Rhodan, which has a vertical fall of 2,400 feet. They are, or more properly the rapids, of the Nile are celebrated.

**CATARRH**, a non-inflammatory affection characterized by an increased secretion of mucus from the glands of the mucous membrane; the name is popularly confined to the membrane of the air-passages, but may be extended to that of the stomach, intestines, and even genital mucous membranes. At the time of Hippocrates, the term was applied to the secretion of catarrh from the eye, whence it might easily be supposed to have descended into the ear, nose, and throat; and some modern empirics have adopted a similar idea as their own. A tradition was that a part of the mucus, rising in vapor to the brain, and passing through the arch of the skull, as in the case of the nose, and reappeared in this fluid secretion: a favorite theory of Galen. At the time of Van Helmont, and later of Schneider, in the middle of the 18th century, it was held that the fluid of catarrh was secreted by the glands of the nose. Though a local affection, it may be maintained, of many of the diseases observed by him in the nose of children and adults of the low country are most subject to it; frequently in colds, and accompanied by sudden changes in individuals we observe it by the foul air, and mentally. Catarrh

stitutional disturbance; the principal symptoms are sneezing, increased secretion of mucus, and a snuffling nasal respiration; it is in the head; in this form, or in infants, there may be feverish symptoms, considerable difficulty of breathing, interfering with the act of sucking; in older persons the eruptive diseases most commonly begin with *coryza*. If in the throat, there is wheezing respiration, huskiness or hoarseness of the voice, and a sense of fulness or swelling of the membrane. When the disease extends to the lungs, it may easily pass into an inflammatory bronchitis, or pneumonia, arising from the mere accumulation of mucus; but it more commonly, especially in old persons, takes on the form of chronic catarrh, with a very profuse secretion of frothy matter, requiring great effort of expectoration. In like manner the stomach is affected in old age, giving rise to hæmorrhæa, without inflammation, characterized by vomiting of mucous matter resembling white of an egg, and seriously interfering with the digestive process. So, many diarrhoea consist essentially in a catarrh of the intestinal mucous membrane, with an increased secretion of the muciparous glands of the canal. In many cases of catarrh of the bladder the urine is loaded with mucus, and the membrane highly irritable, without being positively inflamed. Catarrhal diseases often occur epidemically, under the name of catarrhal fevers, in which there seems to be a morbid disposition in all the mucous membranes to secrete an excess of mucus. Under the conditions already mentioned, the mucous membrane may be affected, giving rise to some forms of *leucorrhœa* and *rhœa*; the conjunctiva may also be affected, giving rise to catarrhal ophthalmia; and these conditions, especially the last two, are sometimes contagious, without the usual specificity. These catarrhal diseases are not very dangerous; but they are apt to become chronic and exceedingly difficult to remove when the lungs, stomach, intestines, and urinary organs are affected, and especially when occurring, as they often do, in old debilitated persons. The treatment of the disease is entirely expectant; in the chronic form the principal dependence is on tonics and stimulants, especially quinine, and on local applications of a stimulating and alterative character whenever the seat of the disease is accessible. They form some of the most obstinate cases the physician has to manage, from the difficulty of direct medication, and from the age and weakness of the majority of persons who suffer from them.

**CATAWBA**, a new and thriving post town of Lehigh co., Pa., pop. 1,500, on the west bank of the Lehigh river, 3 m. above Pottsville, contains a number of churches, 4 or 5, and is well supplied with water by a series of waterworks. The Crane iron works,

said to be the largest smelting establishment in the United States, are situated here. One of the furnaces has turned out in a single week the extraordinary amount of 285 tons of iron.

**CATASTROPHE** (Gr. *καταστροφή*, revolution), the change or revolution which takes place in and terminates a dramatic action. The ancient drama was divided into the protasis, epitasis, catastasis, and catastrophe, or the introduction, continuance, heightening, and development or conclusion. The plot being laid in the preceding parts, and raised to the highest degree of intricacy and portentousness in the catastasis, it became the most difficult task for the dramatic poet to produce properly the catastrophe; to introduce it as something long expected and foreseen, or as something disappointing all expectation, and essentially untrue and incredible. To produce the latter kind of catastrophe, the Greeks sometimes made use of the *deus ex machina*, a divine agency suddenly introduced to cut the knot which the poet could not untie. In modern tragedies and higher comedies, the catastrophe is often placed in the inward development of character, and is produced necessarily, like the working out of a cause, from a series of preceding situations. The difficulty of devising catastrophes which shall be at the same time natural and exciting, is seen in the numerous dramas which abound in striking situations, but which have neither æsthetic nor psychological significance.

**CATAWBA**, a co. in the W. central part of North Carolina; area 250 sq. m.; pop. 8,862, of whom 1,569 are slaves. It derives its name from the Great Catawba river, which forms its N. and E. boundaries. The surface is diversified, the soil fertile, and drained by the S. Catawba river. Its productions in 1850 were 52,190 bushels of wheat, 65,674 of oats, 855,185 of Indian corn, and 6,086 lbs. of tobacco. There were 2 iron founderies and one tannery. Iron ore is abundant. This co. was formed from the N. part of Lincoln in 1842. Capital, Newton.

**CATAWBA**, or **GREAT CATAWBA**, a river of N. and S. Carolina. It rises in the Blue Ridge, in Burke co. of the former state, flows nearly E. through the gold region of N. C., makes a bend to the S. at the W. border of Iredell co., and enters S. C. near the mouth of the Little Catawba, about 15 m. from Yorkville. After reaching Rocky Mount in this state, it takes the name of the Wateree, and ultimately unites with the Congaree to form the Santee. The length of the Catawba is about 250 m.; of the Wateree, 100 m.

**CATAWBA WINE**. The Catawba grape was first discovered in a wild condition about 1801, near Asheville, Buncombe co., N. C., near the head waters of the Catawba river. About a quarter of a century afterward the grape was found by Major Adlum, in a garden of a German near Washington, Gen. Davy, of Rocky Mount, on the Catawba river, having been the supposed original transmitter of a few plants to that city during the period of his

senatorship, some time previous to 1816. Major Adlum wrote, before his death, to Mr. Longworth, of Cincinnati, who procured some of the Washington grapes, and who was the first to experiment with them on a large scale: "I have done my country a greater benefit in introducing this grape to public notice, than I would have done if I had paid the national debt." The wine produced by Major Adlum was sweet and agreeable, but sugar was added to the must. Mr. Longworth, however, abstained from any admixture of sugar or spirit, so as to produce the pure fermented juice of the grape. From Cincinnati the grape culture has spread along both banks of the Ohio to Pittsburg and Cairo, and in a southerly direction through Kentucky and Tennessee to Alabama, and westward into Missouri. The juice of the grape is manufactured either into still wine or sparkling wine; the latter, which is most in demand, containing an addition of alcohol. The wine is mostly white, though some red wine is made. A sample of Catawba, 7 years old, was proved to contain from 11 to 11½ per cent. of alcohol. According to the census of 1850, the total production of all kinds of wine in the United States was 221,249 gallons, showing an increase of 96,515 gallons over the production of 1840. But this increase, great as it was, dwindles into insignificance when compared with the rapid strides which the production has made within the last 8 years; the credit of pushing it to its utmost extent being especially due to the population of German birth or descent in the west and north-west. The annual yield in the Ohio valley alone averages now 500,000 gallons, and in the whole country it cannot fall much below 2,000,000 gallons, or, at 90 cents per gallon when new, below a value of \$1,800,000. Of the 500,000 gallons produced in the neighborhood of Cincinnati in 1856, 40,000 were made into sparkling wines, and the rest drunk in the pure and simple state. The sparkling Catawba of Mr. Longworth's cellar of 1848 was peculiarly celebrated for its flavor and purity. The wine-houses of Mr. Longworth in Cincinnati have been, for the last 9 years, under the direction of an accomplished wine chemist from Rheims. His mode of preparation is thus described: "In the spring following the pressing of the grapes, the wine, which has meanwhile undergone the vinous fermentation, by which 10 or 11 per cent. of alcohol is developed, is mixed with a small quantity of sugar, and put into strong bottles, with the corks well fastened by twine and wire. The sugar accelerates a second fermentation, which always takes place about this time, and thus a strong movement is produced inside the glass, which generates gas enough to burst the vessels briskly, adding thereby considerably to the cost. This is called the gaseous fermentation, and it renders the drink more exhilarating, more prickling on the tongue, and more fruity. This last effect results from this, that the flavor of the fruit

mostly passes off with which is largely gone fermentation, and in second or gaseous fermentation from the first fermentation but by means of corks, it can be saved in end of about a year, and a sediment has been of this sediment, the made to fit their necks with corks downward, and several weeks, which procement down against the cork twine are then cut, and the it off. Then more sugar, a new cork is driven in and few weeks the article is ready for consumption. Among the many other distinguished of the Catawba in Cincinnati, must be Mr. Robert Buchanan, who has written a book on the grape culture. a vineyard in the Ohio valley is at \$200 to \$500 per tend to 5 acres, and with and children several more beside raising the necessary of the family. The 500 gallons of wine per and from 600 to 900 such as 1848 and 1853.

CATBIRD (*mimus felices*, V of the thrush family, peculiar to ica. It receives this name from its note, which resembles the cat; this is not, however, morning and evening song of melody is worthy of the which it belongs. The cat Maine to Florida, the south toward the middle states about the April, and New England about one of the few species which of agriculture, being rarely in habitations of the farmer. is more slender and graceful American robin. Its plumage blended; the tail long and the bill is black, slightly color of the upper plumage slate color, the head, tail, and quills being of a brownish and general under plumage of gray, paler on the abdomen, coverts being brownish red; feather is transversely its inner web; the somewhat paler tint of wings 12 inches, The nest is large, generally thickets, and constructed of mixed with leaves, weeds, dark fibrous roots in manner. The eggs are of a greenish blue color,

ists of berries of the sweet-gum, poke, ch, insects, and fruits and berries of

It migrates during the night. It is y in its manners, and will follow with e for a considerable distance any in- its locality, mewing as it sits on a i its tail from side to side. It is ure, and hates especially cats and as attachment to its young is very le, and it will often feed and raise the other species. Beside its own agree- it possesses considerable imitative cking the notes of other birds in an manner; according to Latham, it will, a domesticated state, imitate strains ital music. Though this bird is persecuted, it deserves the kindest ; for its services to the agriculturist ing wasps, grubs, worms, and insects, ould have destroyed ten-fold more fruit than it ventures to claim at the maturity. Its flesh is good, but is d as an article of food.

I, a species of vocal composition of 8 parts, written in the same clef, the ace of which produces a very whimsi- humorous effect. The 2d voice com- he 1st part when the 1st voice has ed the 2d part, and the 3d voice com- he 1st part when the 2d voice has he 2d part, and the first voice the 3d e 1st voice then begins the 1st part ile the 2d voice takes the 3d part, and ice the 2d part, and so on indefinitely. is of English origin, and catch clubs, urpose of singing catches and glees, merly common in England; one of some celebrity, used to meet at the House tavern, in London, so far back

AU, LE, or CATEAU CAMBRÉSIS, a own, department of Nord, on the river m. from Cambrai; pop. 8,233. It is , has salt works, manufactories of meri- wls, calicoes, soap, and tobacco, and is producing a superior quality of linen Two treaties were signed there on April between England and the Netherlands e side, and France and Scotland on the ad on the following day between d Spain. Wellington made his head- there in 1815, and Marshal Mortier was e.

CHISM (Gr. *κατηχέω*, to sound back), in and modern sense, an elementary text- any science or art. More commonly, it means a text-book for the instruc- e catechumens and children of a par- ongregation in the doctrines of the r the moral precepts of Christianity. nal form of this instruction was oral, on and answer. The practice was to ose who needed instruction into some lace, and there persons qualified either utations, or delivered dogmatic lec- d then questioned the hearers upon

what had been said. It is probable that the early catechists followed no set forms, but en- deavored, by catechizing their hearers, to awaken a train of thought, and then followed it whither- soever it might lead. But when the doctrinal theology of the church became more strictly defined, catechetical instruction became more dogmatic. These compends have of course varied with the variations of theological opin- ion in different ages or communions. The council of Trent in 1545 drew up a form of doc- trine, which has been pretty closely followed since in the catechisms of the Roman Catholic church. Since that time, although the forms of the diocesan catechisms vary, there is a unanimity in their doctrine not found in Prot- estant churches. The principal catechisms of the Christian churches are the catechism of the council of Trent, which is a large and elaborate exposition, intended rather as a theological thesaurus for the clergy than as a system of popular instruction; the catechism of Luther (1529); of Calvin (1536); the Heidelberg cate- chism (1568), on the basis of which the Zürich catechism was drawn up (1639) for the Reform- ed church of Germany; the catechism of the Jesuits, drawn up by Father Canisius (1564); that of the Socinians, published at Racow (1574 and 1608); that of the English church, the work probably of Cranmer (1549), with the ex- ception of that part which relates to the sacra- ments, which was added by Bishop Overall in the 1st year of James I., after the conference of Hampton court; that of the Westminster assembly, longer and shorter (1643), which serves as a basis for the Calvinistic and Presby- terian churches, both of Great Britain and the United States; and finally, the catechism of Bossuet, which is in general use in the Roman Catholic church of France. There are many mediæval writings and documents bearing the name of catechisms which have recently been much studied, and which if collected together would form a work similar to the collections already made of old liturgies and hymns. The private or individual catechisms of German the- ologians are numerous, and many of them vo- luminous, departing from the primitive idea of the Christian catechism, as an instrument for popular and elementary instruction.

CATECHU, an extract of the inner wood of the *acacia catechu*, a small tree which grows abundantly in the East Indies. The drug had long been in use before its origin was dis- covered, and had been called *terra Japonica*, as it was erroneously supposed to be derived from Japan. It is prepared by cutting off the exterior wood, and boiling the dark-colored chips of the interior of the trunk in water. The solution is then evaporated to the consist- ence of sirup, when it is dried in the sun in the form of flat cakes, or moulded by pouring it into earthen vessels. There are 2 species of the catechu, one nearly black, the other red, both said to be the product of the same tree. There are other varieties, some of which prob-

ably never reach this country. That common in our markets is the preparation above described, and is imported from Calcutta. Catechu has no smell, but is bitter to the taste. It contains a large proportion of tannin, which is soluble in alcohol. It is employed in India for tanning hides, and also as a dye for cotton goods, and in Europe, in the calico print works. In medicine it is used as a tonic and astringent.

CATECHUMEN, a term applied originally to a person, adult or otherwise, who was under a preparatory course of instruction previous to admission to baptism. Catechumens had a particular place assigned them in the church, and were allowed to be present only during a part of the service; from the other part they were warned to retire, a deacon crying out, "Withdraw in peace, ye catechumens." Of catechumens, there were several degrees in the church. The private catechumens might only be privately instructed; the *audientes* might hear sermons; the *orantes* might take part in the prayers; the *competentes* were those who were ready to be baptized, and so stood at the threshold of communion. In later times, the term catechumens came to be applied to the children who were learning the catechism, as preparatory to confirmation.

CATEGORY (Gr. *κατηγορία*), originally, a charge or complaint made against any one, and hence it came to denote any thing that can be truly affirmed of a person or a thing; thus if we say A is B, B is a category of A, and A is in the category of B. The terms that may thus be predicated or affirmed may be classified in various ways and for various purposes; and the classes or genera into which they are divided are called categories. Of these Aristotle, the first writer that attempted a classification of them, made 10, namely: 1, substance or essence; 2, quantity; 3, quality; 4, relation; 5, place; 6, time; 7, position; 8, possession; 9, action; 10, passion. Thus if we are speaking of a man, we may give his substance or essence, a *man*; quantity, *one*; quality, *good*; relation, *friend*; place, *at home*; time, *yesterday*; position, *sitting down*; possession, *having a book*; action, *reading*; passion, *being tormented with the noise of children*. It is evident that in each of these cases the words in italics may be varied almost endlessly in the same category. Instead of man, the subject may be any thing else within the range of thought, and instead of 1 in the category of quantity there may be any number whatever; and the terms which are in the same category, as 1, 2, 5, &c., &c., are said to differ only in degree and not in kind. Thus all those in the category of quantity must denote some particular number, and those in the category of time must denote some particular time. It is evident from the passage in which this enumeration of the categories is given ("Topics," book i., chap. ix.), that Aristotle had in mind chiefly if not exclusively objects of sight or sense-perception, and classifies the predicates that might be affirmed

of them. The passage is as follows: "next define the genera of the categories which the above named four [that is, genus, property, and accident] are. Now these are 10 in number: quantity, quality, relation, where, when, position, possession, action, passion: for each of these, genus, and property and accident may be in one of these 10 categories. Propositions through these categories, as, a thing is, its quality or quantity, or its category. Moreover, it is evident that he who signifies what a thing is at signifies substance, at another signifies another some other category. For if substance is proposed, and one says that the proposed is man, or animal, he says what it signifies substance; but when where is proposed, and one says that the thing is white color, he says what it signifies quality. So, also, if when the time is proposed, one says that what is a cubit in size, he will say what it signifies quantity; and so of the rest of these, whether it be predicated of the thing, or if the definition of a thing be needed [that is, if its genus be affirmed or negated], signifies what the thing is. This it would seem that in the *Metaphysics* Stagirite all subjects as well as predicates may be referred to these 10 categories: there would be given to each a still wider comprehension than we have contemplated, and we should say that what we may speak of at all must be either quantity, quality, relation, place, time, possession, action, or passion; and the word category has passed from its original use as it did at first, literally, only to denote an affirmation of a subject, and to denote an enumeration or classification of the subjects themselves. In either sense of the word the classification is incomplete and inadequate. It has been found of much use, though the want of great service as a means of satisfying the want of some satisfactory classification has been constantly pressing upon the writers in this department. Considering predicates only (since for that was at first designed), the classification includes but very little of what we have to be said of a triangle, or any other mathematical figure, for example; still less of what should be said of a mere notion of intellectual activity, a fact of the mind, and still less of the attributes of other immaterial agent. And in the case of physical objects themselves, it would be to say to which of the categories they belong, our predicate would belong, or of the cause of any object. Or again, if we were to say to which of the categories the results of a chemical action belong, it would be difficult if not impossible to find one category within which to

of these difficulties, Kant proposed a classification of the categories. He seems to have thought that the result could be much more easily accomplished if we take for our starting point, not predicates as Aristotle did, but the fundamental laws and conditions under which cognition takes place; since it is only those properties, relations, and objects by means of which we have knowledge, that can be affirmed of it in any act of cognition. These categories (of the under-lying nature which Kant would regard them) he divided into 4 species with 3 varieties in each, making 12 categories in all. Kant thought this was the fundamental ground of Aristotle's error in his method, the *à posteriori*, and that if we succeed we must deduce the categories from the *à priori* forms of thought. These could best be found in the act of cognition, and from them he would derive the laws of judgment. Now of judgments there are 4 species with 3 varieties in each,

2. Quality.	3. Relation.	4. Modality.
(1) Affirmative.	(1) Categorical.	(1) Problematical.
(2) Negative.	(2) Hypothetical.	(2) Assertive.
(3) Indefinite.	(3) Disjunctive.	(3) Necessary.

In the opinion of Kant, there must be a certain condition of cognition for each variety of judgments, and consequently a variety or class of predicates for each: 1, as (1) one, (2) some, (3) all; 2, as (1) real, (2) unreal, (3) partly both, or real within certain limits; 3, as (1) substance and property or in-herency, (2) cause and effect or dependence, or reciprocal action (*Wechselwirkung*); and 4, as (1) possible or impossible, (2) being or not being, and (3) necessity and accident. Cousin has complained of this classification as unsatisfactory; and, in fact, it does not have answered any such purpose as was evidently expected of it. Cousin divides the primary classes of categories, as *à priori* according to Kant's notion, into two, the one called variously and under different conceptions of substance, cause, effect, &c., and the other under the terms property or phenomenon, relation or condition, &c. But this division seems to have lost sight of the object which Aristotle had in view, and was still a controlling motive with him, namely, some classification of predicates for the purpose of facilitating the processes of cognition, discussion, and reasoning. Dr. Whately, in his "Logic" (part ii. chap. 4), has divided predicates into 5 classes or categories: 1, *essentia*; 2, *differentia*; 3, *quantity*; 4, *quality*; and 5, *cause or effect*. He includes all the properties of the genus, and so of all the higher genera, under the *essentia* of a thing; in the 2d, the *differentia* of the species, which gives its

limitations and distinctive characteristics; in the 3d, whatever may be accidental to it, and so different at different times without changing its identity, and which, therefore, cannot enter into science properly so called; in the 4th, the quantity, whether discrete, as the number, as 1, 2, &c., or continuous quantity, as finite, large, small, infinite, &c.; and finally, the relations of an object in time, as fixed by its antecedents and consequents, causes and effects. Of course there are some of these categories into which some objects will never fall, as, for example, a mathematical figure cannot fall into the 3d or 5th, as no matter that is truly accidental to it enters into the discussion of such a figure; nor do we speak of it in relation to its cause or its effects, since it is not considered as an objective reality at all.—Still another classification of categories of great practical value may be given, based upon the quality of the term by which the subject is denoted. Thus, if the subject be a negative term, we can affirm of it only negative predicates; if a privative, we can affirm only the *essentia* of the proximate genus, with a denial of some of the properties of its species. Among positive terms we have 1st the abstract and the concrete. The abstract are either (1) general, denoting a genus, or (2) individual, denoting the abstract conception of a single property, as whiteness. Of neither of these can we predicate any terms implying their concrete existence, their quantity or extent, their divisibility, cause or effect, &c., since all these things can belong only to concrete and therefore substantial realities. Concrete terms may be either (1) individual or (2) collective. Thus, congress, which is a collective term, is as really a concrete reality as any one of the men who are members of that whole. And yet it holds of all collective wholes that some things may be predicated of them which cannot be predicated of any individual member or part taken individually, nor yet of them all taken generally or as a genus; and so, conversely, predicates may be affirmable of each member taken separately which cannot be affirmed of them taken collectively: e. g., each member of congress is a man, and may be a Christian; congress is neither a man nor a Christian. Then, finally, the subject may denote (1) merely a subjective reality, or a conception which exists only in the mind, as when we speak of a triangle, a circle, &c.; or (2) it may denote an objective reality which exists out of the mind, and as such is cognized by the mind itself. In this case our classification would be based, like that of Kant's, not upon an *à posteriori* classification of the predicates as actually observed in use (for no such classification is or even can be complete and satisfactory), but upon the *à priori* conditions of cognition as indicated by the processes of cognition and the formation of conceptions and the terms to represent them. And it is obvious that if this classification should be followed out it would determine for us *à priori* what may be affirmed of any given subject, and

so give assurance of completeness in the results of our investigations, and of certainty in our reasonings and discussions.

CATEL, CHARLES SIMON, a French musician, born June, 1773, died in Paris, Nov. 29, 1830. He was one of the first professors appointed to the conservatory of music in Paris, and is the author of a number of musical works, of which his *Traité d'harmonie* is the best.

CATEL, FRANZ, a German artist, born in Berlin, Feb. 22, 1778, died in Rome, Dec. 19, 1856. His earliest efforts were designs for illustrated almanacs. He then painted in oil and water colors, and took up his abode in Rome in 1812. Overbeck, Schadow, and Cornelius gave him much encouragement, and he painted historical and *genre* pieces, and landscapes. During a residence in Sicily, about the year 1818, he painted a large number of views of Mount Etna, and other prominent places on the island. He died rich, directing his fortune to be invested for the benefit of poor artists.

CATENARY, the curve formed by a chain hanging from two points, not in the same vertical line.

CATERPILLAR, the common name of the larvæ of lepidopterous insects, including butterflies and moths. Caterpillars vary greatly in form and appearance, as may be judged from the fact that about 600 species are known in New England alone, and probably many are yet unknown. The body is composed of 13 segments; the 1st constitutes the head, containing the jaws and oral appendages; the 2d, 3d, and 4th form the thorax of the future insect, and the remaining ones make up the abdomen. The head is rounded, and of a harder consistence than the body; on each side are 6 very small *ocelli*, or simple eyes, with a very convex cornea and a spherical crystalline lens, 2 short antennæ, and a mouth, with strong jaws moving transversely; the mandibles are hard, for breaking up the food, while the maxillæ are soft and adapted rather for holding it; in the middle of the lower lip is a conical tube, through which issue the silken threads from which their nests and cocoons are made, and their suspensory fibres; a viscid fluid, enclosed in 2 long and slender bags, is poured out through the "spinneret" in a fine stream, and hardens into silk on contact with the air. The segments of the body are very nearly equally developed; the 2d, 3d, and 4th have each a pair of tapering, jointed legs, covered with a shelly skin and ending with a little claw; these are the rudiments or cases of the future limbs, and are the true organs of locomotion; some of the other segments are furnished with soft, jointless, fleshy, and contractile legs, called prop legs, which disappear with the larval condition, being only prolongations of the external covering and shed with it, like the nails and claws of the higher animals; the abdominal legs vary in number from 4 to 10, and are provided, around the margin of the sole, with rows of minute hooks capable of such direction as is necessary

for a secure hold. Some are smooth, at others hairy, and their external appendages, which serve for defence, are shed with the larval state. Where the middle of the body is unprovided with feet, the legs are carried in an arched or looped manner, which is very early known in the common species. These species are hence called *erect*, *surveyors*, and *geometers*: they are in a state of repose, fix the body on the hind legs only, and project the head in position from branches, which they resemble in direction, for the purpose of power of remaining thus in a position at a time must be due to the species which we have no idea in the species which have 8 to 10 pairs of legs, walk by short steps, in a continuous manner. Some smooth caterpillars, of the sphinx moth (commonly called the *worm*), have a spine or thorn upon the last segment of the body, directed backwards and curved; though this looks like a defence, it has been considered an offensive organ, its softness is such that it can wound. The larvæ of some of the terous insects, as of the saw flies (*Sawflies*), resemble caterpillars both in habits; but these false caterpillars are distinguished by their greater number of segments (18 to 22), and by the absence of hooks in their prop legs; the segments, having the same number of feet, are scaly and not soft and moist. On the side of the body are 9 openings, called *stigmata*, situated in the 2d, 3d, 4th, 5th, 6th, 7th, 8th, 9th, and 10th segments to the 12th, provided with these communicate directly with the respiratory organs, which are in the form of branching tubes; in the caterpillars the tracheæ are dilated into vesicles permeating every segment. The intestine is short and the digestive system is a series of gizzards, one for each segment, the greater part of it being in the head and thorax. Caterpillars vary greatly in size, the mean may be taken at an inch, exceeding this being large, while below it may be considered small. Some have only 8 feet in all are the moths' caterpillars, generally the moths' caterpillars are a caterpillar compared to that of a butterfly, great, and the rapidity of their growth is astonishing; there is no insect more voracious than the caterpillar, it can eat in 24 hours more than double its weight; though less voracious than the caterpillar, they are quite as destructive. Their fecundity and their voracity in the vegetable world. According to the common silkworm, which it attains its size from 1 to 40 lines and 95 grains; during

med 9,500 times in weight, and has eaten  
 ses its weight of food. The caterpillar  
 privet hawk moth on leaving the egg  
 about  $\frac{1}{8}$  of a grain, and at the end of  
 4, when it has acquired its maximum size  
 been known to weigh 142 grains, and to  
 over 4 inches in length, thus increasing  
 than 11,800 times its original weight.  
 ing to Lyonnet the larva of one of the  
 cater moths (*cosmus ligniperda*, Fabr., or  
*lyleutes* of Newman), during the 8 years  
 it is supposed to remain in the cater-  
 te, increases 72,000 times its first  
 by a great accumulation of fat for its  
 ment in the pupa and perfect states. Most  
 llars feed on vegetable substances, the  
 flowers, roots, buds, seeds, and even the  
 of plants; many domestic pests gnaw  
 and furs, leather, and fatty substances;  
 some are quite exclusive in their diet,  
 others are more indiscriminate feeders. When  
 they are very numerous, scarcely any plant  
 escapes their attacks, and at such times their  
 ravages are deplorable, reducing trees in mid-  
 summer to their winter leafless livery. Plants  
 with acrid juices are the favorite food of some  
 species, and the nettle and other spiny shrubs  
 are the natural habitats of many smooth and  
 tender-skinned varieties. Most feed on the  
 exterior of plants, but some of the most destruc-  
 tive and most delicate live in the interior of  
 branches and stems. The sweetest fruits, as  
 pears, plums, and apples, ripen and fall prema-  
 turely, the abodes of caterpillars; plums are  
 especially liable to be thus inhabited, while the  
 peach and apricot are free from all larvæ; it has  
 been observed that a single fruit rarely contains  
 more than a single caterpillar, the second inhabit-  
 ant, if there be one, being the larva of some  
 other order of insects. Wheat, rye, barley, and  
 other grains are infested by small caterpillars,  
 which gnaw away the whole interior without  
 any external perceptible trace, so that an appa-  
 rently sound heap may be only a collection of  
 useless skins; a single grain contains just the  
 quantity of provision necessary for the trans-  
 formation of the insect. Another example of the  
 instinct of the lepidoptera is seen in the fact of  
 their depositing their eggs on the parts of the  
 plant which will furnish an easily accessible sup-  
 ply of food to the caterpillar when it is hatched;  
 their eggs are found glued to fruits, and to flow-  
 ers that are to produce fruits, between the very  
 petals, so that the young find themselves sur-  
 rounded by an immediate supply. Caterpillars  
 are remarkable for the eagerness with which  
 some species will feed upon their fellows, in  
 preference to vegetable substances in profusion  
 around them. Different species select different  
 times of day for feeding; some eat at all hours,  
 some in the morning and evening, and others  
 only at night; a knowledge of these habits is  
 of great advantage for the easy destruction of  
 many pests of the vegetable garden. Though  
 generally disgusting objects, the contrast and  
 brilliancy of the colors in some of them are em-

inently beautiful. Some species herd together  
 in great numbers, constructing their silken  
 habitations in common; others live solitary,  
 exposed to light and air, or protected in rolled  
 leaves or silken sheaths; others burrow in the  
 ground, or conceal themselves in the stems of  
 plants and the pulpy substance of leaves. The  
 caterpillars which live in one nest all come from  
 the eggs of a single insect, and are generally  
 hatched on the same day; from 200 to 700 may  
 thus be found together, and may remain so  
 through the chrysalis condition, or may separate  
 at different periods of life; some, though liv-  
 ing in great numbers on the same tree, are soli-  
 tary with respect to each other, performing no  
 work in common; the most solitary are the  
 leaf-rollers, which are also the most remarkable  
 for their vivacity. For the mechanism of the  
 various abodes of caterpillars the reader is refer-  
 red to the works of Réaumur, Latreille, Kirby  
 and Spence, and other practical entomologists.  
 The attitudes assumed by caterpillars when at-  
 tempts are made to catch them are characteristic  
 of species in many cases; some roll themselves  
 into a ring and remain as if dead, the hairy ones  
 resembling little hedgehogs; others fall instantly  
 to the ground and try to escape by rapid flight;  
 some attempt to defend themselves by various  
 motions of their bodies. The mode of marching  
 adopted by the "processionary caterpillars" is  
 very remarkable; these live in society, and when  
 they quit their nest they go in a regular pro-  
 cession, a single caterpillar first and the others  
 in single file, or 2, 3, and 4 abreast; the line is  
 so perfect in the columns, that the head of one  
 is never beyond that of another in the row;  
 following their leader, stopping when he stops,  
 they make journeys from tree to tree in search  
 of food, returning to their nest in the same  
 order; they form their ranks, march, and halt,  
 with the precision of soldiers; when several  
 nests are in the same wood, the spectacle of  
 these creeping battalions, issuing forth and  
 returning at the same hour, is exceedingly inter-  
 esting; the processions generally take place  
 toward night. Another species, common in  
 pine forests and living together, walks in pro-  
 cession in single file, often very long, the head  
 of each in contact with the tail of the one in ad-  
 vance; they defile in a straight line, or in a  
 variety of graceful curves; they sometimes go  
 to great distances from the nest, always with  
 the same slow and grave step, following exactly  
 their leader; they return to the nest by the same  
 path, which they find not by the sense of sight  
 but of touch; the path of exit is covered as they  
 go by a silken tapestry, and they return upon the  
 same delicate carpet, however tortuous may  
 have been their way. In the article *BUTTERFLIES*,  
 it was mentioned that caterpillars change their  
 skins several times before attaining their perfect  
 state, spinning for themselves a sort of cocoon  
 of silk, interwoven with hairs of their own, with  
 bits of leaves, and even with particles of earth,  
 suspending themselves by silken threads, or  
 burying themselves in the ground; the reader

is referred to that article, p. 157. Those lepidoptera which pass the winter in the egg, live in the caterpillar form during a part of the summer; the eggs are protected against cold by the shell and by the sheltered or subterranean situations in which they are placed; others pass the winter as caterpillars, concealing themselves under stones and the bark of trees, or descending deep into the ground where the cold cannot reach them; the social varieties retire to their warm and water-proof nests; these come forth in the spring quite well grown, but most pass the winter in the form of chrysalis, in protected or in open situations; a few pass this season as perfect insects. The natural enemies of caterpillars are numerous; almost all insectivorous birds and poultry devour them eagerly; other insects not unfrequently feed upon them; and little maggots developed in their bodies from the eggs of the *ichneumonidae* cause thousands to perish prematurely. In the northern states there are about 1,000 different kinds of butterflies and moths; as each female lays from 200 to 500 eggs, these species, from a single female each, would on an average produce in a year 800,000 caterpillars; if one-half of these were females, the second generation would be 45 millions, and the third 6,750 millions; with such fecundity it may well be imagined that the destructive powers of caterpillars must be very great. The work of Dr. Harris on "The Insects Injurious to Vegetation," under the head of "Lepidoptera," gives an extended and valuable account of the ravages of caterpillars in America, particularly in New England; to this are referred those specially interested in the subject. Alluding to laws in France and Belgium which require the people to "uncaterpillar" their gardens and orchards, under the penalty of a fine, he thinks similar regulations might be enacted here with advantage, or at least that the states might offer a respectable bounty for caterpillars by the quart, thus affording remunerative and highly useful employment to children and otherwise idle persons. Many destructive caterpillars will be alluded to under the articles HAWK MOTTH and MOTH, and under the popular names of the most noted species.

CATESBY, MARK, an English artist and naturalist, born in 1679, died in London toward 1750. Having first studied the natural sciences at London, he afterward repaired to Virginia, and remained in America 7 years, returning to England in 1719 with a rich collection of plants. Encouraged to revisit America, he arrived in South Carolina in 1722, explored the lower parts of that state, and afterward lived for some time among the Indians about Fort Moore, 300 miles up Savannah river; after which he continued his researches through Georgia and Florida. After spending 3 years upon the continent, he visited the Bahama Islands, constantly occupied in delineating and collecting botanical and zoological objects. He returned to England in 1726, and issued in 1730 the 1st volume of his great work on the "Natural History of Caro-

lina, Florida, and the Bahama Islands; figures were etched by himself from his paintings, and the colored copies were under his own inspection. In this work has been twice republished, were found descriptions of several plants which are cultivated in all European gardens. He was a member of the royal society, author of a paper on the "Birds of Carolina" in the "Philosophical Transactions." His name has been perpetuated by Gronovius, a plant called *Catesbaea*.

CATFISH, one of the *malacopterygii* rayed fishes, of the family *siluridae*, and genus *pimelodus* of Cuvier; character: a smooth palate, the palatic bones cutting teeth, but with no band of teeth in those of the upper jaw; the head or snout with 8 fleshy barbules; skin naked. He describes 16 species as occurring in the water streams and lakes of North America; there are about 50 in various parts of the world.—The common catfish, or horned (P. *catus*, Linn.) is one of the most common fishes of our rivers, and is by inference as an article of food to all aquatic species except the pickerel; they are occasionally met with weighing 100 pounds. Length 7 to 9 inches; color dark, most black on the head and back, light on the sides, and white beneath, in front of the ventral fins, which are behind the pectorals. Upper jaw longer; tail nearly even and rounded; head smooth and flattened; snout and covered with a mucous secretion. 2 fleshy barbules on the top of the head between the snout and eye; at the base of the upper jaw are 2 thick fleshy teeth reaching to the middle of the pectorals, and there are 4 others under the lower jaw. The mouth is capacious. There are 3 spines midway between the eye and the base of the gills; the 1st ray of the 1st dorsal fin is strongly spinous; the 2d dorsal fin is also spinous; the pectoral fins have also a serrated edge; these spines become fixed and immovable at the will of the animal, and serve as formidable defensive weapons. Varieties sometimes found in this genus without ventral fins, and have been described as a new genus *terus*. This species is the most common in the New England and middle states, and is found in the great lakes and along the coast from Maine to Florida. It prefers muddy bottoms, as do all the species of the family. The great lake catfish (*pimelodus* *macrochirus* Lesueur) is from 2 to 4 feet long, and weighs from 6 to 80 pounds; it is found in Lake Huron and Ontario. This is of a deep olive color, and has the tail forked. Others are the Huron catfish (*P. carolinensis*, 10 inches long, found in Lake Huron), the northern catfish (*P. borealis*, Rich.), 30 inches long, found in the northern regions; the white catfish (*P. albidus*, Lesueur), of a pale ash color, 12 to 15 inches long.

; the mudfish (*P. punctulatus*, Cuv.), 8 feet long, of a brown color spotted with ; from Louisiana. Among the large es found in the Ohio river and its tributaries are the *P. æneus* (Les.), 2 to 3 feet long; *P. albus* (Les.), 1 to 4 feet long; *P. cupreus* (L.), 1 to 4 feet long; *P. limosus*, *P. caruleus*, and *P. xanthocephalus*.—The catfish are h in their movements, securing their rather by stratagem than by swiftness. ale moves about with her young, like men with her brood. Though their flesh esmally esteemed in the country and on western rivers, it is very insipid to sons accustomed to salt-water fishes. Catname applied to other species of different genera, and among others to the ferocious *Phycis lupus* (Linn.), more properly called wolf-fish.

CATGUT, the intestines of sheep and other s, dried and twisted, used for strings of cal and other instruments. How this name to be applied to the strings it designates can explain. Shakespeare in an old or "Cymbeline" alluded to "horse hairs calves' guts," which in later editions is ed to cats' guts. In Bacon's "Natural history" mention is made of "strings of guts" a viol; but no early allusion to the in- of the cat being used for this pur- is anywhere met with. The dulcet strains are emitted by the organs of this animal cease with its life, and the viscera of the t sheep are almost exclusively selected to w forth from the harp, guitar, and viol those evenly sounds which harmonize so little with nature of the material which produces them. e process of preparing these cords is an art ich has received the attention of many ntific men, and is described in detail in y works upon arts and manufactures, as by Ure and Mr. Tomlinson in their dictionaries, with great minuteness in Laboulaye's *Dictionnaire des arts et manufactures*, in which, r the head *Boyauderie*, is given a volumi- memoir upon the subject by M. Labar- . This essay obtained for him the prize e *Société d'encouragement*, and demon- ed that by the use of his disinfecting liquid, chlorite of soda, the nauseating putrefac- of the materials and the results of this : be avoided. In the establishments where ade of manufacturing these cords is con- d, men and women are alike engaged in rious processes, which, from the descrip- ven, appear to be the most disgusting in : human beings are employed. M. Labar- states that no one can express the disgust ienced on first entering one of these work- ; and yet, he says, to show the influence bit upon man, there is no lack of work- nor are they more frequently sick than engaged in other employments. The eating odor in which they live never leaves t, even after their Sunday cleaning; one ntly recognizes it after one visit to the

place of their labor. The membranes are subjected to numerous different processes, lasting several days, to thoroughly clean them. They are exposed to fumes of burning sulphur to purify them, and are slit and twisted into different sized cords according as they are designed for musical strings, whip cords, batters' cords, or clockmakers' cords. They are then dyed, and afterward, as they are stretched upon frames, dried and hardened by exposure to a temperature of 180° to 200°. Lastly, they are cut off and coiled up for sale. The English fail to make good musical strings. Theirs have not the strength of the Italian strings, and the smaller ones are frequently fractured before they can be brought to the proper pitch. The cause of this is supposed to be the fatness of the English sheep, the intestines of lean animals being much stronger; in this respect the Italian sheep have a decided advantage. Otto, in his "Treatise on the Violin," says that the best strings are those from Milan, sold by the name of Roman strings, and as these are imitated by inferior cords made in Bohemia and the Tyrol, he gives the following as the marks of the best article: "The Milanese strings are as clear and transparent as glass. The third string should be equally clean as the first. They must by no means feel smooth to the touch, for they are not ground or polished off by any process, as all other manufactured strings are. If a good string be held by one end in the finger and opened out, it will recoil to its former position like a watch spring. Every string when stretched on the instrument should look like a thin strip of glass on the finger-board; those which are of a dull and opaque appearance are useless. Their elasticity is after all the best criterion, as no other strings which I have tried have that strength and elasticity for which the Milanese are so much esteemed."

CATHARINE I., empress of Russia, born at Germunared in Sweden in 1682, died in St. Petersburg, May 17, 1727. Her father was a Swedish quartermaster, John Rabe; her mother, Elizabeth Moritz; her own original name, Martha. After the death of her husband, Elizabeth Rabe returned to Livonia, where she had married him, and where she soon died, leaving several children of her first husband (afterward made counts by Peter the Great), and Martha, then a child of 8 years. A sexton of the place took care of the destitute orphan, from whose house she was then taken to that of the provost Glück, at Marienburg, who educated her with his children. In 1701 she married a Swedish dragoon of the garrison of Marienburg, but the campaign of 1702, in which he had to serve, and the capture of Marienburg (Aug. 28) by the Russians, under Sheremetieff, separated them forever. Martha, together with the family of her protector, Glück, was made captive by the Russian general, who treated the old clergyman kindly, but retained the females. At the distribution of the spoils, she was allotted to Gen. Bauer, whose mistress

she was until she was ceded by him to the princess Mentchikoff, who employed her in household services. It was there that Peter the Great saw her, was captivated by her beauty, and made her his mistress (1703). She adopted the Greek creed, and with it the name of Catharine Alexievna. In 1706 she bore Catharine; in 1708 Anna, afterward duchess of Holstein-Gottorp, and mother of Peter III.; in 1709 Elizabeth, afterward the empress of Russia. She maintained her influence over Peter by the vivacity of her spirit, her unwearied activity, and her good temper. She shared the troubles and fatigues of his campaigns, and frequently calmed the wild outbreaks of his savage temper. When in 1711 his great rival, Charles XII., who, after the defeat of Pultowa (1709), had found refuge and protection in Turkey, had succeeded in arming that state against the Russians, and Peter, after an imprudent march, found himself reduced to the extremity of starving on the banks of the Pruth, or surrendering his army, Catharine, with the assistance of Ostermann and Shaffiroff, saved the desponding emperor and his new created state by bribing, at the sacrifice of her jewels, the Turkish grand vizier. Peter proved his gratitude by marrying her secretly, by acknowledging her as his wife in 1712, and declaring her empress in 1718. As such she was crowned in Moscow in 1724. Of 5 children she bore after her marriage with Peter, most died in their early infancy. The determination of Peter to make her his successor was shaken by his suspicions about her conjugal virtue, and still more in 1724 by his conviction of her infidelity, in consequence of which the chamberlain Moens was beheaded (ostensibly for mismanagement in office), his sister ignominiously flogged, and his 2 sons sent to the army in Persia. It has been asserted that Catharine, having been shown by Peter the head of Moens, still hanging on the scaffold, said calmly: "What a pity that the people of the court are so corrupt." She succeeded, however, in strengthening her position by reinstating Mentchikoff in the favor of Peter, which he had previously lost by his devotion to her. But still so doubtful was her situation, that at the death of Peter (Jan. 28, 1725), which was kept secret until her succession was secured, she could not avoid the suspicion of having poisoned her husband. The archbishop of Pleskov, Theophanes, declared under oath to the people and the army that Peter on his deathbed designated her as the worthiest of succession, and the guards, the synod, and the high nobility, gave their consent, and the people their oath of fidelity to the first "empress" and autocrat of all the Russias. The policy of Peter was continued under the leading influence of Mentchikoff; but soon the caprices of the empress, who was beside guided by favorites, and subject to intemperance in drinking, were felt in the management of affairs, and blunders committed, while her ruined health prepared a sudden end. Her successor was Peter II. II. CATHARINE II., empress of Russia,

born at Stettin, May 2, 1729, died at St. Petersburg, Nov. 17, 1796, was the daughter of Christian August, then governor and afterward reigning prince of Brunswick, and princess of Holstein-Gottorp. She received her the names Sophia and Augusta, and her education. At an early age she was betrothed to the empress Elizabeth, according to the intention of Frederic the Great, to be the nephew and successor, Peter III., who brought her to the court of St. Petersburg, where she adopted the Greek creed, received the name of Catharine Alexievna, and was crowned empress in 1745. But all the refinement and refinement of a life of luxury and pleasure, which she had formed of a life of luxury and pleasure, soon vanished under the influence and repulsive treatment of her husband, who, though not incapable of good, was rude, dissolute, and passionate. Her lively temper could not be consoled by the consolation of continued studies, and retirement in which she lived during the reign of Elizabeth, but sought to form connections which were of no use to her. Among the persons who surrounded her, Count Soltikoff won her liveliest affection by his spirit and good looks, and his popularity with the favor and envy had sent him as ambassador to foreign courts. At that time (1759) the mother of Paul, afterward her son, was in the empire. Poniatowski, a handsome and accomplished Pole, won the place on his first appearance at the court, and was favored in her favors by the empress Elizabeth. He caused Augustus III., king of Poland, to name him as his ambassador, but was soon recalled by intrigues of representatives of Austria, who saw in his sympathies for France a danger to their influence over Catharine and Russia. For the French-Russian-Austrian alliance was recalled, and Gregory Orloff, an object of her favors. When in 1762 Elizabeth died, the ill feeling between Elizabeth and Catharine broke out, and the life of both, by the public amours of Peter III., was filled with hatred. Catharine supported her husband's abdication in favor of Elizabeth's son, Paul, and Orloffs and their friends were persecuted and sought revenge her. The favorite, Panin, and Princess Lubov, a fascinating woman, became the chief agents in the conspiracy against Peter, which was promoted by the general discontent of the nation and army by the discipline, as well as by the influence of the unfortunate monarch, who was joined by malcontents, and ambitious courtiers. They were detected and one of the conspirators was executed, when they hastened to St. Petersburg on the night of July 8-9, 1762. Catharine fled from Peterhof to St. Petersburg, and was crowned on a peasant's way on a peasant's way.

the guards, who hailed her as empress, though, according to the original plan, her son Paul was to be declared emperor and herself regent; but this had been changed by the Orloffs, and the future senator Teploff read, instead of the prepared manifesto, a new one in the Kasan church. Peter was soon seized, and after a few days strangled in prison. To gain pardon the sooner for her part in the crime, Catharine made the most splendid promises to the nation, flattered its prejudices, exhibited great devotion to the national religion and its priests, was crowned with great pomp at Moscow, and made a show of extraordinary zeal for improvements in industry, commerce, and the navy, and for reforms in the administration of justice, as well as in the management of the external affairs of her vast empire. Courland was compelled to depose its duke, Charles of Saxe, and to submit again to the rule of Biron, who had made himself hateful by his cruelty. Her influence prevailed in Poland after the death of Augustus III. (1763), in

election of her favorite Poniatowski as king the name of Stanislas Augustus, from affection and weakness she justly expected the extension of her influence over the laboring state, distracted as it was by religious and civil dissensions. But this happy commencement could not allay the hatred of personal malcontents; attempts against the empress were plotted at Moscow and Petersburg, and the aim of setting upon the throne of the empire, Ivan, son of Anna Carlovna, who had already atoned by 24 years of imprisonment under Elizabeth and Catharine, for having worn as a child, for a few months, the imperial title before the accession of the former. The violent death of Ivan, in his prison at Schlüsselburg (1764), put an end to these schemes, and Catharine could now enjoy more easily the pleasures and festivities of her court, troubled but little by its intrigues about favors and favorites. The convocation of representatives from all the provinces of the empire for discussing the reorganization of justice, at Moscow, was a new manifestation of her political activity, as were the rules elaborated by her, and read in the first session, of her political wisdom.

But the rude Samoieds spoke of oppression by their governors, and a proposition for enfranchisement of the serfs was soon made. Catharine was afraid of the consequences, and hastily dissolved the assembly, who declared her mother of the country. Greater were the results of her external diplomacy. Poland, undermined by her intrigues and her protection bestowed on the dissidents, soon became a prey to its neighbors. The confederation of Bar (1768), under Pulaski, Potocki, and other patriots, the weak opposition of France to Russia, and a declaration of war by the Turks, could not save the unhappy republic, and its first division by Russia, Austria, and Prussia, ensued in 1772, and Catharine received a proportionate share. The Turks were

humbled by her armies under Romanzoff, on the Pruth and on the Kagool (1770), by the conquests of Ohocim and Bender, as well as by her fleet under Alexis Orloff, which won the great naval victory of Scio, and burned the Turkish fleet in the bay of Tchesme; and the last disasters of the great vizier compelled the Porte to the peace of Kootchook-Kainarji (1774), and its cession of Kinbourn, Azof, Yenikale, Kertch, and both Kabardahs to Russia. Crimea was made independent, soon to become a prey to Russia. Having happily subdued and severely punished the revolt of the Cossack Poogatcheff, a pseudo-Peter, in the eastern provinces (1771-74), she now formed the plan of expelling the Turks from Europe, and founding a new Byzantine empire under a prince of her house. This scheme, favorably regarded by some philosophers of France, was eagerly promoted by her new favorite, the ambitious Potemkin, who ruled her no less arrogantly than he did the empire. One of the gates of Moscow received this inscription, "Way to Constantinople;" one of her grandsons the name of Constantine; and plans were made on the banks of the Neva for the restoration of Sparta and Athens. After a journey through the eastern provinces which had been the scene of the revolt, she undertook a new one, in 1767, through the southern parts of her empire, to the lately conquered Taurida (in part the ancient Tauris). Potemkin made this a most magnificent triumph. The eyes of the empress were dazzled by enchantments; palaces rose on desert prairies, to shine for a day; villages and cities, of which only the walls were real, were seen from afar, covering the barren plains of the Tartar nomads; masts and flags rising above the sands showed fictitious canals; festivities and bonfires followed each other; and dances and song proved the happiness of a population of a hundred nationalities, which ran in the night to appear next day in new scenes of illusion. Catharine, who never forgot to listen to the applause of the French philosophers, amused herself and her court at the same time, with the translating of Marmontel's *Bélisaire*, but still pursued her diplomatic schemes. Poniatowski, who came to see her after 23 years, near the frontiers of his dismembered state, was repaid with kind promises for ancient personal affection and new political fidelity. Joseph II. of Austria, who came to Kherson, was won for a common war against Turkey, which ended for Austria with his death (1790), and without gain, and for Russia, after the conquest of Otechakov by Potemkin, after the great victories of Suwaroff, and his bloody conquests of Ismail and Bender, with the peace of Jassy (1792), and the acquisition of Otechakov and the country between the Bog and Dniester. This result, so slight in comparison with the expected overthrow of the Turkish empire, was owing in part to a war with Gustavus III., the gallant king of Sweden, who marched against St. Petersburg, but was happily checked in Finland by his officers refusing to advance, and was thus

compelled to make peace (1790); in part to the opposition of England and Prussia; but principally to the bravery and fanaticism of the Turks in defence of their country. The progress and victories of the French revolution, though giving her a kind of satisfaction by the humiliation of several states once mighty, filled Catharine with horror, and made her soon forget all her predilections for France, and her own vaunted liberalism; she assisted the *émigrés*, broke off every communication with the French government, and even made an alliance with England. Poland was in the mean time the chief object of her attention. Its Long diet had completed the new constitution of May 8, 1791, which promised to give union and vigor to the nation. Catharine, while at war with Turkey, had approved of it, like Frederic William of Prussia, who had his war with France. But scarcely were these wars finished, when Poland was treacherously attacked from both sides. A Russian army of 100,000 men was sent to support the aristocratic faction that had formed the confederation of Targovitza against the constitution. The nephew of the king, the future French marshal, Joseph Poniatowski, in vain led the Polish army against them; Kosciuszko proved in vain to be a worthy disciple of Washington. The king, persuaded by Catharine, deserted them, and went over to the confederation, and the second partition of Poland followed, executed by Russia and Prussia alone. The Russian cannons compelled the diet of Grodno to sanction it (1793). The great rising of the betrayed nation in the following year commenced with the massacre of the Russians, and with glorious victories, under Kosciuszko as dictator, but ended with his defeat at Maciejowice (Oct. 10), and with the taking of Praga (Nov. 4) by Suwaroff, who repeated there the slaughter of Ismail and Bender. "Bravo, field-marshal!" was Catharine's answer to his report: "Hurrah, Praga, Suwaroff." The three great neighbors of Poland now took the whole of it, and destroyed even its name (1795). A year before, Catharine had annexed Courland to Russia. She now undertook a war against Persia, when she died of apoplexy, after an agony of 30 hours, leaving her empire, so greatly enlarged, to her son Paul.—Catharine was possessed of great talents, susceptible of great ideas, and showed often a manly spirit and energy; her ambition appeared grand, but at the same time she was a woman in caprice, a slave of her sensuality and vanity, extremely selfish, and sometimes cruel. Her numerous favorites, some of them her tools, and some her masters, were elevated by their official situation in the palace, by privileges, promotions, and presents, to dignity in the state; while she was, on the other hand, prompted by the love of glory to flatter the representatives of public opinion, particularly in France, to invite Voltaire to her court, to call D'Alembert to complete the French *Encyclopédie* in St. Petersburg to suffer the familiarities of Diderot, to have a

regular literary  
write herself se-  
mote literature and  
ture, in her empire;

CATHARINE, SAINT, a saint of  
of Rome, whose anniversary is cele-  
Nov. 25. She was a virgin of A  
is said to have suffered martyrdom  
min. The military order of the An-  
Catharine, on Mount Sinai, was established  
the protection of the pilgrims who  
worship at the tomb of the saint, w  
this mountain, where her corpse was  
to have been found. St. Catharine was  
to have been of high descent, and to  
possessed remarkable mental attainments.  
she has been often chosen as a patron of  
of philosophy. Several of the gr  
masters have furnished pictures of St.  
the most beautiful is that by Corra-

CATHARINE OF ARAGON, a  
prince of Wales, and of King Henry  
England. She was the daughter of  
of Aragon and Isabella of Castile.  
born in 1483, in the city of Alcalá  
while her mother was engaged in  
tion against the Moors, died in 1500.  
Granada was not finally surrendered  
9th year of her age; and much of  
hood was actually passed in the ro  
At an early age, in accordance with  
tom of the time and the policy of her  
try, she was betrothed to the v  
Arthur of England, son of Henry  
never was marriage contracted  
auspices. Catharine had au-  
ents, dignity, virtue, piety, and prudence.  
out her coldness, austerity, fanatic  
zeal. She had all the dark-glov  
stately beauty of her native land: a  
per, a kind heart, a gracious  
the young prince to whom she was  
was handsome of person, eminent  
and excellent of disposition.  
the princess and her train  
but a fierce storm drove her  
of Castile; and it was not  
bleak and gloomy weather, that she  
Plymouth, and was received  
pomp and splendor of a  
by the joyful greetings of  
western counties. On  
of St. Catharine, her p

or, she made her solemn entrance to  
 over London bridge, whence she  
 conducted to the cathedral of St. Paul,  
 thence to the bishop's palace at Lambeth,  
 she was entertained on that night, and  
 one intervening, as well as on that follow-  
 the wedding ceremonial, which was per-  
 l on the feast of St. Erkenwald, Nov. 14,  
 It is well here to state, that it was  
 and on oath, many years afterward, when  
 necessary for reasons which then  
 to establish the facts of the conjugal re-  
 that they lived as man and wife happily  
 at Ludlow Castle; but it was for a  
 time only, as Arthur died of the plague  
 in 6 months after the consummation of the  
 2. On the death of Arthur, Henry  
 of York, who had been educated for the  
 and was intended to hold the archbish-  
 of York or Canterbury, became prince of  
 and heir to the crown; and it was at  
 proposed by Henry VII., and acceded to  
 Ferdinand, contrary to the wishes of the  
 widow, who was now in her 19th year,  
 who wrote to her father earnestly depre-  
 the alliance, though professing entire  
 ce to his wishes, that she should be  
 married as soon as Henry, who was only in  
 12th year, should arrive at the age of pu-  
 rty. A dispensation was easily obtained  
 from the reigning pontiff, Julius II., and  
 the ceremony of betrothal took place at the  
 use of the bishop of Salisbury in Fleet street,  
 on the 25, 1503. For several years Catharine  
 resided at the court of England, but on Henry  
 reaching his 15th year, his father, who had  
 to his own fair and virtuous wife, and who  
 had it in his mind to contract a marriage him-  
 self with Joan, the elder sister of Catharine,  
 widow of Philip of Burgundy, until he  
 found the union impossible owing to the incur-  
 able insanity of the lady, compelled him to en-  
 voyn a protest against his marriage with his broth-  
 er's widow. This protest was kept strictly a  
 close secret, nor was its existence ever known  
 suspected until it was produced years after-  
 ward, in order to give a color to the proceed-  
 ings in the case of the annulment of the mar-  
 riage. At this very time, however, so far from  
 leaving the lady or wishing to avoid the  
 match, Henry was violently in love with Cath-  
 arine; and his father actually took measures  
 to restrict their intercourse, as fearing lest they  
 would contract a clandestine marriage. Not  
 long after this interlude, however, in the  
 year 1509, Henry VIII. succeeded to the crown  
 on the demise of his father, and almost his first  
 business was to hurry on his marriage with Catha-  
 rine. It was celebrated at Greenwich on the  
 feast of St. Barnabas, with great pomp and re-  
 ceiving, to the delight of her father, who cele-  
 brated the event with grand festivals and tilts,  
 after the Moorish fashion, with the jereed, in  
 Spain. For many years the marriage was hap-  
 py and prosperous; the queen lent herself to the  
 wishes of her husband for pomps, pageantries,

maskings, and diversions of all kinds; accom-  
 panied him in his royal progresses; moderated  
 his hasty temper; ever interposed on the side  
 of mercy and justice; in every way exercised a  
 beneficent influence over him; and used her  
 power only for his own good, and that of his  
 people. During his absence in the conduct of  
 the war with France in 1518, Henry left her  
 the sole regent of the kingdom; and on his re-  
 turn, in the following September, he rode post  
 from Dover to Richmond incognito, to surprise  
 the queen, and there, to borrow the words of  
 Hall, "was such a loving meeting, that  
 every one rejoiced who witnessed it." Yet at  
 this very time he was false to her, with Eliza-  
 beth Taillebois, who was his first, and continued  
 for many years his only mistress, until he be-  
 came enamored, first of Mary, and then of Anne  
 Boleyn. In the year 1516, having been already  
 twice a mother of princes, who did not long  
 survive their birth, Catharine bore a girl, who  
 was called Mary, after her aunt, the beautiful  
 queen of France, and who was afterward of un-  
 happy memory as the persecuting queen of Eng-  
 land. Eighteen months passed, and she became  
 again the mother of a boy, who again died as soon  
 as he saw the light; a disappointment which  
 troubled Henry so much, that he publicly  
 avowed his son by Elizabeth Taillebois, and  
 created him duke of Richmond. In 1520 oc-  
 curred the famous field of the cloth of gold,  
 memorable in the life of Catharine for the fact  
 that then Henry first became acquainted with  
 Anne Boleyn. In about 2 years afterward,  
 hearing that Anne was betrothed to Henry  
 Percy, son of the duke of Northumberland, he  
 took so much pains to break off the match by  
 the aid of Wolsey, as proves that he was al-  
 ready desperately enamored of her. The lady,  
 however, who did not care to be his concubine  
 and saw no chance as yet of becoming his wife,  
 was extremely indignant, and never forgave  
 Wolsey his share in the matter. In the year  
 1527 she was recalled to court, which she had  
 left in anger, and was reinstated in her old of-  
 fice of maid of honor, her father being created  
 Viscount Rochefort. From this time forth, Cath-  
 arine's life was as miserable as her conduct was  
 irreproachable. From this moment Henry  
 was determined to abolish his marriage with  
 Catharine, and to make the maid of honor, who  
 had perhaps thus far preserved her innocence,  
 his queen. The mock trial of Catharine, her  
 appeal to Rome, her beautiful address to her  
 husband, her leaving the court as one wherein  
 she could not have justice, are facts familiar to  
 all readers of Shakespeare. For 6 long years  
 the cruel agony continued; but when, in 1533,  
 contrary to all Henry's hopes, the marriage of  
 Catharine was declared by the council at Rome  
 to be valid, Anne, who had been now some time  
 almost openly his mistress, under the title of  
 marchioness of Pembroke, being pregnant, a  
 secret marriage was resorted to, the old one  
 being yet undissolved, in order to legitimate the  
 unborn child, whom Henry in his insane anxi-

ety for an heir had predetermined to be a son. At this time Catharine was expelled from Windsor, and informed that she was no longer queen, although she was in all respects as much and as legally so as ever, when she went her way meekly with her ladies, quitting the royal abode in which she had passed so many happy and unhappy days, with the beautiful and touching words: "Go where I may, I am his wife, and for him ever will I pray." She never again saw her husband or her child. Until after the public marriage of Anne, she was allowed the title of queen and the empty honor to be served on the knee, and to be treated with the external deference due to the rank which had been so rudely wrested from her. We know only of Catharine's life during her seclusion, between her abandonment and her divorce, that her time was passed among her faithful ladies in acts of charity, devotion, piety, varied only by the feminine arts and occupations of embroidery, to which she had always been addicted. Wherever she lived, the poor inhabitants of her neighborhood profited by her goodness, loved her, prayed for her, followed her with their sighs when she was removed from among them. In the mean time, finding that he could not have the marriage annulled at Rome, Henry determined that he would have it done in England, and to that end, that he would overthrow the church of Rome, build up an Anglican church, of which he would be pope himself, with a college of prelates and a clergy of his own, who should do his business in clerical matters, as his ministers did in civil affairs, at his sole bidding. All this Cranmer, who was raised to the archbishopric of Canterbury, vacant by the death of Warham, undertook to do for him, and speedily effected. His first step was to open his court at Dunstable, for the trial of the case of Queen Catharine's marriage; and as she steadily denied the validity of the court and its jurisdiction, and refused to appear, he pronounced her contumacious, and declared the marriage void and of no effect from the beginning, as incestuous and consummated in defiance of divine prohibition. The princess Mary was declared illegitimate, and Catharine was desired to abstain from the title of queen and content herself with the style of dowager princess of Wales. She, however, declined to renounce her title, and died, leaving a letter to her husband concluding with those touching words: "Lastly, do I vow that mine eyes desire you, above all things."

CATHARINE OF BRAGANZA, wife of Charles II., king of England, born 1638, died Dec. 31, 1705. She was the daughter of John IV., after 1640 king of Portugal, and brought her husband, in 1662, beside a rich dowry, Tangiers in Africa, and Bombay in India. She met at the court of the dissolute Charles bitter mortifications, which, however, she soon resigned herself to suffer with equanimity and mildness. Lord Clarendon says: "The queen had beauty and wit enough to make her-

self agreeable to the king; yet according to the de and di country, bred in seen only the w conversed with the and, without doubt, her in enough disposed to be one of And from this restraint she was called be a great queen, and to a free court in a court that was to be upon the formed, and reduced from the licentious age to the old rules and had been observed in better regular and decent position of men and women clined to submit, nor the some struggle she submitted the tious conduct, and from that time lived on terms with him till his death." Acc against her of plots in favor of religion were received favorably by of commons, but rejected by the the death of Charles (1 she was turned to Portugal in 1640. country by her brother, Dou she proved her ability in the war which she carried on with firmness success, though already 67 years old.

CATHARINE OF FRANCE, OF VAL of England, born in Paris, Oct. 27, 1 the abbey of Bermondsey, Eng., J She was the youngest child of Ch France, and his queen, Isabella or Her father having become mother being absorbed by itics, Catharine, as well as sisters, was utterly neglected fancy. She became, however, so much so, that Henry V. of asserted his claim to the crown plied for her hand, but demanded dowry, consisting mainly in of France declining these te vaded the country, and, Agincourt and the capture of his application, which was entertained. Meanwhile, taken place: the duke of Fearless, had been Philip breathed nothing the dauphin Charles; Is on destroying her own son; into negotiations with Henry whi the treaty of Troyes, May 20, 1 Henry V. was to receive the Catharine and succeed to the throne of the death of Charles VI., the kingdom being placed in time. "On Trinity Sun Monstrelet, "the king of lady Catharine at Troyes, in near which he lodged. Gr nificance were displayed by had been king of the whole dal music was the

was taken to England and crowned in 1421. Henry, being obliged to return to France, left his young wife in England, where she gave birth, Dec. 6, to a son, after- Henry VI. She was soon recalled to France where she found her husband dying. Shortly after his death (Aug. 31, 1422), his son was proclaimed king of France and Catharine now secretly married Francis I., a handsome Welsh knight, who, according to some chroniclers, was the son of a prince of Beaumaris, while according to others descended from a prince of Wales. Suspicions were awakened among the guardians of the young king, who behaved toward her with jealousy which is believed to have precipitated her death. Her eldest son by Owen Tudor, of Hadham, was the head of the Tudor family who ascended the throne of England half a century later.

CATHARINE DE' MEDICI, the queen of Francis II., and mother of Francis II., Charles IX., and Henry III., kings of France, and only daughter of Lorenzo de' Medici, born in Florence in 1519, died in 1589. In 1533, when she was but 14 years of age, the pope, Francis VII., her uncle, negotiated the marriage of Catharine with Henry, duke of Orleans, and son of Francis I., who, it is said, would have consented to the match, but that he was sure that Henry would never ascend the throne of France, and that he was in extreme want of money, with which the pope was prepared to supply him. Entering the court of France in a somewhat secondary position, she endeavored to conciliate all parties, win all affections, and be every thing to all persons, although in the mean time to care nothing for the affairs of state and to shun the turmoil of business. When she came to France, the duchess of Angoulême, and the celebrated Diana de Poitiers, afterward duchess of Valentinois, were ostensibly the mistresses of her father-in-law, the king, and of her husband; and to both she assiduously attended her court, though they notoriously hated each other. Nor when her husband became, by the death of his eldest brother the dauphin, and subsequently by the death of his father, the king of France, did she alter her policy or influence, whether in the affairs of state or in his private and domestic arrangements, with her husband, or with his mistress. The duchess of Valentinois was virtually queen of France, and at a grand tournament held at the castle of Tournelles, given in honor of the marriage of his eldest daughter, Elizabeth, with Philip II., king of Spain, in 1559, a splinter from a broken lance of De Lorges, count of Montmorency, entered the eye of Henry, and cut him off in the midst of a splendid and victorious career. By his death his son, Francis II., a weak stripling, weak both in health and intellect, lately espoused to the beautiful young queen of Scots, the hapless Mary, who was, on her mother's side, a Guise de Lorraine, succeeded to the throne, and the ambition of Catharine

flattered itself at once that she was now about to grasp position. But she was disappointed; for the weak and uxorious king was wholly under the influence of his beautiful bride, and she was as completely under the rule of her maternal uncles, the celebrated Le Balafre, Francis duke of Guise, and the cardinal Lorraine, who were in no sort favorable to the schemes of the queen mother. Francis about this time began to suffer from constitutional earaches. Catharine, who cared nothing for religion, connected herself with the Huguenot leaders, Condé, Coligni, and the king of Navarre, and a plan was laid for seizing and imprisoning the young sovereigns at Amboise, bringing the Guises to the scaffold, and governing the realm by a council of regency, composed of the Huguenot princes under the guidance of Catharine. The plot, however, took wind; the princes were compelled, in order to avoid the suspicion of complicity in the conspiracy, to witness the slaughter of their partisans; while Catharine, finding that their arrow was shot in vain, immediately deserted them, and joined the party of the Catholic league. The next plan was to assassinate the duke of Condé, in the presence of both Francis and Mary at Orleans, which city they were about to visit in state, on a royal progress; and on Francis positively refusing to give his assent to the murder, one of the Guises is said to have exclaimed: "Now, by the double cross of Lorraine, but we have a poor creature for our king!" It seems more than probable that the death of Francis II. was at once resolved, and there is little doubt that he died of poison, dropped into the porches of his ear while sleeping, not without the privity of Catharine, who, by the accession of Charles IX., a minor, succeeded as regent (1560) to the actual if not the nominal sovereignty of the realm. She now gave full swing to her atrocious genius. She first plunged all her children, in the flower of their youth, into such a vortex of licentious pleasure and voluptuous dissipation, that, as she intended, they were speedily divested of all moral sense and unfitted for every sort of mental activity or exertion. It was on the occasion of the marriage of her daughter Marguerite de Valois, with Henry of Navarre, that Catharine prevailed on Charles to give the orders for the fatal massacre of St. Bartholomew's, executed on Aug. 24, 1572, on the signal given by the tolling of the bell of St. Germain l'Auxerrois. From the moment of that terrible event, his consent to which had been wrung from him most reluctantly, and which it is believed he would have counteracted when it was too late, the unhappy Charles was a prey to the most horrible tortures of remorse, nor could he conceal the detestation he felt for the mother who had plunged him into such an abyss of blood and guilt. Catharine, it seems, had never loved him, nor Henry either, who was now absent in Poland, of which remote country he had been elected king, and whither he had gone reluct-

antly, at her urgent solicitation, amounting almost to compulsion. Francis, duke of Alençon, was her favorite, as of a spirit the most kindred to her own; and it is probable that her anxiety to have Henry far distant from the scene of action, arose from a desire to enable the son of her choice to avail himself of any contingency that might occur, in order to usurp the throne during his brother's absence. Concerning the mode and causes of the death of Charles IX., there exists considerable doubt. It is more than suspected, however, that he was poisoned by his brother Francis, with the connivance of his mother, by means of a treatise on hawking which had been thrown in his way, that being a sport of which he was passionately fond, with its leaves gummed together with some poisoned gluten, so that when he moistened his fingers at his lips to disengage the pages, he took in at every touch the deadly medicament. If it were so, it was a lost crime; for, on hearing of the death of his brother the king, Henry, in an evil hour for himself, escaped by stealth from the throne of a country whose people loved him, and came to claim that of a land where he was both hated and despised. On his return, he threw himself wholly into the hands of his mother, who again plunged the country into religious civil wars, in which Henry IV. of Navarre gained all the glory, and Henry of Guise all the power, until the latter, attempting to usurp the sovereign power of the realm, was assassinated by Henry's orders in the royal cabinet, while his brother the cardinal was on the next day murdered in prison. This *coup d'état* is so exactly in keeping with the character and policy of Catharine, and corresponds so closely with her plan for taking off the prince of Condé, in the reign of Francis II., that we can scarcely err in ascribing to her the conception of the scheme. It was the ruin of Henry, of herself, and of all her wishes as to the succession of the crown of France; for, how careless and indifferent soever she might be as to matters of religion, she did not certainly desire that a Huguenot and a Bourbon should ascend the Catholic throne of the Valois. Such, however, was the result of her machinations. The murder of the Guises united all Catholic France against Henry III., and he found that he had now no option or alternative but to call Henry of Navarre to his assistance, and to put down the now rebellious Papists by the forces of the late rebellious Protestants. Henry of Navarre, who was now, by the death of Alençon, the next heir to the throne of France, readily assented, and on bringing up his forces the 2 princes laid siege to Paris, which was defended by the duke de Mayenne, the younger brother of the murdered Guise. But while the siege was pending, Henry III. was himself assassinated by a fanatic monk, Jacques Clement, probably instigated by the Guises, on Aug. 1, 1589, in the camp at St. Cloud. Henry IV. succeeded him, and did much to heal the wounds which had been inflicted on France

by Catharine de' Medici.—See CHARLES FRANCIS II., HENRY III., HENRY IV. and the ST. BARTHOLOMEW MASSACRE.

CATHARINE OF SIENNA, saint, died April 29, 1380. She entered at an early age the order of Dominican nuns. Her remarkable superiority of her natural gifts, joined to her extraordinary graces, rendered her one of the most famous and influential persons of her time. She restored the Florentines to the favor of Gregory XI., and exhorted that pontiff to return to Rome. She took part in the schism of that time, and wrote in defense of Urban. Her zeal for the conversion of the heathens knew no bounds, and the most powerful could not resist her exhortations to a life of piety. Her charity to the poor, and devotion to those who were suffering from the most offensive maladies, were also remarkable. She was canonized by Pius II. in 1462. Her anniversary is celebrated on April 29. Her works of this saint are principally upon devotional subjects, and written in very pure Italian; she is also the author of some Italian poems.

CATHARINE FIESCHI ADORN, born in Genoa, 1447, died Sept. 14, 1510. She was viceroy of Naples. She is said to have been one of those rare children who from an early age practiced the perfect practice of Christian virtue. At the age of 13 she was dedicated to God in the religious life, but she yielded in obedience to her parents, who married her at the age of 16 to Julian, a gay young nobleman of Genoa. Her husband was for 10 years a series of sorrows, and mortifications. He was cruel, brutal, and prodigal in the use of money, which she brought him. In a short time they found themselves reduced to poverty. Her patience and good example caused his conversion, and he died a penitent. After his death Catharine was many years mother superior of the great hospital of Genoa. Practicing the greatest charity, she performed the offices and dressed the most loathsome patients. She also extended her care to the sick and suffering throughout the city. St. Catherine next to St. Theresa, is the most famous female writer that the Roman Catholic Church has produced. Her 2 principal treatises, for the most part may be considered as dictated by the words of her own experience, are entitled "The Book of the Spirit," and "A Spiritual Dialogue." Her works have not hitherto been within the reach of general readers; but an American edition of her treatises and of her life, with her confessor, Marabotto, has just been published (1858).

CATHARINE PARR, the 6th and last relict of Henry VIII. of England, date of birth uncertain, died Sept. 30, 1548. She was the daughter of Sir Thomas Parr, and was first married to Edward Burghe and second to Thomas Latimer. After a 2d widowhood she

king of England married her, July 12, 1547. For the time in which she lived she was very well educated and intellectual and had studied the Holy Scriptures with much attention. She was a zealous partisan, and would often engage in controversy with the king as to the propriety of the reformation. She even patronized Anne Askew, who was racked and burned at the stake in 1546, and perused the prohibited or disputatious turn of mind brought about great peril on one occasion. After one argument on religious subjects with the king, Henry was much incensed at her, and on the instigation of the bishop of Winchester issued a warrant for her committal to prison on the charges of heresy and treason. On receiving immediate intelligence of her danger, she went to the king in the evening, and in conversation to the old topic, expressed her regard for the king's theological views. "No, no, by St. Mary," he replied, "you too well. Ye are a doctor, Kate, instruct us and not to be instructed by us." To which she adroitly rejoined "that it was much mistaken her freedom in trusting to him, since she did it to engage his course, to amuse this painful time of his, and that she might receive profit from his discourse." "And is it even so?" he inquired; "then we are perfect friends." The following morning the king took her to the garden with Catharine, and at that time the chancellor, Wriothesley, who was of the reconciliation, came with a warrant to execute the warrant for the arrest of Anne Askew. The king flew into a passion, and called Wriothesley a knave and other epithets, and the warrant was begone. This experience made Anne more prudent for the future; yet her courage was again great when Anne Askew was brought in order to ascertain her accomplices in the queen of heresy, but the attitude of the sufferer was the salvation of the royal patroness. She retained her place in the king's affections up to the time of his death in 1547, and received a legacy of money from him in addition to her jointure. After the king's death she was married to Thomas Seymour, high admiral and brother of the duke of Somerset, protector of England and guardian of the young Edward VI. She did not long survive this marriage, dying in childbirth unregretted by her husband, who repented of his union with Catharine. She is one of those women who have won a position in the history of letters. She wrote "Queen Catharine Parr's Lamentations of a Sinner," published by Lord Burleigh in 1548. In 1549 she published a volume of spiritual meditations. Her letters are preserved in Strype's annals, Hayne's collection of letters, and in the Ashmole collection. They have been translated by several scholars to translate from the

Latin into English Erasmus's paraphrase on the New Testament, and wrote a Latin letter to the princess, afterward Queen Mary, exhorting her to translate the paraphrase on St. John.

CATHARINE PAULOWNA, queen of Württemberg, grand princess of Russia, daughter of Paul I. and younger sister of Alexander I., born May 21, 1788, died Jan. 9, 1819. In 1809 she married George, duke of Holstein Oldenburg. Having lost him in 1812, she accompanied her brother Alexander on his campaigns in Germany and France (1818-'14), to Paris, London, and the congress of Vienna (1815), assisting him by her talents and resolute spirit. The marriage of her younger sister to the prince of Orange is said to have been effected by her influence. In 1816 she married William, crown prince of Württemberg, whose acquaintance she had made during her travels. During the famine of 1816 in that country she proved her benevolence by the formation of female associations and an agricultural society. She was active in promoting the education of the people. She left 2 sons by her 1st, and 2 daughters by her 2d marriage.

CATHARISTS (Gr. *katharoi*, pure), a Christian sect which, between the 11th and 14th centuries, spread over all Europe, and was most powerful in Italy and the south of France. Their doctrines and institutions bore an oriental impress, but were peculiarly elaborated and modified by the scientific spirit of the western church. Akin to the early Gnostics, the Manichæans, Euchites, Bogomiles, Paulicians, Albigenses, and Waldenses, they are not to be confounded with either of these. There were 2 parties of Catharists, one accepting absolute dualism, and supposing 2 opposite principles to subsist from all eternity, with 2 creations corresponding to these principles; the other deriving all evil and imperfection from the apostasy of a higher spirit, and maintaining a limited dualism. They agreed in regarding the sidereal system, and every thing visible here below, as perishable and evil; but as having its correspondent in an upper world in a form adapted to that higher region of existence. According to one party the evil principle stole into the heavenly world and seduced the souls which the good principle had created to come down to earth, where he confined them in bodies of his own creation. According to the other party, the orderer of matter was originally a good but now a fallen spirit, who, ambitious to set up an independent kingdom of his own, persuaded a third part of the angels to apostatize with him. The former held that there have never been more souls on the earth than on the first day after they were misled thither by Satan, and that by process of transmigration and return to heaven their number is constantly diminishing; the latter supposed originally only 2 human souls, from which all others have proceeded. Both parties rejected the whole, or nearly the whole, of the Old Testament, which they affirmed to be a revelation of the evil principle. Christ, they

thought, brought with him from the celestial regions a higher ethereal body. He was sent by God to recover men from the earthly sphere in which they are bound, and to bring them into harmonious connection with the upper world; and the final result of his coming will be the destruction of the creation produced by Satan, and the return of all visible things to the original chaos, to which wicked spirits shall be banished.—The ideas of the Catharists were rather popular than metaphysical, and the sect was more influential by the ethical than by the speculative part of its system. They all agreed in opposing the prevalent traditional and ceremonial usages, and attempted to realize the idea of an invisible church. They renounced baptism by water, and laid great stress on the baptism of the spirit, which should be performed by the imposition of hands in connection with prayer. Their church edifices had neither images, cross, nor bell, and their worship consisted only of the reading and exposition of a passage of the New Testament, followed by the benediction, which was received kneeling. Though, in some respects, the precursors of the Protestant principle, they were yet essentially removed from it by the merit which they ascribed to works over faith as a condition of salvation. Their rigid asceticism admitted neither of animal food, conjugal relations, nor the possession of earthly goods. Yet this standard was rather ideal than actual. It was attained by the *perfecti*, the esoterics of the sect, but was modified in the case of the *credentes*, who constituted the large exoteric portion. From the former, who were popularly known as "the good men," and who copied the example of Christ by wandering about homeless, and in poverty, were chosen all the officers of the sect.—The Catharists were zealous disseminators of their principles. Originating in some Greek-Slavonian cloister of Bulgaria (whence one of their names, the Bulgarians), they prevailed for several centuries in the western countries of Europe, maintaining themselves in Bosnia in spite of hostility, till near the close of the 15th century, when the sect passed over into Mohammedanism. In 1035 the first Catharists were discovered in Italy, near Turin, and their chief was burned; but within a century from that time Catharist churches and dioceses were formed throughout upper Italy and France. It has been maintained, without sufficient authority, that Dante belonged to the sect, was even a preacher to a congregation of Catharists at Florence, and that the *Divina Commedia* was a pasquinade in their favor against the prevalent church. St. Bernard travelled through the country south of the Alps, trying in vain to convert them, and found them protected by princes and nobles, whose sons and daughters were intrusted to them for education. In 1167 they held a synod near Toulouse to arrange uniformity of policy and doctrine. They spread throughout Spain and Germany, but though some of them were discovered in London in 1210, they seem to

have made little progress in England. They availed themselves of the disputes between the popes and emperors to spread their doctrine, and in the 12th century dared to elect for themselves a pope in France, and in the 13th century another in Bulgaria. In later times the knights templars were asserted to have been Catharists. The courage and calmness with which they uniformly met death for their faith, excited the admiration of their friends, and was attributed, by their enemies, to diabolical support.

**CATHARPINGS**, in nautical parlance, ropes serving to brace in the shrouds of the lower masts behind their respective yards.

**CATHCART**. I. **WILLIAM SHAW**, earl, a British military officer and diplomatist, born in 1774, died June 17, 1843. According to a custom of the Scottish gentry, he completed his education by taking a degree in law, although without intention of practising that profession. On the breaking out of the American war he entered the British army, and speedily rose to be aide-de-camp to Gen. Spencer Wilson and Sir Henry Clinton. Subsequently he commanded the 29th regiment of infantry, and finally was appointed quartermaster general. Recalled to England, he joined the Walcheren expedition with the rank of brigadier-general. Having distinguished himself at Bommel and elsewhere on the retreat, he carried back the remains of the cavalry to England, where he was promoted to a higher rank. In 1807 he took his seat as a representative peer of Scotland. The same year he was appointed commander-in-chief of the troops destined to act against Copenhagen, and on the fall of that city and capture of the Danish fleet was created a peer of England. In 1812 he was sent as minister plenipotentiary to Russia. The emperor Alexander being then with the army, Lord Cathcart joined him at head-quarters, where he remained during the campaign. He was a witness of the interview between the sovereigns of Russia, Austria, and Prussia; at Dresden he stood but 2 paces from Napoleon when that general received his death wound; entered Paris with the allied sovereigns, and subsequently acted as British plenipotentiary in the congress of Vienna. On the fall of Bonaparte he again repaired to Paris, and signed the treaty of peace which followed Waterloo. An earl's coronet recompensed these services. Several succeeding years of his life were spent as minister at the court of Russia. II. **SIR GEORGE**, a British general, son of the preceding, born in London, May 12, 1794, died Nov. 5, 1854. He was educated at Eton and Edinburgh, and entered the army in 1813. His father having been soon afterward appointed minister to Russia, young Cathcart accompanied him as attaché, and was subsequently his secretary at the congress of Vienna. Rejoining the army, he served as aide-de-camp to Wellington at Waterloo. The return of peace placed him on the list of lieutenant-colonels, in which rank he held commands for some years in Nova

Scotia and the West Indies. In 1834 he retired on half pay, but in 1837, in consequence of the troubles in Canada, he was placed in command of the troops and militia south of the St. Lawrence. Returning to England in 1844, he again retired on half pay, receiving the honorary appointment of governor of the tower of London, which he retained until 1852. War with the Caffres having once more broken out, Col. Cathcart was selected to assume the governorship and command of the army at the Cape of Good Hope. By a succession of well-executed manoeuvres, he drove the Caffres back from their coverts, and removed them beyond the limits of the colony. Appointed to the 4th division of the army in the Crimea, he fell fighting gallantly at the battle of Inkermann.

**CATHEDRAL** (Lat. *cathedra*, a seat), a church containing a bishop's throne or seat, the chief church of the diocese. Its usual form is a Latin or Greek cross, and it is not distinguished architecturally from the basilica. In the old basilicas there was a transverse hall at the end, not intentionally resembling a cross; but more modern architects, perceiving the resemblance, changed the position of the transept, making the church cruciform. The church of St. John of Lateran, at Rome, founded by Constantine, is the episcopal church or cathedral of the pope, and bears over its chief portal the inscription, *Omnium urbis et orbis ecclesiarum mater et caput*, "mother and head of all the churches of Rome and the world." At its chief altar none but the pope can read mass, for it covers another ancient altar at which the apostle Peter is said to have officiated. The basilica of St. Peter's at Rome may be mentioned as surpassed by no cathedral in antiquity and splendor, and equalled by none in magnitude. In A. D. 90, St. Anacletus, bishop of Rome, who was ordained by St. Peter himself, erected an oratory on the site of the apostle's burial, after his crucifixion. In 306 Constantine built a basilica on the spot. In 1450 Nicholas V. commenced a building on plans of Bernardino and others. Paul II. continued it, and Julius II. secured the services of Bramante, whose plan was a Latin cross and an immense dome on arches springing from 4 large pillars. The latter died in 1514, and Leo X. appointed Giuliano Sangallo, Giovanni da Verona, and Raphael, who strengthened the pillars for the dome; but Sangallo dying in 1517, and Raphael in 1520, Leo employed Baldassari Peruzzi, who changed the plan to a Greek cross. Paul III. employed Antonio Sangallo, who returned to Bramante's plan, but Sangallo died very shortly, and the pope appointed Giulio Romano, who also died. The work was then given to Michel Angelo, then in his 72d year. Paul III. died in 1549, but Julius III. continued Angelo in his place, giving him full authority to change whatever he wished in the building as it then stood. Michel Angelo returned to the Greek cross, again strengthened the piers

for supporting the dome, and formed the plan for it as it now exists. The drum of the dome was completed before he died in 1563. Pope Pius V. appointed Vignola and Pirro, with orders that they should adhere to Angelo's plans. The dome was not finished until 1590 by Giacomo della Porta. Sixtus V. gave 100,000 gold crowns annually toward its completion. In 1605 Paul V. employed Carlo Maderno, who changed the ground plan back to the Latin cross. The nave was finished in 1612, the façade and portico in 1614. The church was dedicated by Pope Urban VIII. on Nov. 18, 1626. Under Alexander VII. in 1667, Bernini finished the colonnade. The building of St. Peter's, from its foundation in 1450 until its dedication, occupied 175 years; and if we include the work done under Pius VI., 8½ centuries passed away before it was completed, during which time 43 popes reigned and died. The dimensions of the church are as follows: length of the interior 602 English ft., length of transept from wall to wall 445 ft.; height of nave 150 ft., of side aisles 47 ft.; width of nave 77—89 ft., of side aisles 21 ft.; circumference of pillars which support the dome 282 ft. The cupola is 198 ft. in diameter. The height of the dome from the pavement to the base of the lantern is 400 ft., to the top of the cross 480 ft. The dome is encircled and strengthened by 6 bands of iron. A stairway leads to the roof, broad and easy enough to allow a loaded horse to ascend. The annual cost of keeping the church in repair is 80,000 scudi.—At Milan the first building was destroyed by Attila, the next one was injured by fire, and the first stone of the present structure was laid by Giovanni Galeazzo Visconti on March 15, 1386. The ground plan is a Latin cross terminated by an apsis. Its dimensions are: length 485 ft.; breadth of body 252 ft., between the walls of the transept 287 ft.; width of nave from centre to centre of the columns 67 ft., which is double the width of the side aisles; height of the crown of the vaulting of nave 158 ft.; height from the pavement to top of the statue of Madonna 255 ft. The interior is divided into a nave and 4 aisles, by 4 ranges of clustered pillars. Fifty-two pillars, each formed of 8 shafts, support the arches of the roof. These pillars are 80 feet high, i. e. base 4 ft., shaft 57 ft. 6½ in., capital 18 ft. 6½ in.; the diameter of shaft 8 ft. There are fine interior doorways in Roman style. The pavement is laid in mosaic in red, blue, and white marble. The cathedral is built of white marble, and covers a space of 107,782 sq. ft.—The duomo at Florence is one of the most beautiful specimens of the Italian-Gothic style. It was begun in 1294 or 1298, with the plan, according to Vasari, of Arnolfo di Lapo, according to Molini, of Arnolfo di Cambio da Oalle, and was finished about 1444. Several architects were employed upon it, among them Giotto, Taddeo Gaddi, and Andrea Orgagna. Its completion was intrusted to Brunelleschi, who designed

the cupola. The cathedral is in length 387 ft., the transept 334 ft.; the nave is 158 ft. high, the side aisles 96 ft. 6 in. The cupola is octagonal in form, 136 ft. 6 in. in diameter, and in height from cornice of the drum to the eye of the dome 133 ft. 6 in. Michel Angelo used this dome as a model for that of St. Peter's. The interior of the duomo is rather dark, the windows being small and the glass darkly stained. The pavement is tessellated in red, blue, and white marble. The frescoes in the cupola are from designs by Vasari. The entire edifice covers 84,802 sq. ft.—Germany has some fine cathedral churches, among which that at Cologne is one of the most imposing Gothic structures in Europe. It was begun in 1248, during the reign of the elector and archbishop of Cologne, Conrad of Hochstedten, but it has remained unfinished. The original architect is unknown. The length of the cathedral is 511 ft., breadth 231 ft., and height of the towers 500 ft. Externally it has a double range of flying buttresses and intervening piers, and a perfect forest of pinnacles. The cathedral of Dantzic was begun in 1343 and finished in 1503. The vaulted roof is 98 ft. above the pavement, supported by 26 slender brick pillars. Around the interior are 50 chapels founded by the chief citizens of the place, as burial places for their families. The great ornament of this building is a painting of the "Last Judgment," attributed to John Van Eyck. It was painted for the pope, but on its way was captured by pirates. Being retaken by a Dantzic vessel, it was deposited in the cathedral in 1807.—In Antwerp is the cathedral of Notre Dame, one of the largest and most beautiful of Gothic buildings in the Netherlands. It was commenced about the middle of the 13th century, and completed in about 84 years. It is 500 feet long, and 250 wide. In 1583 it was much injured by fire. It contains the celebrated masterpiece of Rubens, the "Descent from the Cross."—During the 13th century, architectural art was highly cultivated throughout all Europe, and among the magnificent works of that age, those of France are by no means in the last rank. Chartres, Rheims, Amiens, and Paris each possess beautiful cathedral churches. The one at Rheims was commenced in 1211, and dedicated in 1241. It occupies 67,475 sq. ft. The cathedral at Amiens was begun 1220, and completed in 1257, but was partially destroyed by fire, and not again finished until 1272. It covers 71,208 sq. ft. The cathedral of Notre Dame in Paris stands upon the spot once occupied by a Roman temple. It is said that a church dedicated to St. Stephen was erected on the same site about 365, in the time of Valentinian I., and was enlarged in 522 by Childebert, son of Clovis. Robert, son of Hugh Capet, undertook to rebuild this church, which was called Notre Dame from a chapel which Childebert had dedicated to the Virgin. But this church was never finished and fell into ruins. The first stone of the present edifice was laid about 1163, by Pope Alexander III., Maurice de Saliao being bishop of the

diocese. The high altar was consecrated in 1185 by Henry, legate of the holy see, and in 1185 Heraclitus, patriarch of Jerusalem, officiated in the church. The west front was finished by Maurice de Sully, the bishop in 1222. The southern transept with its portal was completed in 1257, and the northern transept and portal in 1312 by Philip the Fair. The western doors with their iron work were made about 1570-'80 by Biscourette. The dimensions are as follows: length 390 ft., width of transept 144 ft., height of vaulting 102 ft., height of western towers 204 ft., width of front 128 ft., length of nave to transept 186 ft. The pillars of the nave are 4 ft. in diameter, resting on gravelled bed 18 ft. below the surface. The style of architecture is pure pointed. The nave and side aisles are paved with marble; the aisles around the choir are paved with stone and black marble. An immense vault, extending the entire length of the nave, was constructed in 1666 for the interment of the chaplains, &c. The organ is very fine, 45 ft. high, 36 in breadth, and has 3,484 pipes. The interior of Notre Dame is not so rich in decorations as the exterior. The arches of the nave are pointed; the piers are circular pillars, with large and well-formed capitals. The pillars of the aisles are alternately circular and clustered. The cathedral covers 64,166 sq. ft.—England has many cathedrals worthy of particular mention. That at Salisbury is the most perfect and beautiful specimen. It was founded by Bishop Richard Poore, in the year 1220, in the reign of Henry III., and was finished in 1260. Its plan is a double cross, in extreme length outside 480 ft., length of transept 222 ft.—St. Paul's, London, was commenced in 1675, Sir Christopher Wren being the architect, and was finished 1711. It is built of fine Portland stone, in the form of a Latin cross, in length being 500 ft., the transept 205 ft. long, and the west front 180 ft. wide. The towers at the west front campanile are each 222 feet high. The dome is thrice the height of the roof, being 365 ft. from the ground, and 255 from the floor of the church, and it is 145 ft. in diameter. Simple ratios exist between the principal dimensions. The windows are mainly 12 ft. wide by 24 high, the aisles 19 ft. clear width by 38 in height; the central avenue is 41 by 84 ft.; the domed vestibule at the west end is 47 ft. square by 94 ft. high. The architectural elevation has two orders, the lower being Corinthian and the upper composite. The interior lacks in ornament, disappointing one who has seen the cathedrals on the continent. A still graver defect is the darkness under the dome, the light being scantily admitted and not well distributed. It was begun and finished under one architect, with a few mean exceptions. The organ was built in 1684 by Bernard Smydt. St. Paul's is the 5th cathedral of Europe in extent, being smaller than St. Peter's, and the duomos at Florence, Milan, and Amiens.—The corner stone of a new and magnificent cathedral was laid in New York, Aug. 15, 1886.

**CATHELINEAU, JACQUES**, generalissimo of the peasants in the revolt of 1793 against the monarchical government of France, born at Saumur, Maine et Loire, Jan. 5, 1759, died at St. Florent, July 14, 1793. After having engaged for some time in the business of a linen draper, who was a mason, he became a linen draper, and after the outbreak of the French Revolution, was poor and embarrassed with the support of a large family. His religious devotion was great, and so well known in his province, that he was called the saint of Anjou. A bloody battle took place at St. Florent, March 1793, between the republican troops and the royalists, on the occasion of a levy for the army according to a recent decree of the convention, in which the spirit of Cathelineau, and at the head of a band of youths he attacked and expelled the royalist garrisons of Jallais and Chollet. As the valor and courage of his bands, though without regular arms, were continually increasing, he won several engagements, mostly with the royalists.

After the taking of Saumur (June 18), the want of greater union in the operations of the agents being generally felt, Cathelineau was elevated to the dignity of general-in-chief, the most popular of the leaders. He marched on Angers, which made no resistance; but on Nantes, though undertaken at the head of a large collected army, and though there were no fortifications, and was defended only by a regiment of the line, ended, after a day of desperate struggle (June 29), in the dispersion of his troops. At a last and unsuccessful effort to take the city, Cathelineau was wounded and carried to St. Florent, where he lived for a fortnight. After the restoration of the Bourbons, his surviving children were rewarded with pensions, and a statue was erected to his memory at his birthplace, which was taken in 1832 by the soldiers of Louis XVIII.—One of his sons, who in 1815 took part in an anti-Napoleonic movement of the Vendée, was shot in 1832 while engaged in the piracy of the duchess of Berry.

**CATHELINOT, CATELINOT, or ILDEFONSE**, a Cistercian monk, born in Paris in 1670, died at Paris, June 15, 1756. He was destined for the pulpit, but devoted himself at the abbey of St. Denis, under the instructions of Calmet, a co-laborer he afterward was, to literary studies. He wrote a Bible dictionary, and also edited the supplement of Calmet's, which has alone been published of all his numerous works.

**CATHODE** (Gr. *κατα*, downward, and *ὁδος*, way). The poles of the battery were called by Faraday electrodes. To the one which is supposed to receive the electric current, and is therefore called negative, he gave the name cathode; and to the other, which is supposed to flow over with electricity and to be consequently in a positive state, the name anode was given. In the wires proceeding from the battery, the electric current is supposed to pass from the zinc plate, round to the

zinc plate; and the term poles is applied to the ends made by a break in this wire. As the electricity flows from that connected with the copper, this is the positive electrode, or the anode; while the opposite pole leading to the zinc plate receives the current, and is the negative pole, or the cathode. But in the battery itself, the electricity being supposed to be generated at the zinc plate, this is called the anode or positive pole or plate, and the copper the negative. The significance of the terms introduced by Prof. Faraday is explained by his supposing the wires of the battery to be so arranged, that the electric current passing through a body interposed between the poles traverses from E. to W. parallel with the currents supposed to be flowing through the earth. The anode in this arrangement is toward the E. or rising sun, and the cathode toward the setting sun. See **ELECTRODYNAMICS**.

**CATHOLIC CHURCH.** See **ROMAN CATHOLIC CHURCH**.

**CATILINE, or CATILINA, LUCIUS SERGIIUS**, a Roman conspirator, killed in the engagement of Fesulæ, 62 B.C. He was the descendant of an ancient but decayed patrician family, and spent his youth and early manhood in a career of profligacy and crime, taking a bloody part in the proscriptions of Sylla, when even some of his own relations became his victims. He was suspected of criminal intercourse with a vestal, and believed guilty of the secret murder of his first wife and his son, committed in order to marry another woman. All this did not prevent him, at that period of moral decline and general corruption, from obtaining important offices and aspiring to the highest dignities in the republic, being able by his mental and bodily powers, of which even his enemies speak with a kind of admiration, to undertake every task. Having been sent as prætor to Africa, he returned in 66 B. C. to Rome, to become a candidate in the next consular election, but was disqualified by a charge of extortion in his province, directed against him by Clodius Pulcher, known by his later enmity to Cicero. The newly elected consuls were convicted of bribery, and Cotta and Torquatus, their accusers and competitors, took their places. On these the disappointed Catiline resolved to wreak his vengeance, conspiring against their lives with Autronius, one of the deposed consuls, with Cn. Piso, and others. The first day of the consulship was fixed for the assassination, but Catiline frustrated the attempt by his impatient haste in giving the signal. This failure only served to exasperate Catiline, and to stimulate him to greater undertakings. Ruined by debt and debauchery, he was now bent on forming a new conspiracy with the purpose of exterminating the whole body of the senate, murdering all the magistrates of the republic, and sharing its sway and treasures with his followers. Such at least is the representation of great contemporary writers, whose impartiality, however, may be questioned. The corruption of the times favored his

designs; ruined nobles of all ranks, eager to escape by some change the consequences of bankruptcy, profligates and intriguing persons of both sexes, joined him; many veterans of Sylla, who had squandered their spoils, were found ready to renew the familiar scenes of proscription; the poor and restless populace could easily be used. His chief coöperators were P. C. Lentulus and P. Autronius, ex-consuls, L. Calpurnius Bestia, tribune elect, Cethegus, 2 nephews of Sylla, and others. It was now his interest to be elected consul; he became a candidate, but was again unsuccessful. Cicero was elected with C. Antonius. Catiline, who dreaded the patriotic activity of the former, but counted on the criminal connivance of the latter, now pushed on with greater vigor. The plot was matured; troops were levied, especially under C. Manlius, a centurion of Sylla, in the vicinity of Fæsulæ, in Etruria; arms were provided, the parts of the drama distributed, the lists of proscription made out, and the day fixed for the assassination of the consuls and the general conflagration of the city. The watchfulness of Cicero saved himself and the republic. Fulvia, the mistress of one of the conspirators, was induced to communicate all the particulars; C. Antonius was made harmless by the promise of Macedonia as a province. Informed by Cicero, the senate intrusted the consuls with absolute power to save the republic from the threatening danger. At the following consular election Catiline was again rejected, and in the night of Nov. 6, 68 B. C., he declared in a secret meeting to his ringleaders that the time of action had arrived. Cicero, who knew every thing, summoned the senate, and delivered his first great oration against Catiline, giving full and ample information of all the facts. Catiline was bold enough to be present and to attempt his justification, but his voice was drowned by the cries of "Enemy" and "Parricide" from the indignant senators, and he was left on his deserted bench a spectacle to the assembly. But he was still free, and left Rome in the following night to join the camp of Manlius, leaving the management of affairs at the capital to Lentulus and Cethegus. Cicero now addressed the people in the forum, justifying his conduct; the senate declared Catiline and Manlius enemies of the republic, while legal evidence against the conspirators at Rome was furnished by the communications of the ambassadors of the Allobroges, who, being sent to Rome for the redress of grievances, were tempted by Lentulus to join the conspiracy, and to induce their nation to assist in it. Cicero, who received the intimation from their patron, persuaded them to feign an active participation, and to draw from Lentulus a list of the conspirators, as if by it to induce their countrymen to join in the enterprise. Lentulus and his friends fell into the snare. They were now brought before the senate, assembled in the temple of Concord (Dec. 4); their guilt was proved. Having delivered his third oration

before the people. He again convoked the senate for the punishment of the conspirators. Silanus, then highly animated, gave his opinion for the immediate execution of them; this was opposed by Julius Cæsar, who was satisfied with the confiscation of their property, and the dangers of the state. Cicero, however, and for immediate efforts: he went into the field, made an appeal to the senate, and prevailed. The law was passed, and Lentulus and his co-conspirators were strangled in the night in their own houses. A law was sent against Catiline and Cethegus, but unwilling to be taken, he gave the command to his troops. They met near Fæsulæ. Catiline fought himself desperately, but the battle was lost he threw himself off his enemies, and fell. The discovery of the conspiracy, is equalled by the success of the operations against Catiline. A list of the conspirators is one of the productions of ancient history.

**CATINAT DE LA FAMILLE AUCONNERIE**, François DE, a French general, born in Paris, Sept. 1, 1687, died Feb. 22, 1712. He entered the army as an ensign, and at the siege of Lille in 1667, so conducted himself as to attract the notice of Louis XIV. His subsequent exploits obtained for him in 1688 the rank of lieutenant-general, and in 1693, after he had conquered the greatest part of Savoy, he received the marshal's staff. In 1701 he commanded the army in Italy against Prince Eugene, but failing to arrest the progress of the prince, Villeroy was appointed to his place, and Catinat served under him, and in attacking the intrenchments at Chiari he was repulsed and wounded. He commanded in Germany for a short time, and spent the rest of his life at his estate of St. Gratien, near St. Denis.

**CATINEAU-LAROCHE, PIERRE MARIE ST-BASTIEN**, a French functionary and lexicographer, born at Saint-Brieuc, March 25, 1772, died May 22, 1828. He studied at Poitiers, and emigrated to St. Domingo, where he published a journal, *L'ami de la paix et de l'union*. He was sentenced to death for the opinions which he advocated, but, by the timely assistance of the agents of the king of France, succeeded in escaping to Cape Haytien (then called Cape François), where he alone, of 17 of his countrymen, was saved from the massacre which broke out in that city. He now visited the United States and England, and on his return to Paris, in 1797, composed several dictionaries. His printing office having been destroyed by fire, the government employed him in various public capacities. Once more he visited the United States, and on his return, in 1819, he was commissioned to go to Guiana, and study the lit-

mate and resources of that province. His notes on that country appeared in 1822.

**CATIONS**, electro-positive bodies, as hydrogen, the metals, &c., those which go to the cathode or negative pole of the battery, or are found on the positive side of the electrolyte. (See **CATHODE**, **ELECTRODYNAMICS**.) **Anions** is the name of the electro-negative bodies, or those which go to the anode or positive pole.

**CATLIN**, **GEORGE**, an American artist known by his travels and residence among the Indian tribes of the west, was born in Wyoming Valley, Penn. His father was a lawyer, and George studied law in Connecticut, and practised for 2 years. Afterward he devoted himself to painting in Philadelphia, without any previous instruction. Some Indians arriving on a delegation in the city, he was struck with their appearance, and determining to visit their homes, he started from St. Louis in 1832, in a steamer called the "Yellowstone," being greatly assisted by Mr. Chouteau, one of the owners of the boat. After a passage of 8 months, he reached the mouth of the Yellowstone river, where he was left. He visited about 48 tribes, numbering in the aggregate 400,000 souls, and collected much information concerning their habits and character. He also visited Florida and Arkansas. His letters were published in 2 vols. 8vo, with illustrations (New York, 1841).

**CATMANDOO**, or **KHATMANDOO**, a town of Nepaul, regarded as the capital of that country, on the E. bank of the Bishnumutty river, 137 m. from Goruckpoor, 53 from Gorkha; lat.  $27^{\circ} 42' N.$ , long.  $85^{\circ} 18' E.$ ; pop. about 50,000. The streets are narrow, and the houses (of which there are about 5,000) present a mean appearance, not excepting that of the rajah, and are built of brick, though building stone abounds. Many of the temples, most of which are of wood, are of considerable elevation, and scattered in great numbers over the environs of the town. There are several temples of singularly picturesque appearance. An ancient temple, dedicated to Buddha, built of stone, consisting of 3 lofty pyramids with 2 square apartments, is much celebrated among the Tartars, and a great resort of pilgrims.

**CATNIP**, or **CATMINT**, the leaves of a perennial herbaceous plant, *nepeta cataria*, which is very common in the fields throughout the United States, though supposed to have been introduced from Europe. The plant possesses medicinal virtues, so that it is recognized in the pharmacopœias, and is employed as a domestic remedy, but rarely, however, in regular practice. The leaves, which alone are used, are aromatic and somewhat bitter and pungent to the taste, and of disagreeable odor. Cats are said to eat them with great relish, and the general impression is that they derive benefit from their medicinal qualities. Catnip is administered in infusion. It acts as a tonic and excitant, and possibly as an antispasmodic and emmenagogue, being frequently given with

reference to such supposed qualities. Toothache is said to be sometimes cured by chewing the leaves.

**CATO**, the name of a celebrated family of the great Porcian house of Rome, several members of which attained high distinction as statesmen, writers, and soldiers; but none so conspicuously or deservedly as the two respectively known as **CENSORIUS** and **UTICENSIS**, both of which names were posthumous, not given by their contemporaries. **I. MARCUS PORCIUS CATO**, surnamed the Censor, and the Elder, was a native of Tusculum; his family was plebeian and poor, nor had acquired any note until the actions of this man gave to it nobility and renown. His birth bears date from the year 284 B. C., and at his father's death he inherited a small farm and cottage in the Sabine country, closely adjoining a similar estate of the patriotic and rustic Marcus Curius Dentatus, with whom he was on terms of intimacy from his early youth, and probably from him he copied some of that austerity of character and carelessness of the graces of life for which he afterward became famous. In 219 B. C. began the second Punic war, which may be regarded as a 17 years' duel between Hannibal and Rome. This called out the young plebeian, at the earliest age at which it was admissible to bear arms, that is to say in his 17th year, from his Sabine farm to the service of his country. The battle of Cannæ, fought on its own territory, within comparatively a few miles of its gates, was the greatest defeat and disaster which a sovereign city ever underwent without succumbing to the victor. But Rome was only the sterner and more steadfast after her unparalleled defeat, and was nerved only to greater exertion by her loss. In the year following the battle, the same in which Cato first buckled on his armor, the city of Rome, out of a population which, at the last military census, had numbered only in all 270,213 citizens, had 70,000 soldiers, beside seamen, under arms, or something above  $\frac{1}{2}$  part of all her male inhabitants. Fabius Maximus was dictator, and under him Cato first saw service at the siege of Capua. During the whole of the 2d Punic war, he was actively employed, and five years later was present, under the same general, at the taking of Tarentum; on which occasion he is said to have formed his first acquaintance with Nearchus, the Pythagorean philosopher, from whom he learned the principles and tenets of a system, the practices of which he had adopted long before. After the termination of the war, he was induced by the representations of a rich Roman, Valerius Flaccus, who had property in the same neighborhood, to abandon his farm, on which he had hitherto lived among his slaves, laboring at their head by day, and at sunset feeding at the same board with them on the coarsest fare, practicing the severest austerity, and priding himself on the rude simplicity which he mistook for the essence, instead of one of the external

was accompanied on his return to the capital of the republic. In 195 B. C. he was elected consul, together with his friend Valerius Flaccus, and made himself notorious rather than famous by his violent opposition to the repeal of the Oppian law, a sumptuary enactment restricting the expenses of women, which had been passed during the public distresses caused by Hannibal's occupation of Italy, and which had served the purpose for which it was intended, and was now properly rescinded. On the expiration of his consular term, during which he conducted a war which had broken out in some revolted districts of Spain to a successful close, and obtained a triumph for his conduct in the same, although not without being accused of perfidy and cruelty, he followed Sempronius, the consul of the ensuing year, into Thrace, where the war against Philip II. of Macedon was yet in progress, in quality of his lieutenant. Three years later than this, the war against Antiochus broke out, and he was employed in forcing the passes of Thermopylae under

that in which one has himself lived, all cases acquitted; but the number of accusations against him shows the aggressive character of his policy of constant civil warfare in which the most considerable citizens of Rome were against the natural justice of the last public employment, the reconciliation of Jugurtha and King Numidius, which he adopted his settled idea of destroying the rival republic that day forth it became his habit, the question was in debate before he was voting on it, in the affirmative, to add the words: "I vote that Carthage be destroyed." He died in place about 149 B. C. His severe economy of Cato resembled that of the French Republic connected with a revolution and a republic on and so on of the

consists merely of a series of dry use of farmers, expressed with, and without systematic arrangement. The best edition of it is contained in *Rusticæ Scriptores*. He left a hundred orations, extant, although neglected in Cicero's time; a work on military some of which is incorporated into that of Vegetius; 7 books of history, entitled *Origines*, which have perished; beside a book of epistles, a book of apophthegms, and a book of morals. Cato appears to have been a stern, headed, obstinate, nearly one-ideaed man, with a strong sense of duty, and a strong conviction of what was right, accompanied with a determination to understand that any thing could be done which coincided exactly with his own views. He had no refinement, and therefore would, if he could, have prevented the progress of luxury, both of mind and body. His sense of corruption growing with the decay of the state; and therefore, hating corruption, seeing no other mode of arresting its progress, would have arrested all progress. PORCIUS CATO, the son of the prætor, his first wife, distinguished himself in the battle of Pydna, against Perseus, king of Macedon, under Paulus Æmilius, prætor. Tertius, he subsequently married a few years afterward, while prætor. III. PORCIUS CATO SALONINIANUS, the second son of the censor Marcus, and wife, who was the daughter of Marcus. This man had been his secretary, and was still attached to his household when his marriage took place. He, like his father, was a stern man. Marcus, died while in the exercise of prætor, leaving one son. IV. PORCIUS CATO, who was elected consul, with Quintus Marcius Rex, in the year 117 B. C., and died while in office. He is remarkable after his death only, and was the father of the most famous of the Cato lineage, surnamed Uticensis. V. PORCIUS CATO, surnamed Uticensis, the youngest son of his death, born 95 B. C., died in the great-grandson of the censor. At his birth he lost both his parents, and was educated by Livius Drusus, his maternal uncle. It is told that on one occasion, his maternal uncle being in the habit of taking a boy, to visit at the house of his father, Cato took notice of the conscriptions going on, and he asked his tutor for a sword to slay the tyrant. The first public appearance of Cato was on the occasion of an attempt of the tribunes to remove a certain pillar from the Curian basilica, which was in the way of the temple. Cato resisted, with the eloquence peculiar to his house, a motion which led to the pride of his family, since the temple had been erected by his grandfather, the censor. Of the further progress of the question we are not informed, but

it appears that the young Cato prevailed, and that his ancestor's column was retained, to the discomfiture of the tribunes. His first military command was that of tribune of the soldiers in Macedon; but he had served as a private legionary in the campaign against Spartacus, in which his half-brother Cæpio was a tribune, and had been offered a prize of valor by Gallus the prætor, which he declined. During his service in Macedon he was summoned to Ænos in Thrace to attend the deathbed of his half-brother Cæpio, to whom he was fondly attached; and after the expiration of his military term, he travelled in Asia, whence he brought back with him Athenodorus, the Stoic philosopher, having adopted the tenets of that school, and pushed its practices to the extreme of their austerity. He was elected city quæstor after his return, and conducted himself with integrity so unusual in that office of responsibility in that corrupt age, that on the close of his term of service, the people escorted him home in a sort of civic triumph. At this time he had obtained credit for such uncompromising and austere morality, that it is related of him that, during the celebration of the feast of Flora, the most licentious of all the Roman festivals, the people hesitated to call on the female dancers, as was usual at a certain stage of the proceedings, to throw off their tunics and dance naked, until Cato should have left the circus. This fact, related by Valerius Maximus, whether true or not, is equally conclusive and characteristic of the received opinion of the man. In the conspiracy of Catiline, Cato strongly supported the aristocratic and conservative party of the state, against the conspirators. He earnestly promoted the election of Cicero as consul, at that crisis, and when elected sustained him with all his accustomed weight and power. After the flight of Catiline himself, and the arrest of the other conspirators, when Caius Julius Cæsar had spoken so eloquently and plausibly against the capital punishment of the traitors, which undoubtedly was forbidden by the Porcian and Valerian laws, as to bring over M. Junius Silanus, the consul elect, and many other leading senators to his opinion, it was Cato who, by a speech the tenor of which and its general argument, if not its actual wording, are preserved in Sallust's history of the conspiracy, confirmed the determination of the senate, and procured the death of the men, not as citizens but as enemies of the state and parricides of the republic. It certainly appears that the crisis justified the means adopted to suppress it, and that had less vigorous measures been taken, it would have been too late to punish when the crimes could no longer be prevented. He was the first who, on the suppression of the plot, hailed Cicero as "father of his country." On the usurpation of what is usually called the first triumvirate, that of Crassus, Pompey, and Cæsar, being opposed to their proceedings, he was sent into a sort of honorable exile as governor of the island of Cyprus, and at the end of his service paid

as Cato did expect, they were completely defeated, and the relics of their army which escaped from the field were so entirely dispirited that they refused to defend the city. On perceiving the impossibility of holding out, Cato now sent off all his friends by sea, advising them to join Cneius Pompey, who was still carrying on the war resolutely in Spain; and then, according to the philosophy of the Stoics, determined not to survive the fortunes of the party to which he was attached, and which, in fact, by his impatience, he largely contributed to ruin. He supped calmly, nothing doubting that the false pride which urged him to suicide was a serene and noble virtue; passed the evening in reading the "Phædo" of Plato, a treatise on the immortality of the soul, and then gave himself a wound of which, though it was not in the first instance mortal, he afterward died, tearing off the bandages with which his friends had endeavored to stanch the bleeding, and expiring from loss of blood. The true reason of this unphilosophical death, which, as such deaths usually do, turned out in the event to be a premature and ruinous dereliction of duty, was simply that Cato was too impatient to struggle to the end, and yielded to

CATOPTROMANCY, a species of divination by the use of a mirror. Plutarch says that before the temple of Apollo at Delphi there was a fountain, and an oracle was given, not for all events, but to a sick person let down a mirror on a thread till its base touched the water. Then, looking in the mirror, the presage of death or recovery appeared. Another method was to place a mirror before a person whose eyes were closed, and the visions which the person saw were taken as omens.

CATRAIL, Dr. F. L. This singular ruin in the county of Scotland. They are a fosse and double round forts or towers, formed in ancient times by the Britons again. They extend from one southward to Peel-20 to 24 feet in width.

**ATS, JACOB**, a statesman and poet of Holborn at Brouwershaven, in Zealand, Nov. 1577, died at his rural retreat, Zorgvliet, Hague, Sept. 12, 1660. He studied at Orleans, and Paris, and on his return to the land published some successful poems. The peace ended also his fortune and at, his possessions being submerged by or devastated by armies. In 1627 he went to England, and in 1636 grand pensioner of Holland, but in 1648 devoted himself to literature. The disagreements between England and Holland during the protection of Cromwell caused his return to England as ambassador in 1652. He is one of the fathers of English literature, and a new edition of his works, in 19 vols., appeared in Amsterdam in 1800, a German translation of part of them been published at Hamburg in 1710. A monument was dedicated to him at Amsterdam in 1829.

**CATSKILL EYE**, a semi-transparent variety of quartz penetrated by fibres of asbestos. It is only of a greenish gray color, though sometimes yellow, red, or brown. When polished it reflects a pearly light resembling the eye of a cat.

**CATSKILL**, the capital of Greene co., N. Y., situated on the W. side of the Hudson river, 11 m. from New York; pop. of the town in 1855, 5,710; of the village, 2,520. There are 5 churches, a court-house, a jail, and 2 government offices. A ferry crosses the river, connecting with the railroad on the E. bank.

**CATSKILL MOUNTAINS**, a group of the Appalachian chain, on the W. side of the Hudson river, lying mostly in Greene co., N. Y. The E. base is 7 or 8 m. distant from the village of Catskill. These mountains range parallel to the river only for about 12 m., spurs from the N. and S. terminations turning respectively to the N. W. and W., and giving to the group a different form from that of the parallel ranges of the Appalachians, as seen in Pennsylvania. It differs from these also in assuming the Alpine character of peaks considerably elevated above the general summits. It resembles them in the precipitous slopes toward the E., and the gentler declivities, which are in the high lands on the W. side. Its geological structure is almost a repetition of that of the main Alleghany ridge throughout Pennsylvania, the same formations succeeding in the same order from the E. base to the summit, and giving to it, even in a more marked degree than is there witnessed, the terraced appearance due to the alternation of groups of strata that are easily worn away, and that which fully resist denuding forces. Along its base the strata of the old red sandstone formation are seen dipping in toward the central part. These are succeeded by the gray slaty strata of hard texture, which make up the precipitous slopes, except those of the highest summits, which are capped by the conglomerate of white quartz pebbles. This is

the floor of the coal formation. Upon the Alleghany mountain it forms the highest knobs, which present their vertical fronts to the E., and slope away to the W. The dip in this direction being there steeper than the declivity of the mountain, the coal beds find a place above the conglomerate; but upon the high peaks of the Catskills this rock lies too horizontally for higher strata to appear, and a descent to lower levels in a W. direction only brings to view again the same formations met with on the E. side. Thus for want of 100 feet perhaps of greater elevation the Catskills miss the lowest coal beds. Even in the midst of the strata of the conglomerate its carboniferous character is seen by the black shales here and there pinched among its massive blocks, and by seams of anthracite of a few inches in thickness contorted into strange forms. These, before their real relations were understood, led to vain hopes and futile explorations to discover workable beds of coal in the hard sandstones of these summits. But it is now well understood that the Catskills can never claim regard for the value of their mineral productions. Their chief interest lies in the variety and beauty of their scenery. In a field of very limited area, easy of access and soon explored, they present a multitude of picturesque objects, which have long made them a favorite resort of artists and of those who find pleasure in the wild haunts of the mountains. The traveller upon the river is struck by their quiet grandeur and more imposing appearance than that of any other scenery along the Hudson; or, if so fortunate as to view them from the high lands, a few miles E. of the river, when the sun is descending behind their summits and gilding them with its parting rays, he may witness most beautiful displays of colors, and purple tints reflected into the atmosphere from the mountain sides, such as before, seen only upon canvas, he regarded as the exaggerations of the painter. From the village of Catskill a stage road of 12 miles leads to the "Mountain House," a conspicuous hotel, perched upon one of the terraces of the mountain at an elevation of 2,500 feet above the river. Here the traveller finds a cool and quiet retreat from the heat and bustle of cities, and a convenient starting point for his explorations of the mountains. Their features of especial interest are the high summits, which afford extensive views of the fine country around, of the Hudson river, visible with all the towns upon its banks from the Highlands to Albany, and of the mountains of Vermont, Massachusetts, and Connecticut, in the distant eastern horizon. The sunrise, as seen from these summits, or even from the windows of the hotel which look toward the east, presents a spectacle of such magnificence that it claims the first regards. The twin lakes nestled beside each other in their mountain bed are soon reached; and their outlet conducts to what are perhaps the most striking features of the Catskills,

portation of which is greatly facilitated by the N. Y. and Erie railroad, which traverses the county and by the Genesee valley canal, which extends from Rochester to Olean. Capital, Ellicottville.

**CATTARO** (Slav. *Kotor*), one of the 4 circles of the Austrian kingdom of Dalmatia, surrounded by the Adriatic, the Herzegovina, and Montenegro; area about 600 sq. m.; pop. 30,900.

—**CATTARO**, the capital of the circle, is charmingly situated at the foot of the Montenegro mountains, and at the S. E. extremity of the gulf of Cattaro; lat. 42° 25' N., long. 18° 46' E. The town was almost entirely destroyed by the earthquakes of 1563 and 1677, and the population has dwindled down to 3,000 or 4,000. The streets are narrow, but the town is strongly fortified, and the port was made a naval depot in Aug. 1854. The best ships of Dalmatia are constructed along the coast of Cattaro, but the harbor of the town, although one of the best in the Adriatic, is little frequented by shipping. Cattaro, however, takes a fair share in the Dalmatian imports and exports, which amounted in 1855, the former to \$3,350,000, and the latter to \$2,500,000. The principal articles of trade are wine, oil, figs, wool, silk, honey, wax, tallow, smoked meat, dried fish, butter, eggs, cheese, and charcoal. Outside the E. gate of the town is the bazaar, which is supplied with provisions by the Montenegrins, who cross the mountain ridge to bring them to market. The trade of Cattaro is carried on by tribes. The Dobrota tribe trade with Trieste, and are frugal and industrious. The Perastro tribe trade with Venice. The Erzagno tribe are noted for their love of finery. The Ricano tribe are excellent traders, but rather given to sharp practice. Beside these, there are several other tribes of traders. The principal buildings are the cathedral, a collegiate church, 17 other Roman Catholic churches, 2 Greek churches, 6 convents, a hospital, a gymnasium, the residences of the governor and the bishop.—In the middle ages Cattaro was a prosperous republic. In 1420 it submitted to the Venetians; in 1797 it was annexed to Austria; in 1805, by the treaty of Presburg, it was incorporated into the French kingdom of Italy, but did not pass into the possession of the French until 1807, having been occupied by the Russians in the interval. Finally, in 1814 it reverted again to Austria. In 1849 Cattaro organized an independent government, but in Jan. 1850, was brought back under the sway of Austria.—The gulf of Cattaro, or *Bocche de Cattaro*, the Rhizonic gulf of antiquity, is renowned for the beauty of its scenery. The capital of Montenegro, Cettigne, is only 5 hours distant from Cattaro. The weekly Austrian steamer makes the voyage from Ragusa to Cattaro in about 6 hours. The popular language is the Herzegovina dialect of the Slavonian, but Italian is the language of the educated classes, and used in the transaction of public affairs. The majority of the population consists of descendants of the ancient Slavonians,

who invaded the country in the 7th century; of Italians, of Bosnian Greeks, and Servian Morlaks, with a small sprinkling of Germans, Jews, Greeks, and gypsies. Roman Catholicism is the established religion; about  $\frac{1}{4}$  of the inhabitants, however, profess the Greek faith. National schools of a superior class have been established at Cattaro, independently of the schools attached to the convents.

**CATTEGAT**, or **KATTEGAT**, a large strait lying between Sweden and Jutland, communicating with the North sea through the Skager Rack on the N., and with the Baltic through the Sound and the Great and Little Belts on the S. Length 150 m.; breadth in the central part about 90 m. It is difficult of navigation, being not only shallow toward the shores and irregular in depth, but obstructed by several sand banks, one of which lies in the middle of the channel. The herring fishery is carried on extensively in its waters. The chief islands are Lasøe, Anholt, and Samsøe. On the Kopper ground in the Cattegat, there is a light-ship with 3 lights.

**CATTERMOLE**, **GEORGE**, an English artist, born in 1800, at Dickleburgh, Norfolk, best known as a delineator in water colors, although of late years he has worked chiefly in oil. Cattermole occupies a field in modern art almost entirely his own. He places on canvas the romance of history. Into architectural designs of an elaborate character he introduces groups which tell the story. His cathedral interiors are remarkable for effects produced by striking contrasts of light and shade. Scenes from the feudal ages and the times of the English civil wars are his favorite themes. These permit him a variety of ornamentation and warm coloring. His most celebrated pictures are: "Luther before the Diet of Spire," "Raleigh witnessing the Death of Essex," and the "Skirmish on the Bridge." He has painted innumerable interiors of church and castle, together with designs illustrative of Scott's novels, Shakespeare's plays, the times of the English cavaliers, &c. Mr. Cattermole, who resides in London, now seldom places his works on exhibition. His pictures bear high prices in England.

**CATTI**, or **CHATTI**, an ancient German people, not very well known to the Romans, who never subdued them, although they made several incursions into their territory and slaughtered women and children. It is scarcely possible to arrive at any thing satisfactory concerning even the country which they inhabited, so irreconcilable are the contradictions. Cæsar only knew that they lived beyond the Ubii, whose seat was about Cologne; and that they were divided, inland, from the Cherusci by a wood which he calls Bacenis. In one place, we are told that they dwelt N. E. of Mount Taunus, still known by the same name, which occupies the abrupt angle of the Rhine between Boppard and Mentz, among the head waters of the Eder and Weser; that their capital was Mattium,

and provisions; so that, while other tribes go out prepared for battle, the Catti march in a condition for a campaign." They did not allow their young men to cut their hair or trim their beards, until they had slain an enemy; and all youths of unusual strength and size were compelled to wear an iron ring, after a certain age, as a mark of dishonor and reproach until they should have gained the right to remove it by slaying a man in battle. They had no individual property of land or houses, no care for tomorrow. Every one was fed, wherever he chanced to be at the moment; equally careless of their own, and lavish of that of others, whether it were property or life, they persisted thus until extreme old age deprived them of such robust and hardy vigor.

**CATTLE**, a class of domestic animals. In its primary sense, horses and asses are included in the term, as well as oxen, cows, sheep, goats, and perhaps swine. In England, beasts of the ox species are more precisely described as black cattle, or neat cattle. In the United States, the term cattle is usually applied to horned animals alone. Like that of many other species of animals now domesti-

United States by the late Roosevelt, N. J. They have wide-spread coarse flesh, but fatten easily. In exist many singular and distinct most remarkable of which is, perbrated sacred or Brahminic bull, dolent, phlegmatic animal, with horns, large pendulous ears, a mous hump and dewlap of skin which never, even under the heat of sun, is known to "melt, than itself into a dew." Its coat is sleeker than even that of the bison while its form approaches nearer bison. Beside this, they have rose, almost hairless-lidded buff and half domesticated, with a crescent-shaped horns, of 18 inch root, and 4 or 5 feet measure round curve; the beautiful, little, hump zebu; that strange animal, the wing ox of Thibet, with a tail like horse; and probably many other imperfectly known and undescribed formerly supposed that domestic descended from the wild European

size, compactly built, invariably of cream-colored white, with jet black hoofs, and the upper half of the black or dull red. They are represented as having formerly had manes; but this characteristic is lost, although their indomitable and desperate ferocity remain un-

Within a few years three herds of were in existence; one in the chase of Ham castle, the property of the earl of Northumberland; one in that of Hamilton, at Hamilton castle, Scotland; and one at Drumlanrig, in Dumfriesshire.

Lord Tankerville's herd were red-deer. The duke of Hamilton had the which are considered characteristic of the Scottish race. Although kept in it within vast enclosed chases, these are perfectly wild, tameless, and savage. They hold no connection with other deer than the red deer will with the stag; they would not brook the approach of man, and have evinced their original wild nature by their ferocity with which the cows concealed themselves in deep brakes of fern or undergrowth, and resisted any approach to their lair. even that, if discovered, they would destroy their offspring, as the bulls are known to do their disabled or superannuated animals. The structural characteristics of these cattle differ in no respect from the domestic ox; their invariable self-evidence of the purity and of their breed, as it is a strong proof that they are not the descendants of tame deer, but have elapsed into a savage state; since this is the case with the South American guanaco, which retain their variegated hues, and are free of domestication and servitude. In the cattle of continental Europe, the Polish oxen are large, strong, and dilligent, the flesh being succulent and red. The cows are shy, not fit for milking; color light gray, seldom black. The oxen docile at work. On the island of Jutland, Holstein, and Schleswig, there is a fine breed with small, crooked horns, supposed to be allied to the Friesian and Dutch breeds; colors various, mouse-colored interspersed with white being most common.

Red cows of this breed are seldom good milkers in moderate quantities. The oxen fatten well when grazed or fed the proper age, being fine in horn and in loin, but not as hardy and strong as the Hungarian breed. Nearer the Alps the cattle are stronger and more active. In the mountains are among the Swiss. The Freyburg breed is very rich in pastures in the vicinity of Gruyères. The cows most prized are those with a wide in the flank, strong in the horn, and strong in bone; they show a prominent root of the tail which would be a blemish by short-horn breeders. The land is rich in pasture, or when stall-fed with lucern; the oxen are good work-

era, but heavy and slow, and fatten well. In the Jura there is a small, active mountain breed, that keep well on little food; they are of a light red color; oxen active and strong for their size, drawing by the horns. They are not profitable for stall-feeding, but good for mountain cottagers, as they climb like goats, feeding on the patches of pasture. The Norman breed give character to all the cattle in the north of France, except near the eastern frontier; they are light red, sometimes spotted with white; horns short, set well out, and turned up with a black tip; legs fine and slender; hips high; thighs thin; good milkers, with rich milk. They are usually fed on thin pastures, along roads and the balks which divide fields. In Normandy the pastures are better, and the cattle larger. The Alderneys or Jerseys, in France, are supposed to be a smaller variety of the Norman, with shorter horns and more deer-like forms. This breed is very docile, having been for generations accustomed to be tethered in fields, along the roads, or in yards. They are found in gentlemen's parks and pleasure-grounds in England. A large number have been brought to the United States, but they are not considered so profitable as some other breeds. The Italian breed is most remarkable for immense length of horn. No pains is expended on this breed except in northern Italy, where the Parmesan cheese is made. The Italian cattle resemble the Swiss.—In England the breeding of cattle has been carried to the greatest perfection. The "Commentaries" of Cæsar state that the British in his time had great numbers of cattle, though of no great bulk or beauty. The island being divided into many petty sovereignties, cattle were the safest kind of property, as they could be driven away from danger. When more peaceful times returned, cattle were neglected for other productions, their size and number diminished, and not until within the last 150 years was any considerable effort made to improve them. The breeds in England are as various as the districts they inhabit, or the fancies of the breeders. A curious classification by the horns has obtained, having been found useful. The long-horns, originally from Lancashire, were much improved by Mr. Bakewell, of Leicestershire, and are now found in the midland counties. The short-horns first appeared in Lincolnshire and the northern counties, but are now found in most parts of the island. The middle-horns, a valuable and beautiful breed, came from the north of Devon, the east of Sussex, Herefordshire, and Gloucestershire. The crumpled horn is found in Alderney on the south coast, and in almost every park in small numbers. The hornless or polled cattle were first derived from Galloway, and now prevail in Suffolk and Norfolk. Which is the original breed of all has been a bone of contention among English breeders. It is held by some that the long-horns are of Irish extraction; that the short-horns were produced by the efforts of breeders; while the polled, though

fixed breeds, as such, were known in England. In the United States there is now a class of native cattle, arising from a mixture of various breeds imported by the early settlers, who, for the want of barns, and from habits established in a milder climate, allowed their cattle to suffer severely; many perished, the survivors degenerating in size and quality. As agriculture advanced and settlers became more prosperous, the cattle were improved; and there are to be found in different districts native cattle varying with the richness of soil, salubrity of climate, and care of breeders. The English breeds, gaining celebrity, attracted the attention of enterprising breeders here, who commenced importing the Durhams, Devons, Ayrshires, Herefords, and Alderneys, with a few Galloways and some long-horns, and occasionally a few Scotch cattle. These cattle, imported at great cost, and not inured to our climate and rough treatment, prospered only in the best situations, and for a long period attracted little attention from ordinary farmers. At present there are

farmers prove better than the short-horns. About 1835 some A were imported, and this breed has since in the United States a high character for yoke, and shambles. They do not seem to find much objection to the cold of Alderneys, of which there are many tions for that breed, and since by Mr. R. L. Colt, who seems admirably adapted to the climate. Though their milk is very small. They are poor for but as workers; some breeders, however, believe them to be very good for butter and cheese. The long-horns are sparingly imported, and do not find much favor. The Sussex are better liked, though few have been introduced, while their supposed superiority to the Durhams is not generally admitted. The most of the older breed, and without doubt they have since improved.

have many complaints, yet generally exempt from great mortality. Occasionally "milk sickness" appears in some of the Alleghanies, when the animal dies, giving the peculiar disease, partake of her milk or flesh. It is to originate from the *rhus toxicodendron* ivy. The remedy is feeding large of Indian corn. The horn distemper sometimes prevail extensively, and as, where the cattle are closely confined fed, they become ulcerated and other-ised. No class of animals are so malades as neat cattle when well. Good pasturage, good hay, grain, water, and airy stables, with suffice, are necessary to maintain good cattle or to improve their condition of food is essential, and the feeding in winter is particularly necessary, place the succulent grass of summer. ce of "soiling" in summer is strongly in England, and has found favor with have fairly tried it in the United the cattle are kept in cool, clean stables, rye, oats, corn sown broadcast, lucern, rghum, &c., are cut and carried to ese green substances should be allowed heat slightly before being used; the sing turned out for 3 or 4 hours in a old without grass. A lump of rock l be put in each manger. It is recom- at on large farms stables for summer placed in the centre of a 40 acre field, it convenient to get food to them, and nanures near where they are required. ord the means of keeping up the fer- farm, and generally a cattle district, her every year, while a grain district the introduction of foreign manures at , grows poorer.—The weekly average on of cattle in the city of New York was: beeves 3,565, calves 922, cows l for the year, beeves 185,574, calves ws 12,110. The annual consumption was estimated, at the period of the sh census of 1851: bullocks 240,000 ves, 28,000 hd., sheep 1,700,000 hd., 10 hd. The consumption of Paris in about 137,000,000 lbs. of all kinds of wing an increase of 6,000,000 lbs. xceeding year.

**KATYWAR**, or **KATTYWAR**, a province comprising the whole of the Indian peninsula bounded on the N. and N. W. by the the gulf of Cutch; on the S. and S. Arabian sea; and on the E. by the district Ahmedabad and the gulf of Cam-reen lat.  $20^{\circ} 42'$  and  $23^{\circ} 10' N.$ , long.  $72^{\circ} 14' E.$ ; area 19,850 sq. m.; pop.

The principal towns are Amreli, Chondla, Buggusra, and Cheetal. The product is cotton. The grains chiefly are wheat, maize, and millet. The is grown extensively, but is only made e molasses or *goor*. The Cattywar

horse, once celebrated, has of late years deteriorated. A breed of kine, called *desam*, and buffaloes are much valued, but not the camel, of which there are only few, and those very small. The soil is sandy and not fertile, but numerous streams and wells afford ample means of irrigation, all the rivers taking their rise in the most central part of the province. Toward the S. some of the hills are over 1,000 feet high. Deep ravines and caverns are very numerous, and afford safe retreats against attack. A locality of wooded hills called the Gir is haunted by wild animals of the most ferocious kind, and noted for its deadly climate. The ravages of migratory rats produced such a terrible famine in 1814, that this year has since been called the rat year. The province is divided into 10 districts, which are again subdivided into the separate possessions of 216 Hindoo chiefs, some of whom are tributary to Great Britain, others to the Guicowar. The Cattywar tribute figured in the revenue of the presidency of Bombay to the extent of £56,105 in 1856. The total revenue of the Hindoo chiefs is estimated at about £450,000. The military force of the chiefs consists of 12,000 men, 4,000 horse and 8,000 foot.

CATULLUS, CAIUS VALERIUS, a Roman poet, born in Verona, 87 B. C.; the time of his death is variously estimated between 57 and 40 B. C. He belonged to an ancient and noble family; his father was connected with Julius Cæsar by the bond of hospitality, being a *hospes*, a tie very sacred among the Romans. The son came to Rome by the influence of Manlius, and became acquainted with Nepos, Cicero, and other great men of the age; possessing a moderate fortune, he did not enter upon public life, but dwelt in retirement at Rome and at his villa near Tibur. He is the earliest Latin lyric poet of any importance. The first attempts of the Romans in lyric poetry may be traced to table, triumphal, and the Salian songs; the Roman lyric may be considered an imitation of the Greek, although possessing peculiar merits of its own. When the Roman character became changed by Christianity, lyric poets became very numerous; this change forms an important epoch in the history of our religion, as some of the most beautiful songs of the Catholic church may be traced, both in their text and music, to this time. We have 116 poems of Catullus, mostly short ones, and without arrangement by subjects; a few belong strictly to lyric poetry, some are elegiac, but most are epigrammatic. From his imitation of the Greeks, Catullus has been called *doctus*, but, next to Lucretius, he possesses the most originality; there is in his style a certain air of antiquity which the Romans greatly admired. The text of Catullus seems to have been early corrupted; all MSS. are derived from one source, and that an imperfect one. There are several poems of unknown authorship, which are ascribed to Catullus; the elder Pliny mentions *De Incantamentis*. *Ciris* and *Pervigilium Veneris* have been attributed to him, but the latter is now generally believed to

in wine, and more actively in slate, of which there are extensive quarries in the lateral valleys. Pop. about 1,500.

CAUCA, a state of New Granada, bounded N. by the Caribbean sea, W. by the Pacific, S. by Ecuador, and E. by the provinces Magdalena and Cundinamarca, divided into the 4 districts of Popayan, Choco, Buenaventura, and Pasto. Area 68,300 sq. m. Pop. in 1858, 49,000 Caucasian whites, 25,000 civilized Indians, 88,000 negroes, 14,600 quadroons, 88,049 mestizos, 114,800 mulattoes, 2,300 zambas; total, 276,249. The principal town is Popayan, near the 2 famous volcanoes of Purace and Sotara. The principal mountains are the Paramo de Guanas, the Quindiu, Pasto, Sindagua, all branches of the Cordilleras de los Andes. The principal productions of the state are gold and platina. The soil is very fertile, and cattle and sheep abound. • Cocoa, cotton, tobacco, coffee, and various kinds of grain and rice, are also produced. The sea of Papas in this state is the source of the Magdalena river. Among the rivers is the Pusambio, which springs from the volcano Purace, the hot acid waters of which are poisonous and produces a dangerous disease of the eyes; the Atrato, which is united with the San Juan

from Transcaucasia, and form the boundary between Europe and Asia. The line of the country would represent a series of round-topped mountains (except those peaks which belong to other chains), their bases forming fertile valleys, descending to the plains which stretch N. to the Cossacks, and S. to the whole region known as Caucasus, within lines extending from Koor on the Caspian, in lat. 39', and 41st parallels in a N. E. direction to the mouth of the Rion, or Phasis, on lat. 42° N., and from the mouth of the Kooban, on the Black sea, in lat. 44°, to the extreme points being, on the N. E., in long. 37°, and on the S. E., in long. 41°. The territory is roughly estimated at 56,000 square miles. N. of the Caucasian mountains formerly known as the Russian government of Caucasus, also a part of the Russian empire, but it now forms the Russian government of Astrakhan. The vast tract of country between the mountains forms the present Transcaucasia. The Caucasus

these subsidiary chains are Elvend both on the N. The principal Mount Elbrooz, the highest point variously estimated at 16,500 and univari or Kasbek, 14,500 feet; on the confines of Daghestan, Djouar-Vahé, estimated at 8,000; 7,000 feet. The passage of these effected through defiles, some of historic celebrity. Such are the w called the Dariel pass, the Al-urmatic pass in Daghestan, the ear Teheran, and the Iberian, now aourapé pass. Only one road is or carriages, namely, the pass : to Tiflis, by the valley of the mountains of the Caucasus are round-topped. The following table presents an

approximate estimate of the average value of the principal products annually exported from the Caucasus:

Wheat.....	\$10,000,000
Barley.....	2,500,000
Buckwheat.....	800,000
Maize.....	200,000
Cattle.....	14,000,000
Saffron.....	75,000
Madder.....	65,000
Wine.....	2,500,000
Brandy.....	300,000
Silk.....	80,000
Cotton.....	150,000
Total.....	\$32,970,000

Few minerals have been discovered; gold appears to be totally wanting; iron, copper, salt-petre, and lead are found, the latter in considerable quantity.—The Caucasians are generally a bold and restless people, hunters and guerrillas from choice, shepherds and agriculturists only from necessity. Although hospitable, they are jealous and revengeful. Like all mountaineers, they are endowed with an indomitable love of their country. They live in villages built of stone, around a citadel which they garrison in time of danger. Until recently their youth of both sexes were raised for sale in the slave markets of Constantinople; but that traffic has been suppressed. Their political organization was formerly a loose sort of republicanism, under the nominal presidency of a hereditary prince. Recent events have materially modified that form. Literature they have none. Their religion is an offshoot of Mohammedanism, corrupted from many sources. Of late, Shamyl, the Circassian chieftain, has instituted a new creed, of which the principal tenet is obedience to the divine communications received through himself. Probably the total population of the Caucasian region is not short of 2,500,000.—Ancient history makes frequent mention of this region. Here Prometheus was chained. Deucalion, Pyrrha, and the Argonauts, Scæstris and the Egyptians, the Scythians, Mithridates, Pompey, and Trajan, are associated with its history. The Arabs, Mongols, Tartars, and Turkomans successively ravaged the countries to its base. Russia and Persia then struggled for its possession, until, in 1813, the Russians became nominally possessed of it by successive treaties. For the past 20 years a constant war has been carried on between the Caucasian mountaineers and the Russians. Since 1800, when Georgia was annexed to the empire of the czar, the Russians have been untiring in their efforts to reduce the mountain tribes, which form a barrier to their advance eastward. A desultory warfare of several years ended by the mountaineers being reduced to a condition nearly approaching to subjection. But in 1823 a new movement sprung up in the mountains. Mohammed, the Mollah, commenced against the Russians a campaign in Daghestan. A chieftain named Kasi-Mollah was soon recognized as the head of the movement, having for his aid Shamyl, then a young man, but who has since

become famous as the Circassians' chief. This chief, Kasi, kept up a brilliant resistance to the Russian power till 1831, when he was shut up in Himry. The Russians stormed the place, and gained possession of it only when the last of its defenders had perished; the chief himself was slain. Iiamsad Bey next took the field, and devoted his first care to coercing into neutrality the disaffected tribes, but his career was cut short by assassination. The Mollah Mohammed being now dead, Shamyl was elected his successor. From that day to this the war has been carried on with varying success, but has never flagged. The campaign of 1837 terminated by the capitulation of Shamyl, who was besieged in Tilitla. During 1838 the Caucasians were employed in preparing themselves for future resistance, several of the disaffected tribes joining them. The passes of the mountains were fortified, and the strong position of Akulgo was put in readiness to stand a siege. In the succeeding year the Russians, under Gen. Grabbe, entered the territory, defeated the Caucasians, and drove them back upon Akulgo, which was finally taken after a blockade of 72 days, and 3 days' hand-to-hand fighting. The Caucasians once more nominally succumbed to the Russian power. In the next year, March, 1840, they again revolted. Having found European tactics ineffective in the previous campaign, they fell back on their old system of guerrilla warfare. Lesghistan and the Tchetchentsi were formed into a military organization, which enabled them to throw their force on any point. Gen. Grabbe again attempted to penetrate into the mountains, but was compelled to retreat with much suffering to his army. The next attempt to conquer this brave people was made in 1845 by Prince Woronzoff, who bore the appointment of governor-general of the Russian Caucasian provinces. Woronzoff penetrated to Dargo, which he found in flames. The campaign being over, Woronzoff returned home. By his recommendation a new plan of action was introduced against the mountaineers. Hitherto the tactics had been to bring them to pitched battle, with the hope of breaking their strength at a single blow. Now the plan was to send detached columns against isolated spots, and wherever a footing was obtained, to erect a fort on it. Notwithstanding this, the Caucasians have been able to carry on offensive operations. In 1846 they swept the line of Russian forts, and returned to their mountains laden with plunder. In 1848 and 1850 they made similar expeditions, and in 1853 they took from the Russians several guns, and drove them back from 8 leagues of territory. During the Crimean war the Circassians refrained from taking a conspicuous part. They embraced the opportunity to consolidate their own resources for the renewed struggle with Russia, which they foresaw awaited them when the Crimean war should be over. The destruction by the allies of the Russian forts on the eastern coast of the Black sea was a fortunate circumstance for

the Caucasians, and of whose use. As soon as the war was over again turned their arms; the struggle continues to the whole territory allied to into four provinces, each entered by a lieutenant-general. Each is subdivided into 5 districts, called over each of which presides a Naib, required to maintain 300 horsemen. Bariatinsky left Russia in Oct. 1 the functions of governor in the

CAUCASUS, INDIAN. See E

CAUCHY, AUGUSTIN LOUIS, a mathematician, born in Paris, Aug. 21, May 23, 1857. His father, the poet and keeper of the archives of the peers (born 1755, died 1847), gave him a liberal education, and he early showed talent both for poetry and mathematics. He was admitted in 1805 to the *école polytechnique*, distinguished himself by the solutions of problems, and maintained the reputation of the school, and afterward in the *École des sciences*. From the year 1818 down to 1840 he poured forth almost incessantly his mathematical research. Scarce a branch of mathematics, pure or applied, does not owe some of its progress to his labors. His fame will rest chiefly on his *Leçons sur le calcul différentiel et intégral*, and his *Leçons sur les fonctions de la théorie des nombres*. He was admitted to the academy in 1816, the same time appointed professor at the polytechnic school. He delivered "Lectures on Analysis;" in "Differential Calculus;" and in "Lectures on the Applications of the Calculus to Geometry." The *Œuvres complètes* of Cauchy contain numerous and valuable papers in his pen. He is highly honored in his country both for his genius and his private character; but his attachment to Bourbon prevented him from taking the necessary advantage, by which alone he could have obtained the offices which he held in France. He offered him on subsequent occasions, however, he was appointed professor of mathematical astronomy which he taught at the Paris university. He took the requisite oath and relinquished this post in June, 1830, for his religious writings to which he gave his legitimacy in politics, in France in religion. One of his works of the kind is *Essai sur l'Espagne*, which was published in 1808.

CAUCUS, a word employed in the United States to denote the of the political machinery which, though unknown to the institutions and the manner of a marked feature in the system. The origin of the word is probably in the

diary, dated Boston, Feb. 1768 :  
 I learned that the caucus club meets  
 1 times in the garret of Tom Dawes,  
 1st of the Boston regiment. He has  
 a house, and he has a movable partition in  
 it which he takes down, and the whole  
 is in one room. There they smoke  
 and you cannot see from one end of the  
 room to the other. There they drink flip, I  
 and there they choose a moderator  
 to ask questions to the vote regularly, and  
 12 overseers, collectors, wardens, fire-  
 representatives are regularly chosen  
 are chosen by the town. They send  
 messengers to wait on the merchants' club, and  
 to go and join in the choice of men and  
 women. Capt. Cunningham says they have  
 elected him to go to those caucuses," &c.  
 in the following passage of his "His-  
 tory of the American Revolution," under date  
 of 1768, at which time he was minister of Rox-

Boston, and very intimate with the  
 leaders of the day—traces back this  
 to a much earlier date: "More than 50  
 of Mr. Samuel Adams's father and 20  
 or two from the north end of the  
 town, all the ship business is carried on,  
 and they make a caucus, and lay their plans  
 by inducing certain persons into places of  
 power. When they had settled it, they  
 and used each their particular influence  
 in their own circle. He and his friends would  
 surround themselves with ballots, including the  
 names of the parties fixed upon, which they dis-  
 tribute on the days of election. By acting in  
 concert together with a careful and extensive  
 distribution of ballots, they generally carried  
 their own plans to their own mind. In like man-  
 ner as that Mr. S. Adams first became a  
 representative for Boston." It has been plausi-  
 bly conjectured that caucus is a corruption of

Very likely the caucus club which  
 Tom Dawes's garret was originally a  
 sailors' club, called, from the leading trade  
 of the sailors' club, which name, with a  
 change, it still retained after it had passed  
 into the hands of politicians. The change of  
 name consequent on the revolution led,  
 in the northern states especially, to a great in-  
 crease in the number of elective offices, while  
 the ruling idea of the impropriety of self-  
 nomination and of a personal canvass for votes  
 rendered nominating and canvassing machin-  
 ery necessary. Meetings held for this purpose  
 took the name of caucuses. These caucuses  
 were no longer private clubs.—Soon after the  
 adoption of the federal constitution, the people  
 of the United States became divided into two  
 marked parties, the federalists and the  
 republicans. Even the local elections of the  
 places speedily came to turn for the  
 result on this great national party division.  
 In each election district its own  
 party nominated candidates. Public notice  
 of time and place was given, and every  
 member of the party was at liberty to attend; but

of course the attendance was chiefly composed  
 of zealous politicians. A moderator and clerk  
 being chosen, a nomination list was opened.  
 Each person present nominated whom he pleased.  
 Several copies of the list were made and dis-  
 tributed through the meeting, each person  
 placing a mark against the candidate whom he  
 proposed, and the candidate having the highest  
 number of marks was declared the nominee.  
 This method, however, was evidently inapplica-  
 ble where the constituency was large or the dis-  
 trict extensive, as was the case when state sena-  
 tors or representatives in congress were to be  
 chosen. Hence the substitution of a representa-  
 tive caucus, delegates being appointed at meet-  
 ings like that above described, held in case of  
 cities and large towns in the wards, and in coun-  
 try districts in the townships. These elective  
 caucuses commonly took to themselves the name  
 of nominating conventions, and their introduc-  
 tion marks a third era in the development of  
 the caucus system. A considerable period,  
 however, elapsed before this convention system  
 was applied to state or presidential nominations.  
 The members of the state legislatures in the one  
 case and of congress in the other—those of each  
 party holding their own separate caucus—took  
 upon themselves to make these nominations.  
 At first these legislative and congressional cau-  
 cuses were held privately, the result being grad-  
 ually diffused among the local leaders of the  
 party by private correspondence. Afterward,  
 however, they came to be formally and avow-  
 edly held. Committees were appointed to look  
 after the elections, and beside a state commit-  
 tee the legislative caucuses assumed the power  
 of nominating the chairmen of the local county  
 and district conventions. At length it began  
 to be objected that in these legislative caucuses  
 only those districts in which the party was in  
 the majority were represented, and this and  
 other causes led, between 1820 and 1830, to the  
 substitution in New York and Pennsylvania of  
 state conventions in their place—a custom since  
 universally imitated. Congressional caucuses  
 about the same time fell into disfavor. That  
 held in 1823 to nominate a successor to Mon-  
 roe was but slenderly attended; and its nomi-  
 nation was extensively disregarded, so that Mr.  
 Crawford, its nominee, was behind both Jack-  
 son and Adams in the popular vote. At the  
 presidential election of 1828, Adams became  
 the candidate of one party and Jackson of the  
 other, without any formal nomination. Indeed,  
 it may be observed of the congressional caucuses,  
 that so far as the presidency was concerned  
 they all, except the last of which the nomination  
 failed, did but select the candidate already des-  
 ignated by popular expectation. The con-  
 gressional caucus system being exploded, the  
 Jackson or democratic party held in 1833 a  
 national nominating convention, each state  
 being entitled to the same number of votes as  
 in the presidential election, and similar conven-  
 tions of that party have been held to nominate  
 candidates for each succeeding presidential

citement, fidelity to regular nominations being zealously inculcated by caucus politicians, both as indispensable to success and as the greatest of political virtues. Membership of these conventions, when made an object of contest, is generally attained by superior adroitness and audacity. Gross frauds, and in some cases open violence, are resorted to, possession of the majority in the convention ordinarily carrying with it, as between the different cliques contending for its control, the leadership of the party. The caucus system is thus often converted into a contrivance for the distribution of offices among men more distinguished for intrigue than for talent, who, by combination and mutual support, and by serving each other's turns, are often raised to offices, and sometimes very high ones, for which, apart from a caucus nomination, they would hardly have been thought of as candidates.

CAUDEBEC, a French town on the Seine, department of Seine-Inférieure, 26 m. E. of Havre. Pop. 2,567. The principal edifice is the parish church, a celebrated Gothic building in the florid style of the 15th century. It was taken by the English in 1419, and by the Protestants in 1592 it was burned by Alexander

marquis of, and duke of Vic general and diplomatist, born department. Aisne, Dec. 9, 1787. He Paris, Feb. 19, 1827. He at an early age; being was deprived of his property, and cast into prison; and by the intervention of his friends reinstated in the army. He went to the Turkish embassy at Constantinople, distinguished himself in the campaign of Moreau, and was sent by the French government to the Russian emperor Alexander I. on his return to France. He was on staff. While engaged in military operations on the Rhine, he was arrested and shown that Caulaincourt had accompanied Napoleon in 1806, and 1807; in 1812 minister to Russia. After the battle of Waterloo he took him as his trustee. He took a prominent part in the 2nd chamber of the French Assembly and lived in France.

a. It has a compact rounded head of deli-  
 or, standing on a stalk 18 to 26 inches  
 and surrounded by long leaves. The  
 are not closely packed as in the cabbage.  
 re tender than the cabbage, and in  
 ating should have a ball of earth lifted  
 roots to secure a continuous growth.  
 vicinity of New York 2 crops are raised  
 kitchen garden in one season. If the  
 cauliflower does not come to perfection  
 end of June, it will usually fail to head,  
 excessive heat at that time. To ob-  
 for this crop seeds should be sown in  
 in good soil, and in about 4 weeks  
 into a cold frame, set 2 or 3 inches  
 carefully protected by glass during  
 or, being opened to the air only during  
 days. In February they should be set  
 other frame, 8 to 12 inches apart, to  
 a spindling growth. They should be  
 ted as early in the spring as possible,  
 nce of 3 feet from each other, and well  
 and frequently hoed during the dry  
 At the time of heading, the larger  
 y be broken over the head to protect  
 the sun, and the waterings should be  
 ment. For a late crop the seeds are sown  
 n open bed in May, and the transplanting is  
 uly. Those plants which do not head be-  
 frost may be removed to a warm shed or  
 r, covered with coarse litter, and allowed  
 ead during early winter.

AURA, a river of Venezuela, formed by the  
 tion of the Yurani, Erevato, Mareguare, and  
 ral of their tributaries. It unites with the  
 oco after a N. course of about 150 m.

AURSINES, or CAORCINI, also CAORSINI,  
 an usurers in the middle ages, who were  
 driven out of the countries in which they  
 led, on account of their merciless exactions.  
 r derived their name from Cahors, which  
 one of the head-quarters of the same class  
 arsons in southern France.

AUS, SALOMON DE, a French engineer, archi-  
 and author, died about 1635. He was  
 probably at Dieppe, devoted himself with  
 r to mathematics, making Archimedes,  
 uvius, and Euclid his favorite reading;  
 t in 1612 to London, where he was at-  
 ted to the prince of Wales, afterward  
 rles I.; lived from 1614 to 1620 at Heidel-  
 , at the court of the elector palatine Fred-  
 V.; and returned to France in 1624,  
 re he received the title of royal engineer  
 architect. He wrote several ingenious  
 ks, in one of which, entitled *Les raisons*  
*forces mouvantes*, he speaks of the expan-  
 and condensation of steam in a way natu-  
 r to suggest the alternate action of the pis-  
 and the principle of the steam engine; it  
 therefore been claimed that the marquis of  
 rcester borrowed from him the discovery of  
 properties of steam as a motive power.

AUSE. Few words are more conspicuous  
 he discussions of philosophy than this, and  
 if any principles lie deeper in its foun-

dation than that which it has been used to  
 denote. It would require a thorough review  
 of the history of philosophy and of the various  
 systems that have been taught, to give a satis-  
 factory exposition of all the senses in which  
 the word "cause" has been used, and of all  
 the theories of causation; this is of course im-  
 possible in this place. The discussions of  
 cause appear to have assumed a scientific form  
 first with Aristotle ("Posterior Analytics,"  
 ii., chap. xi.). Aristotle reckons 4 kinds of  
 causes—efficient, final, material, and formal.  
 The first or efficient, being the force, en-  
 ergy, or person by which any thing has been  
 brought into being, is of necessity prior to the  
 effect or thing produced; the second or final  
 cause is the object for which a thing is pro-  
 duced, and does not really exist until after the  
 effect, and is in some sense the effect of the  
 effect. Material causes, as Aristotle says ("Me-  
 taphysics," vii. 4), exist only in physical substan-  
 ces; as, for example, marble is the material  
 cause of a statue, or in general that of which  
 anything is made is its material cause, and the  
 tools, machinery, &c., by which its specific form  
 was given to it, are its formal cause. In a short  
 time, however, these definitions came to have a  
 more metaphysical meaning, and even Aristotle  
 himself, in the "Analytics" as cited, uses the  
 words material and formal as denoting kinds  
 of cause, in a sense much the same as they came  
 to have afterward with the schoolmen of the  
 middle ages. In this use the material cause is  
 the *essentia* of the conception, and the formal  
 cause is the *differentia*. Hence with them the  
 definition of a thing is by means of its material  
 and formal causes, that is, the *essentia* and *differe-*  
*entia* of its conception. In this view, to illus-  
 trate the uses of the word cause, the effi-  
 cient cause of man would be his Creator; the  
 material cause, in the physical sense, the carbon,  
 oxygen, lime, &c., of which his body is com-  
 posed—in the metaphysical sense, the properties  
 common to animal life; the formal cause, in the  
 physical sense, would be any instrument or  
 means with which creation had been effected, if  
 such there were—in the metaphysical sense, it  
 would be the distinguishing characteristics of  
 human nature; and the final cause, in the lan-  
 guage of a well known theological formulary,  
 would be "to glorify God and enjoy Him forever."  
 In reference to the material and formal causes,  
 it is evident that the different senses of the  
 word arose from a change in the real object  
 contemplated. In the one case it was the out-  
 ward visible object, the ontological reality; in  
 the other, it was the conception of that reality;  
 and hence the terms in modern use, "the mat-  
 ter of a conception," that is, those essential prop-  
 erties of the object by means of which it is cog-  
 nized as existing, and which Dr. Wilson in his  
 "Logic," p. 209, proposes to call material proper-  
 ties, as being those on which demonstration is  
 based. So, also, the formal cause of a conception  
 can be only those properties by which its ob-  
 ject, or objects, if it be the conception of a spe-

that case the motive of the agent and his gratification have come to be called the final cause, though this is more properly, and generally in fact in modern times, called the moving cause. Swedenborg, however, and after him the Swedenborgians also, generally and perhaps exclusively use the words final cause or end in the metaphysical or subjective sense. That which was called efficient cause by Aristotle has since been distinguished into two classes. And even his definition seems to be somewhat vague, "that which first moves something," that out of or from which the force emanates that caused the motion; this definition is found to apply equally to two distinct forces, called in later times the efficient and the occasional cause. For example, in the explosion of gunpowder, the spark which ignites it would be called the cause of the explosion; but yet the spark is a cause in a very different sense from the expansive force of the gases, especially the nitrogen, which are consolidated in the powder. The gases would not explode without the spark, nor the spark cause an explosion without the gases, or in case it had fallen upon sand or onion seed; and yet both are included in Aristotle's definition. The importance of this distinction

change itself from rest to motion, from motion to rest; 1 s du objects have been very, by only secondary causes. Among causes arose among the school they are called transient, permanent causes; these 8 w the 8 great theos of the creation s c world. A good as follows: The cause of the light which is in streets; the gas or oil that is the cause; and the ignition of the gas itself is the immanent cause. will be seen that transient causes may be efficient causes, but the cause must be not only but in the physical sense also. If, now, God is of the universe, we have nature itself is only God. This is the the of L ers, and in f pantheism: transient

the creation of his own mind, and long as that mental activity in which their origin continues, and no longer in this view the objects of nature would be denied to have any substantial reality, but merely phenomenal. This seems to be the view of Schelling and of Cousin, and has been expressly announced by Coleridge; and these philosophers of course giving to the some modifications and peculiarities of their own. Second causes, also, are sometimes distinguished as immediate or remote; immediate being that antecedent of any effect which lasts last in the order of time before it, the remote cause was any one of the secondary causes (and sometimes even the efficient cause is so called) on which the events are fixed. In the light of the distinction between first and second causes, every act of thought, except the absolute cause and only an absolute effect, is conceived as both cause and effect; and so cause and effect, with the exception just made, are but alternate conceptions of the same thing. Any object, considered in reference to what preceded it, is an effect, and in reference to what follows it in the order of causation, is a cause. Then again, causes are of 3 kinds: negative, substantial, and modal. A negative cause is ontological unreality, which, however, may be denoted by either a positive or a negative term. Thus we say that cold congeals, darkness makes the plants that grow to be white or without color; here cold and darkness are spoken of as causes, but in a scientific point of view they are regarded as mere absences of positive reality—heat and light being considered as real, the absence of heat, and darkness the absence of light. And in general, the absence of either an occasional or an efficient cause is spoken of as a cause of any event or result which would have been prevented if the cause had been present and active. The distinction between substantial and modal causes is in reference to the fact that a cause to be real must be substantial, while its efficiency as a cause often depends upon its being in a certain mode. Thus, for illustration, when a man steps on a worm and crushes it to death, we say the step causes the worm's death. But the step is not a substance, it is only a mode; the foot caused the worm's death, but only by being in a certain mode of stepping. Hence the foot is the substantial cause, the step the modal. This distinction is based upon an idea in relation to causation of which we shall speak more fully hereafter, and which if it is received cannot fail to exert a great and very marked influence upon the whole of the teachings of metaphysical science.—Theories of causation are intimately connected with and dependent upon the theories of the origin of the idea of cause. Of these there are 4, which seem to be all that are possible. The first is the theory of innate ideas introduced by Plato, modified by Carneades, and

adopted by the realists generally in the mediæval schools. The second is the theory first suggested by Leibnitz, and adopted by the modern idealists generally, from Kant to Cousin and Sir William Hamilton, who seem to have given to it a more minute exposition and a more preëminent place than it had occupied even in the writings of Leibnitz. According to this theory, certain ideas, and among them that of cause, which represent to the mind objects not cognizable by the senses, are the product of the mind itself acting spontaneously and according to the laws of its own constitution. The third theory is that of the sensationalist, who holds that all ideas are produced from the action of objects upon the senses. It has been objected to this theory that it leaves no room for the distinction between causation and mere antecedence; and Hume so taught, denying that our idea of cause implied anything more than a mere uniform or general antecedence of that which we call the cause of any event. This is regarded as a successful *reductio ad absurdum*, for it is certain that all men make a distinction between cause and mere antecedent. Nobody is content to use the words as mere synonymes. For example, a man eats his breakfast and is hungry at noon, he eats a dinner and is hungry at evening, takes his supper and rises hungry again in the morning; and yet no one ever supposes that the food is the cause of the hunger that follows the taking it, notwithstanding the uniformity with which the one phenomenon follows the other. To the view of Leibnitz and the idealists it is objected, that if the principle of causation, namely, that every effect must have a cause, is evolved from the idea of cause, and the idea of cause is the mere spontaneous product of the mind, then neither the idea nor the principle of causation can rise to a certainty above the mere subjective necessity of our thinking thus and so rather than otherwise, which is in fact Sir William Hamilton's view; that is, the principle itself rests rather upon the nature of the admitting mind than upon that of the admitted truth. In view of these objections, and on other grounds, Dr. Wilson has proposed a new theory of the whole subject. In the first place, he denies both the Platonic and Carneadean theories of innate ideas, and the Leibnitzian theory of their spontaneous production, and holds, in addition to Locke's theory of sensationalism, that we have a faculty of insight or intuition by which we cognize directly and immediately objects, properties, and relations invisible to sense-perception. In the second place, he holds that the word cause, as used in this connection, is an abstract term. It may be a concrete term indeed, as when we speak of the cause of any particular thing; but in that case it denotes only an alternate conception of some reality which we have cognized by other properties, and for which we have another name. But taking the word cause to be an abstract term in its ordinary use without the article, he says that it must denote either a property,

effect, and a certain quantity to produce the effect. Thus, heat is a cause homogeneous to fluidity, and 212° Fahrenheit sufficient in quantity to produce the boiling of water; whereas a much lower degree would be inadequate, and electricity (except as producing heat) would not be a cause homogeneous to the effect. The laws for the investigation of causes are reserved for consideration under the head of INDUCTION.—The question has been raised whether our ideas of causation imply the actual creation of any thing, or only a change in the form of its existence. At first, the idea of cause only includes the latter; for that is all that there is in the external phenomena from which we generalize our idea. And here again we encounter another peculiarity of the theories of causation, namely, the occasional cause of the idea of cause. It is commonly held that the idea of cause arises from seeing the changes that take place in outward nature. Maine de Biran held, on the contrary, that the idea doubtless first arose from observing in the phenomena of consciousness the fact of volition, in which we are conscious of the causal act of producing not only the volition or *visus* that immediately precedes the physical act, but also of producing

ternate conceptions for cannot examine Hamilton's subject in this place, but would gest the inquiry whether that philosopher has not committed take, and supposed that it is the for the object of the conception conditioned, and for the conception unconditioned? No conception tioned. If positive, it is limited in tity, and conditioned by and so the *essentia* and *differentia* of material cause. But can we say that the conception of the I is conditioned, that it is conditioned or we can say of Him? which last is Sir dilemma. The general doctrine is that we have ideas or conceptions of the absolute; that while they are not, and that never can the adequate idea of Him, ask *Why* of Him. On the contrary, we recognize having the ground of I that the supposition of I is absurdity, and in Him we

r, died July 29, 1835. He published editions of some Arabian works which were "Lokman's Fables," the first chapters of the "Koran;" translations of an historical or scientific character, and interesting memoirs in honor of the academy of inscriptions. PIERRE, son of the preceding, born 1795, travelled in the East to perfect knowledge of the Arabic. On his return in 1822, he was appointed professor of the Arabic language, first in the school for oriental languages, then in the University of France. Beside an Arabic grammar, a revised edition of "Ellious Boethor's Arabic Dictionary," he has published an important historical work, *Essai sur les Arabes avant l'Islamisme, depuis Mahomet et jusqu'à la réduction des tribus sous la loi musulmane*, Paris, 1847, and several translations from Persian and Turkish.

**C** (Gr. *καίω*, to burn), a class of substances used for burning out diseased spots on the skin, and for creating artificial sores by which the system may be partially purified of its impurities. In cases of intertrigo these are found very beneficial. The most common caustic employed is nitrate of silver, lunar caustic, being mild and effective; other varieties are arsenic, blue vitriol, and preparations of mercury.—**CAUSTIC**, a bright light, formed by the intersection or reflected rays. If of refracted light, called a diacaustic, if of reflected, a catacaustic.

The most familiar instance is seen in the steam which rises from a wet cloth inside a polished napkin ring. **C**ETS, a French watering place in the department of Hautes Pyrénées, situated in a basin 2,900 feet above the sea, and surrounded by rugged mountains. It has hot springs whose temperature varies from 100° to 140° F.

**C**Y (Gr. *καυτηριον*, burning), the application of caustic to the flesh, or with a hot iron. The former was used by the ancients, and the latter is the actual cautery.

**C**ITY of Naples, in the province of Campania, situated in the agreeable bay of Baia, 26 m. S. E. of Naples; pop. 120,000. It is the seat of a bishop, suffragan, and has a cathedral, several convents, and a convent for gentlewomen. The soil is unproductive, but the town is supported by commerce and by manufactories in silk, cotton, and woollen. About one mile from the city is the celebrated Benedictine monastery of *Trinità della Cava*, whose library, now transferred to Naples, were the most valuable in the kingdom.

**CAVAIGNAC**. I. JEAN BAPTISTE, a member of the first national convention, born in 1762, died in 1829 at Brussels. Having been a member of the Haute Garonne academy, and a great popularity in that department, he

was elected to the convention, where he voted for the death of Louis XVI. As commissary from that assembly to the army in the Vendée, and afterward to that in the Pyrénées, he gave evidence of energy and talent. He took part with the Thermidoreans against Robespierre, and was sent on a third mission to the army of Rhin et Moselle. Having returned to Paris, he was on the 1st Prairial intrusted with the command of the troops to protect the convention against the rebels, but was unable to prevent their invading the hall of the assembly. On the 18th Vendémiaire, he was made an assistant to Barras in the defence of the convention, but had not much to do, owing to the appointment by his colleague of the young Gen. Bonaparte, who took all the responsibility on himself and saved the convention. Cavaignac was for a while a member of the council of 500. On retiring from that assembly, his reduced circumstances constrained him to accept several inferior offices. In 1806 he entered the service of Naples under Joseph, and was appointed councillor of state by his successor Murat. He returned to France in 1812, and was in 1815, during the Hundred Days, appointed prefect of the Somme. On the 2d restoration, being expelled from France as a regicide, he repaired to Brussels, where he lived obscurely. II. **ELTONORE LOUIS GODEFROY**, a French republican journalist, the elder son of the preceding, born at Paris in 1801, died May 5, 1845. He was one of the most popular leaders of the republican party during the restoration and the reign of Louis Philippe. He distinguished himself in the revolution of July, but, disappointed by the elevation of Louis Philippe to the throne, he took a more or less active part in the conspiracies for the overthrow of the new dynasty. He was several times arrested and arraigned before the tribunals, but generally evaded condemnation through his skilful defence, while winning great popularity by his chivalric and dignified bearing in all his trials. He was one of the founders of the *société des amis du peuple*, and on the dissolution of that association he was active in the more powerful organization of the *société des droits de l'homme*. After the troubles of 1834 he was arrested with several others, tried before a special court, and sentenced to prison. He was incarcerated at Ste. Pélagie, but succeeded in making his escape July 18, 1835, and retired to Belgium, where he spent nearly 6 years. In 1841 he returned to France, and became one of the editors and in fact the inspiring mind of the *Réforme*, the most violent of the opposition journals. He was the author of *Le cardinal Dubois, ou tout chemin mène à Rome*, and *Une tuerie de Cosaques*, which are remembered only on account of his political reputation. III. **LOUIS EUGÈNE**, a French general, and chief of the republic in 1848, 2d son of Jean Baptiste, born in Paris, Oct. 15, 1802, died at his country seat, Château Ourmes, near Flée, department of Sarthe, Oct. 28, 1857. He was educated at the polytechnic school, and entered the army as

sub-lieutenant of engineers, took part in the French expedition to the Morea, and was appointed to a captaincy in 1829. On the revolution of 1830, he was the first officer of his regiment to declare for the new order of things, but being soon dissatisfied with the tendencies of the government he entered the *association nationale*, an organization of the opposition, in consequence of which he was for a while discharged from active service. In 1832 he was sent to Africa, where he had to make his way by his own talents and prowess. Being intrusted in 1836 with the command of the fortress of Tlemcen, he held this advanced post for 3 years against the repeated assaults of the Arabs. When relieved in 1839 from his arduous task, his health having been impaired by incessant exertions, he asked to be placed on leave; he was then made a major. A few months later he returned to Africa, where his defence of Ocherchell was no less brilliant than that of Tlemcen. In 1840 he was promoted to a lieutenant-colonelcy, and then to the colonelcy of the Zouaves. Finally, in 1844, he was made brigadier-general and governor of the province of Oran. On the revolution of February, 1848, he was appointed governor-general of Algeria, and promoted to the rank of general of division. The same year he was elected to the constituent assembly by both the departments of Seine and Lot; the latter being the native place of his family, he gave it his preference, and was allowed to leave Algeria to take his seat as a representative. He reached Paris 2 days after the disturbances of May 15, and was immediately appointed minister of war, with the condition that he should bring to Paris a sufficient number of troops to protect the capital against any popular outbreak. In a few weeks 75,000 regular troops were gathered within the walls, while 190,000 national guards were ready to support them. All was ready for civil war, which broke out on the dissolution of the *ateliers nationaux*. On June 22 barricades were erected in the most central parts of the city. The executive committee of the constituent assembly advised that troops should be sent in all directions to anticipate hostile preparations; but Cavaignac refused, and concentrated his troops in order finally to bear on the principal points with irresistible force. The assembly having at last invested him with dictatorial powers, the struggle commenced in earnest June 23, at 11 o'clock, and lasted for 70 hours with scarcely an intermission. At last victory was secured to the government through the skilful measures of Cavaignac, the intrepidity of his fellow-generals, Bedeau, Lamoricière, Foucher, the firmness of the national guard, the courage of the regular troops, but above all, the exertions of the young *gardes mobiles*. On June 29 Cavaignac resigned his dictatorship, and the assembly unanimously elected him chief of the executive power. He was then the most popular man among the *bourgeoisie*; but he was disliked by the lower classes, and had, beside, drawn

upon himself the unrelenting hatred of several journalists, especially Émile de Girardin, who at once waged against him the most formidable warfare. Several propositions were made in the assembly to make him president for 4 years without recourse to an election; but the idea was contrary to his principles, and he rejected it. When the presidential election came on (Dec. 10), although Cavaignac had at his disposal all the government patronage, he was defeated by an immense majority. Out of 7,442,471 votes, Cavaignac received but 1,448,303, while Louis Napoleon had 5,584,520. Cavaignac bore his defeat with dignity and tranquillity. On Dec. 20 he resigned his power into the hands of the newly-elected president, and modestly returned to his seat in the assembly. He continued to take part in the proceedings of that body, speaking rarely, but with marked ability and effect. On the *coup d'état* of Dec. 1851, he was arrested and taken to the castle of Ham, his name being placed at the head of the list of the proscribed. Previous to this event he had been betrothed to Mlle. Odier, daughter of a wealthy banker of Paris; after the *coup d'état* and the ruin of the republican party, efforts were made to break off the match, but in vain; and the first kindly face which Cavaignac saw in the fortress of Ham, after his imprisonment, was that of the maiden who a few days later became his wife, the marriage taking place immediately after his release, when he was at his own request placed on the retired list of the army. He subsequently lived for a time in retirement in Belgium, and when he returned to France resided mainly at his country seat in the department of Sarthe. In 1852 he was elected to the legislative body, but refused to take the oath of allegiance to the emperor. In 1857 he was again chosen to the same office by the electors of the 8d district of Paris, as a kind of protest against the existing form of government, but again refused to take the oath. This was the last public act of his life. Grief and chagrin at the measures of the government and the suffering of thousands of his political friends condemned to exile and misery had long caused in his emotions which aggravated a disease of the heart, the germs of which had been contracted in Africa; and one morning, as he was leaving his house to visit a friend, he suddenly expired in the arms of an attendant without uttering a word. His devoted wife conveyed his remains to Paris, where they received the honors of a funeral procession in which many thousands of persons took part. He left an only son.

CAVAILLON, a French town on the river Durance, in the department of Vaucluse, and the arrondissement of Avignon; pop. 7,405. It has an active trade in raw silk, fruits, and preserves, and manufactories of vermicelli and macaroni. During the revolution its fortifications were destroyed. It was an ancient Roman town, but having been repeatedly pillaged by barbarians, and having suffered much from an earthquake in 1731, it has few remains of antiquity. The

ble of its ruins is a triumphal arch  
which have belonged to the Augustan  
The country round Cavaillon is justly  
the garden of the province.

CAVALCANTI, GUIDO, an Italian philoso-  
and poet, born in Florence in the early  
of the 18th century, died in 1800. Dante,  
was his friend, introduces Cavalcanti's father  
in *Inferno* into the regions of the condemned,  
account of his Epicurean philosophy. Guido  
distinguished for the lofty style of his  
poetry, which was composed for the most part  
sonnets and canzonets, the most celebrated  
of which are those dedicated to Mandetta, a  
whom he had met at Toulouse after his  
return from a pilgrimage to Compostella. Hav-  
ing married a daughter of the Ghibelline chief  
degli Uberti, he succeeded his father-in-  
law as head of that party. When the leaders of  
the Ghibellines were exiled by the citizens, Caval-  
canti was sent to Sarzana, where his health was  
much injured by the bad air, that he died soon  
after his return. His *Rime, edite ed inedite*,  
were published by Cacciaporri at Florence, in  
1813.

CAVALIER, JEAN, a leader of the Camisards  
among the Protestant dissenters in the Cevennes, born  
in 1679 at Ribaute, in Languedoc, died in  
1740, at Chelsea, a suburb of London.  
Son of a poor peasant, he was first a shep-  
herd, then a journeyman baker. Religious per-  
secution afterward forced him to leave his  
country, but after living a few months at Ge-  
neva, he secretly came back, and was foremost  
among the promoters of the insurrection of  
1702. He was at once a preacher and a sol-  
dier, and his talents, devotion, and prophetic  
gifts gave him an authority almost equal to that  
of the Camisard commander-in-chief. When  
Marshal Villars took the command of the royal  
troops, Cavalier had an interview with him at  
Nîmes, and agreed on terms of peace: the  
young chief was to be received into the king's  
service, with the rank of colonel and a hand-  
some pension; a regiment was to be raised  
among the Camisards, who were now to enjoy  
free exercise of their religion. This treaty  
did not suit the other chiefs or the people.  
Cavalier was immediately discarded by them,  
and departed for Paris attended by very few com-  
plices. There he was treated with contempt  
by the king; and having received secret ad-  
vice that he was to be put in prison, he made  
his escape to Switzerland, whence he went to  
Holland. Having entered the service of Eng-  
land, he organized a regiment of French re-  
fugees, whom he took to Spain to support the  
cause of Charles. At the battle of Almanza  
his regiment engaged a battalion of French  
troops, which fought with such fury that the  
greatest part of both corps were left dead on the  
battle field. Cavalier afterward joined the army  
of Prince Eugène, who entered Provence and  
besieged Toulon. After the peace of Utrecht,  
he repaired to England, where he was received  
with great favor, obtaining the rank of gen-

eral, and being appointed governor of the is-  
land of Jersey. An account of the "War in  
the Cevennes under Col. Cavalier" was publish-  
ed in English in 1726. Probably it was not  
written by Cavalier himself, and is of very  
little value. Eugène Sue has also furnished  
a work founded upon his life.

CAVALIER (Spanish *caballero*), a gen-  
tleman who fought on horseback, in the  
first instance, when the cavalry of European  
armies consisted wholly of the feudal landed  
aristocracy, with the gentlemen of their follow-  
ings. In its secondary sense, both in Spanish  
and English, the word came to signify abso-  
lutely, and without any reference to its deriva-  
tion or origin, a nobleman or gentleman of birth  
and breeding; and, as a yet further deduction,  
a gentleman of manners, accomplishments, and  
air. In the reign of Charles I. of England, the  
word, being used probably by the upper classes  
somewhat absolutely and hypercritically, so as  
to be offensive to their inferiors, received a par-  
ticular and pointed application, which it long  
continued to bear in England, as signifying one  
attached to the court and high church party,  
and thereafter a Jacobite or one attached to  
the Stuart family and favorable to their resto-  
ration, after the transfer of the crown to the  
houses of Nassau and Brunswick. It is commonly  
asserted that this usage of the word is to be  
ascribed, as is the case with many if not most  
political and party nicknames, to its introduc-  
tion by the opposite faction as a term of de-  
rision. This may be and probably is true in  
some degree; but it was certainly applied by  
gentlemen to themselves and to one another,  
before it was employed as a by-name of party  
reproach.

CAVALIERI, or CAVALLERI, BONAVENTURA,  
an Italian mathematician, born in Milan in  
1598, died in Bologna, Dec. 8, 1647. He studied  
mathematics at Pisa under B. Castelli, a disciple  
of Galileo, officiated as professor in Bologna, and  
was author of several mathematical works, the  
most prominent of which was entitled *Geome-  
tria Indivisibilium*, &c. Having expressed in  
this work some original ideas concerning the  
abstruse sciences, the Italians claim him to be  
the inventor of the infinitesimal calculus.

CAVALLINI, PIERRO, a Roman painter, who  
flourished in the latter part of the 18th and in  
the early part of the 14th century. He was the  
disciple of Giotto, and the first painter of the  
Roman school who was worthy of competing  
with the great Florentine masters. His most  
celebrated work, a picture of the "Crucifixion,"  
is at Assisi. Most of his other works are now  
destroyed.

CAVALLO, TIMOTHY, an electrician, born in  
Naples in March, 1749, was a resident of Lon-  
don during the greatest part of his life, and died  
there in Dec. 1809. He was the son of a Ne-  
apolitan physician, completed his education in  
the university of his native city, and went at  
an early age to England with a view of becom-  
ing a merchant; but devoting himself to the

period. Still it is certain that at least a couple of centuries before the country was conquered by the Persians, the Egyptians had a numerous cavalry, and the commander of this arm is more than once named among the most important officials of the court. It is very likely that the Egyptians became acquainted with cavalry during their war with the Assyrians; for on the Assyrian monuments horsemen are often delineated, and their use in war with Assyrian armies at a very early period is established beyond a doubt. With them, also, the saddle appears to have originated. In the older sculptures the soldier rides the bare back of the animal; at a later epoch we find a kind of pad or cushion introduced, and finally a high saddle similar to that now used all over the East. The Persians and Medians, at the time they appear in history, were a nation of horsemen. Though they retained the war chariot, and even left to it its ancient precedence over the younger arm of cavalry, yet the great numerical strength of the mounted men gave the latter an importance it had never possessed in any former service. The cavalry of the Assyrians, Egyptians, and Persians consisted of that kind which still prevails in the East, and which, up to very recent times,

Alexander the Great were more used to act in compact bodies in a mass. The Macedonians, however, were a match for them. With that preparation of the young nobility, and cavalry of high rank in their army. The cavalry of Alexander consisted of the Macedonian Thessalian nobility, with a few recruits recruited in Greece proper. It consisted of heavy horsemen—*cataphracts*—wearing helmet and breastplate, carrying a long spear. It usually charged in a compact column, an oblong or wedge-shaped column, also in line. The light cavalry, consisting of auxiliary troops, was of a different kind, and served like the *velites* of the Romans for outpost duty and skirmishing. The cavalry of the Persians (see B. C.) consisted of a mass of men, in which a decisive part was played by the heavy cavalry charging distance from the front, as soon as the heads of column of the infantry had passed the river. When they could deploy, the Persian cavalry would attack them and drove them headlong into the river. This manoeuvre,

and charged the Persians in flank. A battle ensued, but the Persian horsemen were massed in one line without reserves, and at last abandoned by the Asiatic part of their army, were ultimately routed.

The battle of Arbela (361 B. C.) was the most brilliant of the Macedonian cavalry. Alexander led the Macedonian horse, which formed the extreme right of his order of battle, while the Thessalian horse formed the left. The Persians tried to outflank him, but in the moment Alexander brought fresh men into the rear so as to overlap them in their flank, and at the same time left a gap behind in their left and centre. Into this gap Alexander's army at once dashed, separating their left from the remainder of the army, rolling it up, and pursuing it for a considerable distance.

Then, on being called upon to send reinforcements to his own menaced left, he rallied them in a very short time, and passing between the enemy's centre and the rear of his army, the enemy's centre fell upon the rear of his army.

The battle was thus gained, and Alexander from that day ranks among the greatest of cavalry generals of all times. And in the work, his cavalry pursued the enemy with such ardor that its advance guard stood the next day 75 miles in front of the battle-field. It is very curious

that the general principles of cavalry warfare are as well understood at that time as now. To attack infantry in the front, to attack cavalry principally on its flank, to follow up a victory by an inexorable pursuit of the broken ranks, these are among the first and most important rules that every modern cavalry officer should learn.

After Alexander's death we find the glory of that splendid cavalry of Greece and Rome. In Greece infantry again pre-eminently, in Asia and Egypt the mounted troops degenerated.—The Romans never had a cavalry of their own. What little cavalry they had was of an inferior breed, and they did not ride. But on the southern side of the Mediterranean a cavalry was formed, which was valued, but even outshone that of Alexander.

The Carthaginian generals, Hamilcar and Hannibal, had succeeded in forming, between the Numidian irregular horsemen, a body of regular cavalry, and thus created a cavalry which almost everywhere insured victory. The Berbers of north Africa, even to the present day, a nation of horsemen, are the best in the plains, and the splendid horses which carried Hannibal's swordsmen

through the deep masses of the Roman infantry with a rapidity and vehemence unknown to the French cavalry, the *chasseurs d'Afrique* are by them acknowledged to be the

best war-horse in existence. The Carthaginian infantry was far inferior to that of the Romans, even after it had been long trained by its two great chiefs; it would not have had the slightest chance against the Roman legions, had it not been for the assistance of that cavalry which alone made it possible for Hannibal to hold out 16 years in Italy; and when this cavalry had been worn out by the wear and tear of so many campaigns, not by the sword of the enemy, there was no longer a place in Italy for him. Hannibal's battles have that in common with those of Frederic the Great, that most of them were won by cavalry over first-rate infantry; and, indeed, at no other time has cavalry performed such glorious deeds as under those two great commanders. From what nation, and upon what tactical principles, Hamilcar and Hannibal formed their regular cavalry, we are not precisely informed. But as their Numidian light horse are always clearly distinguished from the heavy or regular cavalry, we may conclude that the latter was not composed of Berber tribes. There were very likely many foreign mercenaries and some Carthaginians; the great mass, however, most probably consisted of Spaniards, as it was formed in their country, and as even in Cæsar's time Spanish horsemen were attached to most Roman armies. Hannibal being well acquainted with Greek civilization, and Greek mercenaries and soldiers of fortune having before his time served under the Carthaginian standards, there can scarcely be a doubt that the organization of the Grecian and Macedonian heavy cavalry served as the basis for that of the Carthaginian. The very first encounter in Italy settled the question of the superiority of the Carthaginian horse. At the Ticinus (218 B. C.), the Roman consul Publius Scipio, while reconnoitring with his cavalry and light infantry, met with the Carthaginian cavalry led by Hannibal on a similar errand. Hannibal at once attacked. The Roman light infantry stood in first line, the cavalry formed the second. The Carthaginian heavy horse charged the infantry, dispersed it, and then fell at once on the Roman cavalry in front, while the Numidian irregulars charged their flank and rear. The battle was short. The Romans fought bravely, but they had no chance whatever. They could not ride; their own horses vanquished them; frightened by the flight of the Roman skirmishers, who were driven in upon them and sought shelter between them, they threw off many of their riders and broke up the formation. Other troopers, not trusting to their horsemanship, wisely dismounted and attempted to fight as infantry. But already the Carthaginian cuirassiers were in the midst of them, while the inevitable Numidians galloped round the confused mass, cutting down every fugitive who detached himself from it. The loss of the Romans was considerable, and Publius Scipio himself was wounded. At the Trebia, Hannibal succeeded in enticing the Romans to cross that river, so as to fight with this

40,000 infantry and 10,000 cavalry. The cavalry of Latium formed the Roman right wing, leaning on the river Aufidus; that of the allied Italians stood on the left, while the infantry formed the centre. Hannibal, too, placed his infantry in the centre, the Celtic and Spanish levies again forming the wings, while between them, a little further back, stood his African infantry, now equipped and organized on the Roman system. Of his cavalry, he placed the Numidians on the right wing, where the open plain permitted them, by their superior mobility and rapidity, to evade the charges of the Italian heavy horse opposed to them; while the whole of the heavy cavalry, under Hasdrubal, was stationed on the left, close to the river. On the Roman left, the Numidians gave the Italian cavalry plenty to do, but from their very nature as irregular horse could not break up their close array by regular charges. In the centre, the Roman infantry soon drove back the Celts and Spaniards, and then formed into a wedge-shaped column in order to attack the African infantry. These, however, wheeled inward, and charging the unwieldy mass in line, broke its impetus; and there the battle, now, became a standing fight. But Hasdrubal's heavy

line empire, under Justinian, was on a comparatively respectable level in the battle of Capua in A. D. 552. Narses is reported to have defeated the invaders of Italy principally by his arm.—The establishment of a new army in western Europe, of a conquering Teutonic origin, led to a new era in the development of cavalry. The nobility took the mounted service, under the name of men-at-arms (*gens d'armes*), for the most part of horse of the heaviest description, not only the riders but also the horses were covered with defensive armor. It was at the battle at which such cavalry first appeared that at Poitiers, where Charles the Great beat back the torrent of Arab and Frankish knighthood, under the command of Aquitania, broke through the ranks of the enemy and took their camp. But such a mode of fighting was not fit for pursuit; and the Arabs, under shelter of their horses, retired with this battle demonstrated the value of a massive but unwarlike arm. The West fought the battle of Tours with varied success. (The battle of Tours was a decisive victory for the Franks over the Muslims, but the text is cut off.)

ly destroyed; neither they nor their horses could stand the climate, the immensely long marches, and the want of proper food and forage. These crusades were followed by a fresh irruption of eastern horsemen into Europe, that of the Mongols. Having overrun Russia, and the provinces of Poland, they were met at Wahlstatt in Silesia, in 1241, by a combined Polish and German army. After a long struggle, the Asiatics defeated the worn-out steel-clad knights, but the victory was so dearly bought that it broke the power of the invaders. The Mongols advanced no further, and soon, by divisions among themselves, ceased to be dangerous, and were driven back. During the whole of the middle ages, cavalry remained the chief arm of all armies: with the eastern nations the light irregular horse had always held that rank; with those of western Europe, the heavy regular cavalry formed by the knighthood was in this period the arm which decided every battle. This preëminence of the mounted arm was not so much caused by its own excellence, for the irregulars of the East were incapable of orderly fight, and the regulars of the West were clumsy beyond belief in their movements; it was principally caused by the bad quality of the infantry. Asiatics as well as Europeans held that arm in contempt; it was composed of those who could not afford to appear mounted, principally of slaves or serfs. There was no proper organization for it; without defensive armor, with a pike and sword for its sole weapons, it might now and then by its deep formation withstand the furious but disorderly charges of eastern horsemen; but it was resistlessly ridden over by the invulnerable men-at-arms of the West. The only exception was formed by the English infantry, which derived its strength from its formidable weapon, the long-bow. The numerical proportion of the European cavalry of these times to the remainder of the army was certainly not as strong as it was a few centuries later, nor even as it is now. Knights were not so exceedingly numerous, and in many large battles we find that not more than 800 or 1,000 of them were present. But they were generally sufficient to dispose of any number of foot soldiers, as soon as they had succeeded in driving from the field the enemy's men-at-arms. The general mode of fighting of these men-at-arms was in line, in single rank, the rear rank being formed by the esquires, who wore, generally speaking, a less complete and heavy suit of armor. These lines, once in the midst of the enemy, soon dissolved themselves into single combatants, and finished the battle by sheer hand-to-hand fighting. Subsequently, when firearms began to come into use, deep masses were formed, generally squares; but then the days of chivalry were numbered. During the 15th century, not only was artillery introduced into the field of battle, while part of the infantry, the skirmishers of those times, were armed

with muskets, but a general change took place in the character of infantry. This arm began to be formed by the enlistment of mercenaries who made a profession of military service. The German *Landsknechte* and the Swiss were such professional soldiers, and they very soon introduced more regular formations and tactical movements. The ancient Doric and Macedonian phalanx was, in a manner, revived; a helmet and a breastplate somewhat protected the men against the lance and sword of the cavalry; and when, at Novara (1513), the Swiss infantry drove the French knighthood actually from the field, there was no further use for such valiant but unwieldy horsemen. Accordingly, after the insurrection of the Netherlands against Spain, we find a new class of cavalry, the German *Reiters* (*reîtres* of the French), raised by voluntary enlistment, like the infantry, and armed with helmet and breastplate, sword and pistols. They were fully as heavy as the modern cuirassiers, yet far lighter than the knights. They soon proved their superiority over the heavy men-at-arms. These now disappear, and with them the lance; the sword and short firearms now form the general armature for cavalry. About the same time (end of the 16th century) the hybrid arm of dragoons was introduced, first in France, then in the other countries of Europe. Armed with muskets, they were intended to fight, according to circumstances, either as infantry or as cavalry. A similar corps had been formed by Alexander the Great under the name of the *dimachæ*, but it had not yet been imitated. The dragoons of the 16th century had a longer existence, but toward the middle of the 18th century they had everywhere lost their hybrid character, except in name, and were generally used as cavalry. The most important feature in their formation was that they were the first body of regular cavalry which was completely deprived of defensive armor. The creation of real hybrid dragoons was again attempted, on a large scale, by the emperor Nicholas of Russia; but it was soon proved that, before the enemy, they must always be used as cavalry, and consequently Alexander II. very soon reduced them to simple cavalry, with no more pretensions to dismounted service than hussars or cuirassiers. Maurice of Orange, the great Dutch commander, formed his *Reiters* for the first time in something like our modern tactical organization. He taught them to execute charges and evolutions in separate bodies, and in more than one line; to wheel, break off, form column and line, and change front, without disorder, and in separate squadrons and troops. Thus a cavalry fight was no longer decided by one charge of the whole mass, but by the successive charges of separate squadrons and lines supporting each other. His cavalry was formed generally 5 deep. In other armies it fought in deep bodies, and where a line formation was adopted it was still from 5 to 8 deep. The 17th century, having completely done away with the costly men-at-

arms, increased the numerical strength of cavalry to an enormous extent. At no other period was there so large a proportion of that arm in every army. In the 80 years' war from  $\frac{1}{2}$  to nearly  $\frac{1}{4}$  of each army was generally composed of cavalry; in single instances there were 2 horsemen to 1 foot soldier. Gustavus Adolphus stands at the head of cavalry commanders of this period. His mounted troops consisted of cuirassiers and dragoons, the latter fighting almost always as cavalry. His cuirassiers, too, were much lighter than those of the emperor, and soon proved their incontestable superiority. The Swedish cavalry were formed 8 deep; their orders were, contrary to the usage of the cuirassiers of most armies, whose chief arm was the pistol, not to lose time in firing, but to charge the enemy sword in hand. At this period the cavalry, which during the middle ages had generally been placed in the centre, was again placed, as in antiquity, on the wings of the army, where it was formed in 8 lines. In England, the civil war gave rise to 2 distinguished cavalry leaders. Prince Rupert, on the royalist side, had as much "dash" in him as any cavalry general, but he was almost always carried too far, lost his cavalry out of hand, and was himself so taken up with what was immediately before him, that the general always disappeared in the "bold dragoon." Cromwell, on the other hand, with quite as much dash where it was required, was a far better general; he kept his men well in hand, always held back a reserve for unforeseen events and decisive movements, knew how to manœuvre, and thus proved generally victorious over his inconsiderate opponent. He won the battles of Marston Moor and Naseby by his cavalry alone.—With most armies the use of the firearm still remained the chief employment of cavalry in battle, the Swedes and English alone excepted. In France, Prussia, and Austria, cavalry was drilled to use the carbine exactly as infantry used the musket. They fired on horseback, the line standing still all the while, by files, platoons, ranks, &c.; and when a movement for a charge was made, the line advanced at a trot, pulled up at a short distance from the enemy, gave a volley, drew swords, and then charged. The effective fire of the long lines of infantry had shaken all confidence in the charge of a cavalry which was no longer protected by armor; consequently, riding was neglected, no movements could be executed at a quick pace, and even at a slow pace accidents happened by the score to both men and horses. The drill was mostly dismounted work, and their officers had no idea whatever of the way of handling cavalry in battle. The French, it is true, sometimes charged sword in hand, and Charles XII. of Sweden, true to his national tradition, always charged full speed without firing, dispersing cavalry and infantry, and sometimes even taking field works of a weak profile. But it was reserved for Frederic the Great and his great cavalry commander, Seydlitz, to revolutionize the mounted service, and

to raise it. The Prussian horses, drill, father had been instant at the first Silesian campaign entirely and dismounted background, evolutions, speed, all with cavalry officers into perfect handy and excellent well exercised men were to ground, across back, were firing at all lines of the "Every squadron charge, is to and no com troops fire on the generals this. As the quick trot, well closed; majesty is broken." "always present but 2 things to charge speed and These passed sufficiently tried out in admirably by his cuirassier troops of the of charge, of flank attack forming after equalled the war. The henfriedberg goons, 10 sq wing of the ions, took 60 prisoners. infantry had with 86 sq cavalry from Russian infantry great slaughter selsdorf, Leu eric owed to When the French the Austrian but not so latter nation ized by the the war the less. When met by the Prussians, and A

most uniformly beaten. The cavalry, to cope with such opponents, was always in reserve until a few years' campaign improved them. Since 1795 and after division of infantry had cavalry as a bill, at Würzburg, the whole of the cavalry was defeated by 59 Austrian (1796). When Napoleon took the affairs in France, he did his best to improve French cavalry. He found about the best that could be met with. As a nation are decidedly the worst horsemen and their horses, good for draught, but adapted for the saddle. Napoleon was but an indifferent rider, and neglecting in others. Still he made great use, and after the camp of Boulogne, in great part, mounted on German horses, was no despicable adversary. Guns of 1805 and 1806-'7 allowed him to absorb almost all the horses of the old Prussian armies, and beside, reinforced his army by the excellent cavalry of the Rhine and the grand army. Thus were formed those masses of horsemen with which Napoleon won in 1809, 1812, and the latter part of the war, though generally designated as the cuirassiers, were in great part composed of old Polish. The cuirass, which had long been done away with in the French army before the revolution, was re-introduced as a portion of the heavy cavalry by Napoleon. In other respects the organization remained nearly the same, with his Polish auxiliaries he received masses of light horse, armed with the same arms and equipment of which were used in other armies. But in the use of cavalry he introduced a complete reorganization to the system of composing an army corps of all 8 arms, a portion of light cavalry was attached to each army corps; but the mass of the army, especially all the heavy horse, were held in reserve for the purpose of striking at the moment a great decisive blow, if need, of covering the retreat of the army masses of cavalry, suddenly appearing at a given point of the battle-field, have been decisive; still, they never gained great successes as the horsemen of Frederick the Great. The cause of this is to be found partly in the changed tactics of infantry, by selecting chiefly broken ground for its operations, and always receiving the enemy in square, made it more difficult for the cavalry to achieve such great victories as the Prussian horsemen had obtained over the infantry lines of their opponents. It is so certain that Napoleon's cavalry was equal to that of Frederick the Great, that Napoleon's cavalry tactics were not in any instance an improvement upon those of Frederick. The indifferent riding of the French compelled them to charge at a com-

paratively slow pace, at a trot or a collected canter; there are but few instances where they charged at a gallop. Their great bravery and close ranks made up often enough for the curtailed impetus, but still their charge was not what would now be considered good. The old system of receiving hostile cavalry standing, carbine in hand, was in very many cases retained by the French cavalry, and in every such instance were they defeated. The last example of this happened at Danigkow (April 5, 1813), where about 1,200 French cavalry thus awaited a charge of 400 Prussians, and were completely beaten in spite of their numbers. As to Napoleon's tactics, the use of great masses of cavalry with him became such a fixed rule, that not only was the divisional cavalry weakened so as to be completely useless, but also in the employment of these masses he often neglected that successive engagement of his forces which is one of the principal points in modern tactics, and which is even more applicable to cavalry than to infantry. He introduced the cavalry charge in column, and even formed whole cavalry corps into one monster column, in such formations that the extrication of a single squadron or regiment became an utter impossibility, and that any attempt at deploying was entirely out of the question. His cavalry generals, too, were not up to the mark, and even the most brilliant of them, Murat, would have cut but a sorry figure if opposed to a Seydlitz. During the wars of 1813, '14, and '15, cavalry tactics had decidedly improved on the part of Napoleon's opponents. Though to a great extent following Napoleon's system of holding cavalry in reserve in large masses, and therefore very often keeping the greater portion of the cavalry entirely out of an action, still in many instances a return to the tactics of Frederick was attempted. In the Prussian army the old spirit was revived. Blücher was the first to use his cavalry more boldly, and generally with success. The ambushade of Haynau (1813), where 20 Prussian squadrons rode down 8 French battalions and took 18 guns, marks a turning point in the modern history of cavalry, and forms a favorable contrast to the tactics of Lützen, where the allies held 18,000 horse entirely in reserve until the battle was lost, although a more favorable cavalry ground could not be found.—The English had never adopted the system of forming large masses of cavalry, and had therefore many successes, although Napier himself admits that their cavalry was not so good at that time as that of the French. At Waterloo (where, by the way, the French cuirassiers for once charged at full speed), the English cavalry was admirably handled and generally successful, except where it followed its national weakness of getting out of hand. Since the peace of 1815, Napoleon's tactics, though still preserved in the regulations of most armies, have again made room for those of Frederick. Riding is better attended to, though still not at all to the

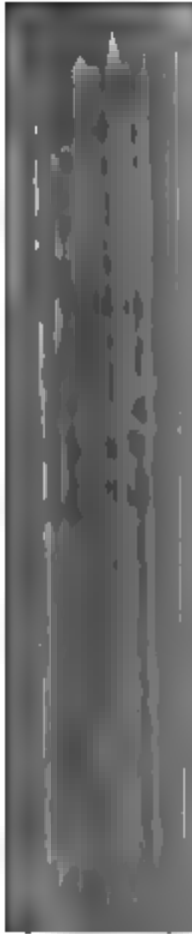

the lancers mostly in the Polish provinces. The recruiting of the horses, however, deserves especial notice. In England, where the whole cavalry does not require in time of war above 10,000 horses, the government finds no difficulty in buying them; but in order to insure to the service the benefit of horses not worked till nearly 5 years old, 8-year-old colts, mostly Yorkshire bred, are bought and kept at government expense in depots till they are fit to be used. The price paid for the colts (£20 to £25), and the abundance of good horses in the country, make the British cavalry certainly the best mounted in the world. In Russia a similar abundance of horses exists, though the breed is inferior to the English. The remount officers buy the horses by wholesale in the southern and western provinces of the empire, mostly from Jewish dealers; they re-sell those that are unfit, and hand over to the various regiments such as are of its color (all horses being of the same color in a Russian regiment). The colonel is considered as proprietor of the horses; for a round sum paid to him he has to keep the regiment well mounted. The horses are expected to last 8 years. Formerly they were taken from the large

horses, and the best of the *chasseurs d'Afrique*, — with them, but the ot get any. Thus in case of a French are compelled to buy in England, but mostly in n where they do not get the b though each horse costs t Many condemned horses fr regiments find their way in the French, and altogether the F *chasseurs d'Afrique* excepted, mounted in Europe.—Cavalry 2 kinds: heavy and light. The character of the 2 is in and powerful horses c with small, active, ab mer in a charge act le greater weight; the l and impetuosity of over far more fit mishing, for which heavy of neither handy nor intel far the distinction is fancy, and the costumes, have and varieties, to

preferable for thrusts, the second for cuts. The question as to the advantages of the lance over the sword is still under discussion. For close encounter the sword is undoubtedly preferable; and in a charge the lance, unless too long and heavy to be wielded, can scarcely act at all, but in the pursuit of broken cavalry it is found most effective. Of nations of horsemen, almost all trust to the sword; even the Cossack abandons his lance when he has to fight against the expert swordsmen of Circassia. The pistol is useless except for a signal shot; the carbine is not very effective, even if rifled, and never will be of much real use until a breech-loading one is adopted; the revolver in skilful hands is a formidable weapon for close encounter; still the queen of weapons for cavalry is a good, sharp, handy sword.—Beside the saddle, bridle, and armed rider, the cavalry horse has to carry a valise with reserve clothing, camp utensils, grooming tackle, and in a campaign also food for the rider and forage for itself. The sum total of this burden varies in different services and classes of cavalry, between 250 and 300 lbs. for the heavy marching order, a weight which will appear enormous when compared with what private saddle horses have to carry. This overweighting the horses is the weakest point of all cavalry. Great reforms are everywhere required in this respect. The weight of the men and accoutrements can and must be reduced, but as long as the present system lasts, this drag upon the horses is always to be taken into account whenever we judge of the capabilities of exertion and endurance of cavalry. Heavy cavalry, composed of strong but, if possible, comparatively light men, on strong horses, must act principally by the force of a well-closed, solid charge. This requires power, endurance, and a certain physical weight, though not as much as would render it unwieldy. There must be speed in its movements, but no more than is compatible with the highest degree of order. Once formed for the attack, it must chiefly ride straight forward; but whatever comes in its path must be swept away by its charge. The riders need not be, individually, as good horsemen as those of light cavalry; but they must have full command over their horses, and be accustomed to ride straight forward and in a well-closed mass. Their horses, in consequence, must be less sensible to the leg, nor should they have their haunches too much under them; they should step out well in their trot, and be accustomed to keep well together in a good, long hand gallop. Light cavalry, on the contrary, with nimbler men and quicker horses, has to act by its rapidity and ubiquity. What it lacks in weight must be made up by speed and activity. It will charge with the greatest vehemence; but when preferable, it will seemingly fly in order to fall upon the enemy's flank by a sudden change of front. Its superior speed and fitness for single combat render it peculiarly fit for pursuit. Its

chiefs require a quicker eye and a greater presence of mind than those of heavy horse. The men must be, individually, better horsemen; they must have their horses perfectly under control, start from a stand into a full gallop, and again stop in an instant; turn quick, and leap well; the horses should be hardy and quick, light in the mouth, and obedient to the leg, handy at turning, and especially broken in for working at a canter, having their haunches well under them. Beside rapid flank and rear attacks, ambuscades, and pursuit, the light cavalry has to do the greater part of the outpost and patrolling duty for the whole army; aptness for single combat, the foundation of which is good horsemanship, is therefore one of its principal requirements. In line, the men ride less close together, so as to be always prepared for changes of front and other evolutions.—The English have nominally 13 light and 13 heavy regiments (dragoons, hussars, lancers; the 2 regiments of life-guards alone are cuirassiers); but in reality all their cavalry, by composition and training, are heavy cavalry, and little different in the size of men and horses. For real light cavalry service they have always used foreign troops—Germans in Europe, native irregulars in India. The French have 8 kinds: light cavalry hussars and chasseurs, 174 squadrons; line cavalry, lancers and dragoons, 120 squadrons; reserve cavalry, 78 squadrons, cuirassiers and carabineers. Austria has 96 squadrons of heavy cavalry, dragoons and cuirassiers; and 192 squadrons of light, hussars and lancers. Prussia has, of the line, 80 squadrons of heavy horse, cuirassiers and lancers; and 72 squadrons of light horse, dragoons and hussars; to which may be added, in case of war, 136 squadrons of lancers of the first levy of the landwehr. The second levy of the landwehr cavalry will scarcely ever be formed separately. The Russian cavalry consists of 160 heavy squadrons, cuirassiers and dragoons; and 304 light squadrons, hussars and lancers. The formation of the dragoon corps for alternate mounted and infantry duty has been abandoned, and the dragoons incorporated with the heavy cavalry. The real light cavalry of the Russians, however, are the Cossacks, of whom they always have more than enough for all the outpost, reconnoitring, and irregular duties of their armies. In the U. S. army there are 2 regiments of dragoons, 1 of mounted riflemen, and 2 styled cavalry; all of which regiments, it has been recommended, should be called regiments of cavalry. The U. S. cavalry is really a mounted infantry.—The tactical unity in cavalry is the squadron, comprising as many men as the voice and immediate authority of one commander can control during evolutions. The strength of a squadron varies from 100 men (in England) to 200 men (in France); those of the other armies also being within these limits. Four, 6, 8, or 10 squadrons form a regiment. The weakest regiments are the English (400 to 480 men); the strongest the Austrian light horse (1,600

in battle is eminently a hand-to-hand encounter; its fire is of subordinate importance; steel—either sword or lance—is its chief weapon; and all cavalry action is concentrated in the charge. Thus the charge is the criterion for all movements, evolutions, and positions of cavalry. Whatever obstructs the facility of charging is faulty. The impetus of the charge is produced by concentrating the highest effort both of man and horse into its crowning moment, the moment of actual contact with the enemy. In order to effect this, it is necessary to approach the enemy with a gradually increasing velocity, so that the horses are put to their full speed at a short distance from the enemy only. Now the execution of such a charge is about the most difficult matter that can be asked from cavalry. It is extremely difficult to preserve perfect order and solidity in an advance at increasing pace, especially if there is much not quite level ground to go over. The difficulty and importance of riding straight forward is here shown; for unless every rider rides straight to his point, there arises a pressure in the ranks, which is soon rolled back from the center to the flanks and from the flanks to the

at least of the victorious troop has up its tactical formation, in order the sword the harvest of victory; successful charge at once decides but unless followed up by pursuit combat, the victory would be fruitless. It is this immense pressure the party which has preserved its compactness and formation, over the other, which explains the impotence of irregular cavalry, be it ever so numerous, to defeat regular cavalry. I doubt that so far as individual swordsmanship is concerned cavalry ever approached the irrepressible nations of horse-warriors of the East; the very worst of European regulars has always defeated them in the field. The defeat of the Huns at Chalons (451) and the Sepoy mutiny of 1857, there is not a single instance where the splendid but irregular men of the East have broken a strong regular cavalry in an actual charge. A regular swarm, charging without compactness, cannot make any impression on the solid, rapidly moving mass.

nans. Of this there is no better example than of Napoleon's dragoons in Egypt, where the worst regular cavalry then known, which defeated in every instance the best of irregular horsemen, the Mamelukes. Napoleon said of them, 2 Mamelukes were equal to 3 Frenchmen; 100 Frenchmen were a match for 100 Mamelukes; 200 Frenchmen generally beat 300 Mamelukes; 300 Frenchmen in every instance defeated 400 Mamelukes. However great may be the advantage in a charge of that body of cavalry preserves its tactical formation, it is not even this body must, after the success of the charge, be comparatively disordered. The point of the charge is not equally decisive; many men are irretrievably lost in single combat or pursuit; and it is only a small portion, mostly belonging to the second rank, which remains in the line. This is the most dangerous defect of cavalry; a very small body of fresh troops thrown upon it, would snatch the victory from the victors. To rally quickly after a charge is the criterion of a really good cavalry, and at this point that not only young but also experienced and brave troops are required. The British cavalry, riding the most difficult ground, are especially apt to get out of order. They have almost everywhere suffered setbacks (e. g., at Waterloo and Balaklava). The rally, on the rally being sounded, is generally in some divisions or squadrons, specially regulated regulations designated for this service. The mass of the troops re-form to be able to meet emergencies. For the disorganization of the victors, after a charge, is in itself enough to always keep a reserve in hand, which may be launched in case of failure in any instance; and thus it is that the first principle of cavalry tactics has always been, never to expose more than a portion of the disposable force at one time. This general application of the principle explains the variable nature of large battles, where the tide of victory ebbs and flows, either party being beaten until the last disposable reserves are thrown into power of their unbroken order to bear down upon the disordered, surging mass, and decide the battle.

Another very important circumstance is the ground. No arm is so much connected with the ground as cavalry. Heavy, deep ground breaks the gallop into a slow canter; a single horseman would clear it, but a mass of men, looking at it, may break the order and the line; and an obstacle easy to pass on foot will bring down animals which have been trotted and galloped about with freedom early morning. Again, an obstacle, by stopping the advance and change of front and formation, may bring the whole line within reach of the enemy's muskets. An example of how cavalry could not be made, was Murat's great defeat at the battle of Leipsic. He formed 14,000 men into one deep mass, and advanced

on the Russian infantry which had just been repulsed in an attack on the village of Wachau. The French horse approached at a trot; about 600 or 800 yards from the allied infantry they broke into a canter; in the deep ground the horses soon got fatigued, and the impulse of the charge was spent by the time they reached the squares. Only a few battalions which had suffered severely were ridden over. Passing round the other squares, the mass galloped on through the second line of infantry, without doing any harm, and finally arrived at a line of ponds and morasses which put a stop to their progress. The horses were completely blown, the men in disorder, the regiments mixed and uncontrollable; in this state two Prussian regiments and the Cossacks of the guard, in all less than 2,000 men, surprised their flanks and drove them all pell mell back again. In this instance there was neither a reserve for unforeseen emergencies, nor any proper regard for pace and distance; the result was defeat.—The charge may be made in various formations. Tacticians distinguish the charge *en muraille*, when the squadrons of the charging line have none or but very small intervals between each other; the charge with intervals, where there are from 10 to 20 yards from squadron to squadron; the charge *en échelon*, where the successive squadrons break off one after the other from one wing, and thus reach the enemy not simultaneously but in succession, which form may be much strengthened by a squadron in open column on the outward rear of the squadron forming the first *échelon*; finally, the charge in column. This last is essentially opposed to the whole of the former modes of charging, which are all of them but modifications of the line attack. The line was the general and fundamental form of all cavalry charges up to Napoleon. In the whole of the 18th century, we find cavalry charging in column in one case only, i. e. when it had to break through a surrounding enemy. But Napoleon, whose cavalry was composed of brave men but bad riders, had to make up for the tactical imperfections of his mounted troops by some new contrivance. He began to send his cavalry to the charge in deep columns, thus forcing the front ranks to ride forward, and throwing at once a far greater number of horsemen upon the selected point of attack than could have been done by a line attack. The desire of acting with masses, during the campaigns succeeding that of 1807, became with Napoleon a sort of monomania. He invented formations of columns which were perfectly monstrous, and which, happening to be successful in 1809, were adhered to in the later campaigns, and helped to lose him many a battle. He formed columns of whole divisions either of infantry or of cavalry, by ranging deployed battalions and regiments one behind the other. This was first tried with cavalry at Eckmühl, in 1809, where 10 regiments of cuirassiers charged in column, 2 regiments deployed in front, 4 similar lines following at distances of

is made in several lines at charging intervals, supporting and relieving each other during a prolonged engagement. Napoleon, too, was the first to form his cavalry into masses of several divisions, called corps of cavalry. As a means of simplifying the transmission of commands in a large army, such an organization of the reserve cavalry is eminently necessary; but when maintained on the field of battle, when these corps had to act in a body, it has never produced any adequate results. In fact, it was one of the main causes of that faulty formation of monster columns which we have already mentioned. In the present European armies, the cavalry corps is generally retained, and in the Prussian, Russian, and Austrian services, there are even established normal formations and general rules for the action of such a corps on the field of battle, all of which are based on the formation of a first and second line and a reserve, together with indications for the placing of the horse artillery attached to such a body.—We have hitherto spoken of the action of cavalry so far only as it is directed against cavalry. But one of the principal purposes for which this arm is used in battle, in fact its principal use now-a-days, is its action against infantry. We have seen that in

his men on such infantry. At Waterloo, the reserve cavalry on Wellington's own flank broke the English and German squares. These troops, sheltered a good deal by the crest of the ridge, had suffered very little in the preceding cannonade, and were as good as intact. Such charges, adapted for the last stage of a battle, when the infantry has been a good deal exhausted both by actual engagement and by passivity under a concentrated fire. And in such cases they act decisively, as at Borodino and Ligny, especially when the infantry is broken, as in both these cases, by infantry. We cannot enter here into the details of the action in which cavalry may be called upon to act, as on outpost, patrolling, and escorting. A few words on the general tactics of cavalry, however, may find a place. In the present day, as more and more become the rule, the manoeuvres of the cavalry are necessarily more or less subordinated to the former. And as modern tactics are based upon the admixture and mutual support of all arms, it follows that for at least the cavalry, all independent action

by way independently. The cavalry of the mass of the cavalry with the army, the same subordinate position toward the infantry of the army as the divisional does toward the infantry division to which it belongs. Accordingly, the reserve will be held in hand till a favorable opportunity for a great blow offers itself, either to a grand infantry or cavalry attack of the reserve or to execute a charge of its own of a similar nature. From what has been stated it will be evident that the proper use of the reserve of cavalry is generally during the latter stages of a great battle; but then it may be that it has been decisive. Such immense successes as Seydlitz obtained with his horse are out of the question now; but still, most battles of modern times have been very much influenced by the part cavalry has played.

But the great importance of cavalry is in the pursuit. Infantry supported by artillery is at despair against cavalry so long as it keeps its order and steadiness; but once broken, no matter by what cause, it is a prey to the enemy.

Well-ordered men that are launched against the enemy are no running away from the horses; in difficult ground, good horsemen can find their way; and an energetic pursuit of the enemy by cavalry is always the best and the surest way to secure the full fruits of the victory.

Thus, whatever supremacy in battles has been gained by infantry, cavalry still remains an indispensable arm, and will always be so; and now, as heretofore, no army can fight the lists with a fair chance of success unless it has a cavalry that can both ride and fight.

CAVAN, the southernmost county of the province of Ulster, Ireland; area, 747 sq. m.; population, 1851, 174,071. The soil is wet and fertile, but with drainage it is rendered productive. The mountainous districts, which inconsiderable part of the county, are rich in coal, iron, lead, and copper have been discovered; marl, fuller's earth, potter's and brick earth are always plentiful. The linen trade is in decay in Cavan, but not at present to any extent. Cavan was anciently called *Brenny*, and was part of the territory of the Irish chief, the seduction of which by Dermot MacMurrough was the cause of the English invasion. It was made shire-ground toward the close of the 12th century. The county was divided into 5 baronies among the native possessors, 5 baronies among the lot of the O'Reilly family. The 5 having forfeited their possessions by the 1st at the beginning of the 17th century, reverted to the British crown. It is now divided into 8 baronies, and returns 2 members to the British parliament.—The county town, Cavan, is on the Dublin and Galway railway, 85½ m. from the former city. 1851, 8,254, beside several thousand in houses and other public establishments. It has quarter sessions, annual fairs, and a

weekly market, are held in the town. It contains a fine parish church, Presbyterian and Methodist meeting houses, a fever hospital, an infirmary, a royal endowed school, a county gaol and court-house, barracks, and a public pleasure-ground, bequeathed to the town by the late Lady Fernham.

CAVANAS, or CABANAS, a port of Cuba, on the N. W. coast of the island, 88 m. S. W. of Havana; lat. 28° 5' N., long. 82° 55' W. It has a fine deep bay, capable of containing 100 vessels, and is defended by a battery of 5 guns, having in its centre a martello tower, with 1 gun. The entrance to the bay lies between 2 extensive reefs. Some of the most celebrated specimens of Havana cigars bear the name of Cabanas.

CAVANILLES, ANTONIO JOSÉ, a Spanish naturalist, born at Valencia, Jan. 16, 1745, died in Madrid, May, 1804. Educated among the Jesuits, and having embraced the ecclesiastical profession, he was chosen tutor to the sons of the duke del Infantado, Spanish ambassador in France, and accompanied them to Paris, where he remained for 12 years. He became acquainted with the botanist Jussieu, and devoting his attention to the study of botany, he officiated, after his return to Madrid, from 1801 to the time of his death, as keeper of the royal gardens. His works are numerous; among them are "Elementary Principles of Botany;" a "Botanical Dissertation on the Sida, and other Plants having an affinity with it," 2 vols. 4to. with plates; and a "History of the Kingdom of Valencia," 2 vols. 8vo.

CAVATINA, in music, a short air without a repeat, often inserted in recitative for the purpose of affording an effective relief.

CAVE, EDWARD, an English printer and bookseller, born at Newton, Warwickshire, Feb. 29, 1691, died Jan. 10, 1754. He is chiefly known as the founder of the "Gentleman's Magazine," and as the friend of Dr. Johnson, who attended his death-bed, and wrote his life. The shop in which he did business still stands at St. John's gate, Clerkenwell, London.—WILLIAM, an English scholar and divine, born at Pickwell, Leicestershire, Dec. 30, 1637, died at Windsor in Aug. 1718. He was educated for the ministry at Cambridge, and subsequently held several cures. He was chaplain to Charles II., who made him canon of Windsor. Having selected as his residence the quiet vicarage of Isleworth, Middlesex, he devoted his life to researches into the history of the church. He produced a great number of works, the most important of which are his "Lives of the Fathers" (*Ecclesiastici*), "Lives of the Apostles," and "Primitive Christianity." His style is concise, simple, and easy, and his sentiments so liberal that he has been accused of Socinianism. A monument in Islington church marks his burial place.

CAVE, or CAVERN, a hollow place under ground, generally with an opening on the surface, or in the face of a rock or hill. The former term is sometimes applied to an artificial

at this city in some countries. The ancient city of Petra consists of artificial caves cut in the sandstone rock, which might have served as dwellings. We read in Genesis xix. that Lot "dwelt in a cave, he and his two daughters." The practice of burying the dead in caves seems to have been the origin of catacombs. Nearly all the great caves of the world are in limestone rocks, of comparatively recent date. In the primary formations, these rocks being of limited extent, the caves, though numerous, are small. They are produced by the action of the water, which, running in little streams through the strata, and carrying with it carbonic acid gas (by which limestone is rendered soluble), particles of the rock are taken up and removed. Thus the rock is hollowed out more rapidly than others of a softer nature are excavated by any mechanical action; and the work goes silently and steadily on through long geological periods, until subterranean passages of wonderful beauty and extent are formed. In Sweden and Norway the granite presents caves of extraordinary size; that of Marienstadt, which has been only partially explored, is most prominent. In the neighborhood of Quito caverns are found in modern porphyry, and in the of Fra e in

his steps. In connection with the served, and has attracted the attention of men. A blast of cold air from the opening, so strong as to extinguish a candle. The current without is higher than the current of air sets out, and in the case the current is reversed, the prevailing current is outgoing to air carried into the cave and set free as this course. On this principle is called the *ventilator*. It is for furnishing poses. (See *Blow* Murchison, in Russia, where it is which is destitute of ice in the tially filled with it during the erns in various parts of the world which is found incrustated is detached with picks. In Kentucky; this caves a large number in the United

all were of extinct species. It is supposed that the Kirkdale cave was for many a den inhabited by hyenas, some great on at last destroying the whole race.

Bones have sometimes been found in receptacles, but this may be explained by common practice of mankind in all ages to bury their dead in such repositories, and by that very many of these caverns, as stated above, have been occupied as by ancient and barbarous nations.—

The most known cave in the world is the Mammoth cave in Kentucky. It is situated in Madison co., near Green river, 180 m. S. S. Lexington, on the road to Nashville. According to the statements of explorers, it has penetrated to the distance of 10 m., but these are probably exaggerated, as the windings of the cave are so tortuous, and the progress of travellers so much obstructed, and naturally very slow, that they may be easily deceived in this respect. Stalactites of gigantic and fantastic form are seen here, though none so brilliant and beautiful as adorn the interiors of many other caves. Nitre abounds. The river navigable by boats affords a novel mode for exploring these subterranean recesses.

Few forms of life are found within the cave. Bats and rats are abundant, and there are several species of insects. Two varieties of fish only have been observed: one of these is an eyeless fish; the other, though with eyes, is nearly blind. After the Mammoth cave, that is worthy of notice in the United States, is the cave named for its discoverer. It is situated in the co. of Augusta, near Port Republic, N. E. of Staunton, Va. Though inferior in size to the Mammoth cave, being but 2,500 feet in length, its rare beauty has given to it an almost equal celebrity. Its spacious apartments, extending to the distance of  $\frac{1}{2}$  m., adorned with their stalactites, are said to equal the enchantments described in eastern story. A cave has recently been discovered in Marion co., which promises to rival all others in size and beauty. It is known by the name of Big Saltpetre cave. Large chambers and galleries succeed each other; their height varying from 100 to 80 feet. The dropping water has formed the most beautiful stalactites, and the cave is decorated with groups of spar in a variety of figures. A number of caves have been described in New York. The most interesting of these is Ball's cave at Schoharie. It has been explored about  $\frac{3}{4}$  of a mile. Stalactites and stalagmites have been found in it of purest white. It contains 2 lakes, the surface of the one 10 feet above the level of the other.

CAVEAT (Lat. *cavere*, to beware), a formal warning or caution given by a party in interest, a court, judge, or public officer against the performance of certain acts, such as permitting a bill to be proved, granting letters of adaptation, or patents for inventions, or for the same. Its object and effect are to stay the

proceedings, in order to allow an interested party an opportunity to contest the application about to be made.

CAVEDONE, JACOPO, an Italian painter, born in Sassuolo, in the duchy of Modena, in 1577, died in Bologna in 1660. He was a pupil of Annibale Carracci. His best works are the "St. Alo," in the church of the Mendicanti at Bologna, the "Adoration of the Magi," the "Four Doctors," and the "Last Supper." Out of Italy he is frequently mistaken for Annibale Carracci.

CAVENDISH, HENRY, an English philosopher, born at Nice, Oct. 10, 1731 (during a visit of his mother, Lady Charles Cavendish), died in London, Feb. 24, 1810. He was a gentleman of great wealth, and a man of high attainments in chemistry and in general physics. He was the discoverer of the composition of water and of nitric acid, and proved that the electric spark will generate nitric acid from common air. He measured the density of the earth by direct comparison with balls of lead, and improved the modes of dividing astronomical instruments. His highest glory consists in his being the first chemical experimenter and discoverer in many important branches of that science. His writings may be all found in the "Philosophical Transactions" for 1766, '67, '71, '73, '76, '77, '88, '84, '85, '86, '88, '90, '92, '98, and 1809. Distinguished in science for the accuracy of his experiments, the largeness of his views, and the brilliancy of his discoveries, he was no less distinguished in private life for the excellence of his character, the regularity and simplicity of his habits, and his liberality toward other men of science.

CAVENDISH, or CANDISH, THOMAS, an English navigator of the 16th century. He was the son of a gentleman of good estate, residing at Trimley St. Martin in Suffolk, inherited his father's property, but becoming light in purse by living at court, he engaged in a predatory excursion against the Spanish American colonies, fitting out 8 vessels respectively of 120, 60, and 40 tons. This expedition started July 21, 1586, and entered the straits of Magellan Jan. 6, 1587. They were 88 days in clearing the straits, spending some time in examining the coast. On the Pacific ocean shore they burnt Payta, Acapulco, and other towns, and finally captured the Spanish galleon, the St. Anna, a vessel of 700 tons, loaded with a valuable cargo, and 122,000 Spanish dollars. Satisfied with this golden success, Cavendish started from California, crossed the Pacific to the Ladrone islands, through the Indian archipelago and straits of Java, around the cape of Good Hope, reaching England Sept. 9, 1588. In Aug. 1591 he started again, but he experienced bad weather and sickness, his crew grew mutinous, and he died either on the coast of South America, or on his way home, in 1593.

CAVERY, or CAUVERY (anc. *Chaloris*), a river of southern India, rises in the British district of Coorg, among the Coorg hills, near the coast of

and the leather taken back on the heads of the crew.

CAVERYPAUK, or CAUVERYPAUK, a town of British India, in the presidency of Madras, district of N. Arcot, on the road from Madras to Arcot, lat.  $12^{\circ} 54'$  N., long.  $79^{\circ} 38'$  E. A victory was gained here by the British over the French and their allies in 1754. The town is a poor and meanly built place, but contains a tank 8 m. long and 8 m. broad, which is perhaps the finest work constructed for irrigation throughout southern India.

CAVI, a picturesque Italian town, on the slopes of the Monte di Mentorella, in the Pontifical States, 8 m. from Palestrina; pop. about 2,000. It was built by the Colonnas, who held it as early as the 11th century, and is memorable for a treaty of peace signed here in 1557 between the duke of Alva and the Caraffeschi. On the ancient road, which was probably the line of communication between Palestrina and Anagni, is the battle-field on which C. Aquilius Tuscus defeated the Hernici, 487 B. C.

CAVIANA, an island of Brazil, 35 m. long and 20 m. wide. It lies in the N. mouth of the Amazon, under the equator; is level, fertile, and well stocked with cattle. The small town

became known in public life in 1847 as one of the founders of and contributors to *Il Risorgimento*, a journal of liberal politics. Count Cavour superintended the politico-economical department of this paper, and gave it a strong bias in favor of free trade. He entered the Sardinian chamber of deputies in 1849, and took his seat among the members of the moderate opposition. On the death of Santa Rosa, minister of agriculture and commerce, these portfolios were conferred upon Count Cavour, to which in 1851 was added the department of the finances. In 1852 he succeeded the marquis d'Azeglio as president of the council, an office which he has filled ever since, with the exception of a short period of retirement in 1855. He obtained a European reputation by the course he took in opposing the pope and the ultramontanes at home, and in joining France, Great Britain, and Turkey against Russia. The manifesto of Sardinia on this occasion was drawn up and signed by Count Cavour (Jan. 10, 1855). In conjunction with the marquis Villamarina, he represented Sardinia in the peace conferences held at Paris in the spring of 1856. During the sittings of this conference, he took occasion to protest against the continued occupation of the pontifical states by foreign troops, and to represent the necessity of inducing the king of Naples to moderate his system of government. Not less famous did he become from the part he took in carrying through the Sardinian parliament the measure for suppressing convents and monasteries, and secularizing their estates, which drew down upon him, and all who participated in the enactment and execution of this statute, the major excommunication of the pope, and the hostility of a large portion of the Sardinian clergy and their supporters in parliament. Despite the warm opposition of many powerful interests which his reforming tendencies have offended, the ministry of Count Cavour has been sustained by the masses of the people. After the attempt upon the life of the emperor of the French (Jan. 14, 1858), Count Cavour acceded to the requests of the French minister of foreign affairs, and proposed and carried through the legislature an act in reference to political refugees and conspirators against the life of foreign sovereigns, which was denounced by the democratic members of the Sardinian chamber of deputies. The act conceded a special jury of 200, to be designated by the mayor and municipal council of the town in which the court of appeal is established, for the trial of conspirators against foreign potentates. On the various questions which have arisen between the contracting parties concerning the construction of the European treaty of peace of 1856, and concerning the settlement of the Danubian principalities, the ministry of Count Cavour have supported French views, and have uniformly set themselves in opposition to the policy of Austria. The admirers of Count Cavour claim that he is the first of living Ital-

ian statesmen, and that to him more than to any other individual are Sardinia and Italy indebted for the successful institution of parliamentary government, religious liberty, and an unshackled press on the south side of the Alps. In Aug. 1858, the Sardinian minister had an interview with the Prussian premier at Baden, which was supposed to augur well for the future understanding between the two countries, and in August he attended the fêtes at Cherbourg.

CAVY, a mammal of the order *rodentia*, family *hystriidae*, sub-family *caviina* (Waterhouse), and genera *dolichotis* and *cavia*. This sub-family is exclusively South American; the molar teeth are  $\frac{4}{1}:\frac{4}{1}$ , without roots, those of the upper jaw converging and nearly meeting in front, incisors short, 4 toes on the fore feet, and only 3 on the hind, and (what is exceptional in rodents) without clavicles; they do not use the fore feet to convey food to the mouth. The cavies have been generally associated with the agoutis, and classed under the section *subungulata* of Illiger, erroneously in the opinion of Mr. Waterhouse, though the two groups approach each other in many respects, as in having the same number of toes, and in being almost or entirely destitute of a tail. In some members of the sub-family, and probably in all, the fauces, or entrance to the throat, form a funnel-shaped cavity, opening backward into the pharynx by a small aperture capable of admitting only very finely chewed food; by the action of the muscles this conical cavity is made to pass over the epiglottis, preventing the entrance of the food into the windpipe; the stomach is simple, but the cæcum is large and complicated. The molar teeth of the upper jaw have the entering fold of enamel on the inner side, while in the lower it is on the outer side; the palatic portion of the skull in front of them is much contracted, and between them triangular, the posterior emargination being very deep, and exposing the anterior sphenoid bone; in the lower jaw a well-marked ridge extends along the outer side from the 1st molar, at first horizontally backward, but afterward curving upward to the condyloid portion, distinguishing them from all other rodents; the condyle is but little elevated above the crowns of the molars, and the coronoid process is extremely small, in this and other particulars resembling the tailless hares (*lagomys*). The genus *dolichotis* (Desm.) is characterized by long limbs; ears half as long as the head, pointed, broad at the base; tail very short, and curved upward; metatarsus clothed with hairs anteriorly, posteriorly with the heel naked; molars small, the 3 front upper and the 3 posterior lower divided by folds of enamel into 2 equal lobes, the last upper and the front lower being 3-lobed. The long legs, large ears, and distinct tail distinguish this from the genus *cavia*, of which the Guinea pig is a well-known example. The cavies approach the hares in their comparatively short incisor

dry and tasteless. It has been generally mistaken by travellers for a hare, which it resembles in its legs, ears, and tail; the head is large, terminating in a blunt muzzle clothed with hairs; the upper lip is slightly notched; the mustaches are very long and black. The genus *cavia* (Klein) is characterized by short limbs and ears, by feet naked beneath, by molars nearly of equal size, each with 2 principal lobes. The genus presents 2 modifications of the molars: in one, the lobes are nearly equal, and the hinder lobe of the upper series has no distinct indenting fold of enamel; for this F. Cuvier has instituted the genus *cerodon*, which Waterhouse retains as a sub-genus; in the other (containing the Guinea pig), the hinder lobe is the larger, and in the upper series has a deep indenting fold of enamel on the outer side, and the corresponding half of the lower molar with a deep fold on the inner side. The following species belong to the sub-genus *cerodon*; those of *cavia* proper will be described under GUINEA PIG. The rock cavy (*C. rupestris*, Pr. Max.) inhabits the rocky districts of the interior of Brazil, in the higher parts of the river courses. The nails are short, obtuse, and projecting from large

ulation of 108,796, of whom 49,975 are distributed among the cantonments. It is poorly built, and has but one mosque of any pretension to elegance, but since its selection as a station for troops in 1777 it has acquired great commercial as well as military importance. It manufactures saddlery, harness, gloves, and jewelry; its shops are well supplied, its wharves are crowded with vessels, and its streets present a bustling and animated appearance. The race-course, the fashionable drive and promenade, and the best buildings, among which are an elegant theatre, handsome assembly rooms, and club rooms, are all within the cantonments, which stretch for 5 or 6 miles up the river, and are about  $\frac{1}{2}$  mile wide. Here are the barracks and many hundred bungalows, the latter built on the high banks of the Ganges, embosomed in fragrant groves and gardens, surrounded with every variety of eastern fruit, and often luxuriously furnished. The lines have accommodations for about 7,000 troops. The civilians, whose offices are in the native town, usually reside in the suburbs. —While the flames of rebellion were raging throughout Bengal in 1857, the military force at Cawnpore, commanded by Gen. Sir Hugh Wheeler, consisted of 3,800 men, of whom about 200 were Europeans. In June, symptoms of revolt induced Gen. Wheeler to throw up an intrenchment on the parade ground, enclosing 2 barrack hospitals and a few other buildings, into which he withdrew with 5 or 6 guns and about 900 Europeans, of whom  $\frac{1}{3}$  were women, children, and other non-combatants. On the 5th the expected rising took place. The native regiments marched off, taking with them horses, arms, and ammunition, and setting fire to the bungalows on their way. They placed themselves under the leadership of the rajah of Bittoor, commonly known as the Nena Sahib, seized 35 boat loads of shot and shell on the canal, and the next day appeared before the intrenchment. The siege lasted until the 27th, when the Europeans, now reduced to less than half their original number, suffering from pestilence and famine, their ammunition exhausted, and their weak ramparts half demolished, surrendered on promise of a safe passage to Allahabad. But no sooner had they embarked on the Ganges than they were fired upon from a masked battery. Many were killed in the boats; 3 or 4 made their escape, and the rest were captured and brought to land. The men were then put to death; the women and children were kept alive until July 15, when the Nena, hearing of Gen. Havelock's rapid advance toward Cawnpore, caused them to be massacred, and had their bodies thrown into a well. After defeating, in 3 obstinate battles, a strong native force sent out to oppose his march, Havelock entered the city July 17, while the Nena retreated to Bittoor. In November a monument to the memory of the victims of the Cawnpore massacre was erected on the spot by a detachment of the 32d (British) regiment.

CAWOOR, or CAWUR, a Malay town and district on the S. W. coast of the island of Sumatra. The town or village, situated at the mouth of an inconsiderable stream, in lat.  $5^{\circ} 5' N.$ , is a place of no note; it is composed of a few bamboo constructed dwellings, and has about 1,500 inhabitants. The district in the vicinity of the town is remarkable for its extensive forests of gutta percha and gutta taban trees, and for the abundance of tigers which infest these forests. Mr. Engel, a Dutch agent, for many years stationed at different points on the coast of the Bencoolen residency, in which this district is included, reported in 1853 that he traversed, in company with an armed body of Malays, different portions of this district, passing through one stretch of forest 11 miles in length, composed wholly of the 2 gum trees mentioned. He was of opinion that gutta percha could be extracted and prepared for shipment at Cawoor at a cost of 12 Dutch doits per pound, or  $2\frac{1}{2}$  cents U. S. currency. At the same time he records many desperate encounters with tigers; the encampment of the party was frequently attacked; the fires by which it was surrounded were overleaped by the terrible beasts, who sprang upon tents or the roofs of huts; and though many were shot and speared, several also carried off a human prey. The town of Cawoor is oftentimes thrown into a state of general alarm by a descent of tigers into its streets, even in daylight. The superstitious notions of the Malays prevent them from attempting any destruction of tigers, other than what may be effected in resisting an immediate attack; and unless a civilized government devises some efficient plan for the extermination of these powerful and ferocious beasts, the many rich products of the S. W. coast of Sumatra must continue to lie waste in its forests. Pepper and coffee have been advantageously cultivated in portions of this district.

CAXAMARCA, or CAJAMARCA, one of the 65 provinces into which the 11 departments of Peru are subdivided, in the valley of the upper Marañon, or Amazon; pop. of the province about 50,000, and of Caxamarca, its capital, 7,000. The city stands on the E. declivity of the W. Andes in a rich silver mining district, 75 m. from Truxillo. It contains several handsome churches, and flourishing manufactories of woollens and cutlery. The inhabitants are considered the best workmen in silver and iron in Peru. An extensive trade between the inland provinces and Lambeyeque and Truxillo is carried on through this town. Woollen fabrics form the chief exports, and European manufactures, sugar, brandy, wine, iron, steel, and other articles are imported in return. In the vicinity are the baths of the Incas, and a volcanic lake, into which, according to tradition, were cast the throne and regalia of the Peruvian monarchs, the last of whom, Atahualpa, perished here by the hands of Pizarro.

CAXATAMBO, or CAJATAMBO, a town of Peru, and capital of a province of the same

and Philip, duke of Burgundy, or if they thought it better, to make a new one. When the English princess, Margaret of York, married Charles, duke of Burgundy, she took Caxton into her household. While in her service, he translated from the French into English Raoul le Fèvre's *Recueil des histoires de Troye*, a work which he commenced at Bruges in 1468, and finished at Cologne in 1471. Having been long absent from his native country, he needed the assistance of his mistress to correct his English. From the prologues and epilogues of this work it appears that he was acquainted with the art of printing, and from the character of his types it is evident that he had learned the art in the Low Countries. The first 3 printed works of Caxton were the original of Raoul's "History," the oration of John Russell on Charles, duke of Burgundy, being created a knight of the garter, and the translation of Raoul, the last completed in 1471. There is no certain evidence of the exact period of Caxton's return to England; the usual supposition dates it in 1474; it is beyond doubt, however, that in 1477 he had taken up his quarters in the vicinity of Westminster Abbey, London. His printing office was in the Almonry, as appears from an old

and its geographical position render it one of the mountains of the world.

CAYCOS. See CAICOA.

CAYENNE, the name of a town in French Guiana, and a town in French Guiana. The island is separated from the continent by the rivers Cayenne and Oyapock, and which both these rivers are united in circuit, and is simply an archipelago over the level of the sea. Its name, it is said, is derived from the hamlets or villages of log cabins. The population of Cayenne is about 15,000. It is a tolerably large town, with neighboring hills on the north, and the various trees of Cayenne mentioned the caoutchouc, which is gathered there by Frisman. It is the capital of French Guiana, a penal settlement, is situated at the extremity of the island, and on the river. Pop. about 15,000. Since 1854 many political prisoners have been sent to Cayenne and

the town. The harbor, the entrance is protected by a fort commanding the bay. The bay is shallow, but otherwise good and adapted for merchantmen of moderate size. There are 2 quays for loading and unloading. The bay is head at the mouth of the river, though not the best on the coast. The average imports and exports during 5 years to 1855, was collectively \$900,000 per year. In 1856 the value of the imports was \$1,000,000 and of the exports \$820,000, total \$1,820,000, showing an increase of \$200,000 over the preceding years. The chief exports are the famous Cayenne pepper, cloves, nutmegs and tafia, coffee, cotton, and other imports, of wines, liquors, potatoes, machines, jewelry, cheese, butter, and dried meat, &c. The following table shows the list of the penal colonies of Cayenne and of their population in Jan. 1857:

	Free persons.	Transported.
Salut .....	214	1,176
Mère .....	83	119
Hill ( <i>Montagne d'Argent</i> )	103	145
Large's .....	26	150
St. Pierre .....	145	676
St. Augustin .....	77	376
Philippe .....	21	25
St. Julien .....	80	274
St. Louis .....	10	416
	763	3,857

In the spring of 1857, an accession of 560 transported convicts was received, bringing the total of transported convicts to about 4,000. A steamer and a galley sail monthly between Cayenne and the neighboring places of imprisonment. The island is called to distinguish it from the adjacent low entirely deserted, island Le Père, and is as the least unhealthy place on the coast; nevertheless, the climate kills a number of persons; among the recent victims 2 missionaries, Father Herviant, who died at Cayenne after a residence of 6 months at June 12, 1853, and Father Boulougue, died on the island itself, Sept. 26, 1856. The climate is that of the island of St. Pierre where a new penal colony was settled for blacks in April, 1853. The majority of the convicts who have since been sent there are from Martinique and Guadeloupe. Among the white convicts who arrived there in 1853, nearly half of them died before they could voluntarily starve themselves to death, and a third drowned. The convicts are composed of thieves, forgers, incendiaries, and murderers. The colony most fatal to health on the coast is Silver Hill, or *Montagne d'Argent*, situated at the mouth of the Oyapok, 25 leagues S. E. of Cayenne. Since the establishment of this colony the annual average of mortality was 40 per cent. In the neighboring marshes, the deposit of water, a rainy season of 8 or 9 months, added with extreme tropical heat, all conspire to produce here the most deadly climate. The most recently founded colonies are St. Augustin and Ste. Marie, in the early spring of 1855, and at a subsequent period St.

Philippe, all 3 on the right bank of the Oyapok river. The yellow fever has made terrible ravages in St. Augustin and in Ste. Marie: 1,150 persons were prostrated by the disease in 1856, and the missionaries sent thither died one after another. In 1857 appeared in Paris, *Mission de Cayenne et de la Guyane Française*, which is the first instalment of a more extensive work to be published, under the title, *Voyages et travaux des missionnaires de la compagnie de Jésus publiés par les pères de la même compagnie, pour servir de complément aux lettres édifiantes*.

**CAYENNE PEPPER.** See CAPSICUM.  
**CAYES, LES CAYES, or AUX CAYES,** a seaport town on the S. coast of Hayti; pop. 10,000. It is one of the most prosperous towns on the island, and contains several British commercial houses. An extensive smuggling trade is carried on between it and Jamaica. In the neighborhood of the town are upward of 80 rum distilleries. Les Cayes is the centre of trade of the Hautes Vaches, which lies opposite, and of the adjacent mountains. The climate, although unhealthy, is favorable to production. Its principal articles of trade are sugar, indigo, coffee, cotton, and rum.

**CAYLEY, ARTHUR,** an English mathematician, born at Richmond near London, Aug. 16, 1821, was educated at Trinity college, Cambridge, where he carried off the highest honors. He is one of the editors of the "Quarterly Mathematical Journal," and has contributed many papers to scientific periodicals, home and foreign.

**CAYLEY, SIR GEORGE,** a skilful and public-spirited Englishman, born at Brompton, Yorkshire, 1778, died Dec. 15, 1857. His genius first displayed itself in the analysis of the mechanical properties of air under chemical and physical action. His papers on the subject gave rise to many experiments on the navigation of balloons at home and abroad. His experiments on the steam engine led to his invention of the air engine. His discoveries in optics were followed by the invention of an instrument for testing the purity of water by the abstraction of light. He was also the inventor of an ingenious arrangement for obtaining and applying electric power to machinery. He was one of the original promoters of the polytechnic institution at London. Toward the end of the last century he applied to his extensive estates in Yorkshire a new system of arterial drainage. He was also the father of the cottage allotment system. As a politician, he took a prominent part in the election of liberal members of parliament, and the return of Mr. Brougham was chiefly due to his sympathy with the reform bill. Upon the passing of that bill he was himself chosen as member for Scarborough, but on account of his advanced age he soon retired.

**CAYLUS, ANNE OLAUDE PHILIPPE DE FERNEX,** count, a French archaeologist, born in Paris, Oct. 31, 1692, died Sept. 5, 1765. He early entered the military service, and distinguished

are Joloffs and Mohammedana. Capital, Macaye.

CAYUGA, a county of New York, a little W. from the centre of the state, bounded N. by Lake Ontario, W. by Cayuga lake, touching Skaneateles lake on the E., and traversed by the Seneca river and other smaller streams, which furnish abundant water power. Owasco lake, a beautiful body of water 10 m. long, lies in its centre. The county has an area of about 752 sq. m., with an undulating surface and fertile soil. Salt, gypsum, and limestone are found here in abundance. Wheat, Indian corn, oats, and hay are the staples. In 1855 this county produced 868,543 bushels of corn, 221,156 of wheat, 956,636 of oats, 57,782 tons of hay, and 1,957,183 lbs. of butter. There were 80 grist mills, 2 carpet factories, 2 cotton factories, 8 woollen factories, 18 tanneries, and 10 iron foundries. It contained 100 churches and 8 newspaper establishments. Pop. 53,571. Capital, Auburn.

CAYUGA LAKE, in the W. central part of New York, separates Cayuga from Seneca co., and extends S. into Tompkins co. It is about 38 m. l ; and from 1 to 3½ m. wide. It is ule in all p a, but for about 6 m. fr

it is well known ti the a large portion across the Afr ritory to but the descent into the vi leads to a region of of luxuriant trees. rivers numerous; the most or the Luviri, the Zamb abn The cli te is unhe y. with l V: probably The c products are nanas, and sugar-cane. plants, and us of the people session of of the Cuzco. a few goats. ad as well as territory sleep the night. monopolizes the trade, and derives his mainly from his copper mines and salt. Various expeditions have been set on by the Portuguese since the end of the last century into the territories of the Cazembe, and information gained of the country is derived through those channels. The last Portuguese book on the subject appeared in Lisbon and is entitled: *O Muata Cazembe e os seus reinos, Chevas, Muizas, Muembas, Lunas da Africa Austral*.

CAZENOVIA, a post village and township on the bank of the same name in Madison co., N. Y. pop. in 1855, 4,495. It is the seat of the conference seminary, an institution with 300 to 500 pupils.

CAZORLA, a Spanish town, in the province of Valencia, on the river Vega, on the slope of the Sierra de la Uti; pop. in 1852, 7,388. It is well known for the form of an amphitheatre, on the top of a mountain valley, and contains 2 squares, one of which is adorned with a fine fountain. It is defended by 2 old castles, the former of Moorish origin, and has numerous churches and schools, a spacious theatre, and in the gardens many delightful gardens and highly public walks. Cazorla was a military stronghold under the Romans, and figured conspicuously in the Moorish contests of the 13th century. In 1808 repeated attempts it was taken and burned by the French in 1811.

CAZOTTE, JACQUES, a French writer, born at Dijon, died Sept. 25, 1792. He is best known by a prose poem, *Olivier*, written in the style of Ariosto's poems. Soon after the publication of tales, full of wit and originality, which *Le diable amoureux* and *Le lord Olivier*, added to his fame. He was endowed with such facility and power of imitation that in one night he wrote a sequel to his first poem, *La guerre civile de Genève*, the effect was the imitation that no one could add to be Voltaire's own. Standing the apparent mirthfulness of his position, Cazotte, in his later years, became one of the most fervent adepts of the doctrine of Illuminism and Martinism. Being a royalist, he was arrested during the revolution, and escaped death at first through the intercession and entreaties of his daughter, but was rearrested and finally executed.

CAZENOVIA, ZACHARIA BEN MOHAMMED BEN CAZENOVIA, an Arabian naturalist, born at Cazoviyah of Persia, in the year of the Hegira (D. 1212), died in 682 of the Hegira (1283). His most important work, entitled "Wonders of Nature and the Peculiarities of Creation," contains an introduction, in which he discusses the nature and classifies the beings according to the principles of the Aristotelian philosophy; a 1st part, in which he treats of themes like the sun, moon, planets, and genii; and a 2d part, filled with observations and speculation as to earthly phenomena—meteors, winds, climates, rivers, and the formation of mountains. The

cause of earthquakes; the description of minerals, plants, and animals; and a particular account of man in an anatomical, intellectual, and moral point of view.

CEAN-BERMUDEZ, JUAN AGUSTIN, a Spanish archaeologist, born Sept. 17, 1749, at Gijón, in Asturias, died in Madrid, Dec. 3, 1829. He devoted himself early to the study of the fine arts, into which he was initiated by Raphael Mengs. After holding a public office at Madrid, he retired to Seville, where he founded an academy of fine arts, and occupied himself with the study of their history. He was elected a member of the royal academies of history and fine arts at Madrid, and published several valuable works connected with his favorite pursuits. His most important book, entitled *Sumario de las antigüedades romanas que hayen España*, appeared posthumously in 1832.

CEARA, one of the N. E. provinces of Brazil, bounded N. and N. E. by the Atlantic ocean, E. and S. E. by the province of Rio Grande do Norte, S. by Parahiba, and W. by Piauí; area in 1858, 42,600 sq. m.; pop. 210,000—the latter estimated in 1856 at 385,800. The province sends 4 senators and 8 deputies to the Brazilian parliament. The capital is Fortaleza. The climate is hot and dry; the soil sandy and barren along the coast, but more fertile toward the mountains. In the lower districts grain and manioc are cultivated, and along the rivers cotton. The most fertile and populous districts are about the upper branches of the Rio Jaguaribe, the most important river of the province. The province is celebrated for its cattle, and for its fine forests. The chief exports are cotton, hides, and dyewoods. The other products are sugar, tobacco, pineapples, amethyst, alum, and a small quantity of gold. Agriculture and the rearing of cattle form the principal occupations of the inhabitants.

CEBES, a Greek philosopher of the 5th century B. C. He was one of the pupils, friends, and disciples of Socrates, and is introduced by Plato as one of the personages conversing in the dialogue, so famous in all ages under the name of "Phædo." He was a native of Thebes, in Bœotia, and is, in addition to the splendid examples of Pindar, Epaminondas, Pelopidas, and Plutarch, an evidence against the truth of the proverb of *Bœotum crasse jurare adre natum*, which has assigned to the natives of that state the unenvied birthright of natural stupidity. This Theban Cebes, however, composed 3 dialogues called *Hedonism* or the seventh, *Phrynichus*, and *Pinax*, the tablet or picture. Of these, the last alone has come down to posterity. It is a moral sketch or picture of human life, equally pure in its Greek style and its moral teachings. The authorship of this work has been questioned by modern critics, some of whom ascribe it to a later Cebes, of Oxyzia, while the foremost Greek scholars all maintain that it was the production of Cebes, the learned Theban. No work of antiquity has had a wider circulation than the

"Picture" of Cebes. It has been translated into almost all the modern languages, even into Arabic. The best editions are those of Schweighäuser (Strasbourg, 1806), and of Coraes, in his edition of Epictetus (Paris, 1826).

CEBU, or ZEBU, the name of a province, island, and town of the Philippine archipelago. The island lies between lat.  $10^{\circ} 30'$  and  $11^{\circ}$  N., 87 m. long and 16 m. broad; area 1,211 sq. m.; pop. 272,000, and 220 to the sq. m. This island was the first land of the Philippines with which Magellan held intercourse; he landed upon it April 7, 1521; and it is noted in the archipelago as being the first upon which Christianity was preached. However, the rapid conversion which then took place, the baptism of the king and queen of Cebu and all their court, was mainly effected by the persuasions and threats of the zealous circumnavigator, and after his violent death a speedy and general apostasy ensued. It was not till the arrival of Don Miguel de Legaspi, the first Spanish governor of the Philippines, 44 years after the death of Magellan, that the thorough conversion of the inhabitants began. The general adoption of Christianity by the people of this considerable island, and their hearty abandonment of a horribly degrading idolatrous worship, is attributed mainly to the zeal and energy of Andrea de Urdaneta, a humble priest of Seville, who ranks with Xavier as an indefatigable, fearless, and pure-hearted missionary of the cross, and who accomplished far more than Legaspi and his army in effecting the conquest of the Philippines. The progress of the island in population and agricultural development has been rapid; its population in 1735 was only 28,320, in 1799 it had more than trebled the previous census, and now there are in Cebu 12 times the number of inhabitants that there were a century and a half ago. The surface of the island is very uneven, and the soil is thin and stony, and except in a few fertile valleys generally unfavorable to cultivation; but the docile and industrious Cebuans produce an ample subsistence for themselves of rice and other vegetable productions, and export some tobacco, hemp, and cocoa. The climate is very healthy, and instances of natives exceeding the age of 100 years are quite common. An enumeration of 32 Cebuan centenarians is given in Spanish statistical reports, one of whom had attained to the advanced age of 137 years. A low range of mountains forms a water-shed the whole length of the island; the streams that descend from the slopes on either side are all too inconsiderable in depth and too full of shoals to be available for any purposes of navigation; but gold has recently been found in large quantities in all these streams, and the mountains are said to be rich in fossil coal. Exports of both these minerals are beginning to increase the importance of the commercial port of the same name, situated on the W. coast, in lat.  $10^{\circ} 18'$  N., and opposite to the small island of Mactan, which is noted as the place where Magellan was

slain. The population of the town is 7,000. It is the seat of a bishopric, and civil and military administration of the ince, which includes, beside the the neighboring islands, Bohol, Minto, Panglao, Fuego, Polo, Davao, and considerable islets. The population of the ince in 1850 was 889,078, of which nearly third are on the small island of Bohol. The op of Cebu has jurisdiction over 13 of provinces of the Spanish Philippines. The first Christian character implanted by among the first converts of Cebu has been served by their descendants, and given an ecclesiastical establishment a mark of distinction in the archipelago. The people are of the Bisaya nation, and there are no or wild races in the province. Among the descendants of Europeans and men, are the chief merchants of the town, although they are the most opulent inhabitants yet are regarded unfavorably by a pure race, as well as Europeans, and are compelled to occupy a quarter of the town themselves. The prejudice against mixed blood is probably stronger in the Philippines than in any other portion of the eastern hemisphere.

CECIL, a N. E. county of about 300 sq. m., bordering on Maryland and Delaware, and situated at the head of Chesapeake bay, which forms its S. boundary. Pop. in 1850, 18,939, of whom 8 slaves. Its W. border is washed by the Potomac, and the Susquehanna and Sassafras river bounds it on the E. The surface is slightly uneven, and fertile and carefully improved. The productions in 1850 were 410,060 bushels of wheat, 168,112 of wheat, 208,380 of oats, 10,000 tons of hay. Butter, cattle, and swine are other principal articles of export. There are 10 factories, mills, furnaces. Port Deposit are immense granite quarries. The country also contains gneiss, slate, chrome, and sulphate of magnesia. It is intersected by several railroads leading from Philadelphia to Baltimore. Organized capital, Elkton.

CECIL, ROBERT, earl of Salisbury, an English statesman, son of Lord Burleigh, by his 2d wife, born about the middle of the 16th century, died at Marlborough, 1612. He was of weakly constitution, deformed in person, but gifted with great acuteness and energy. On his election as member for Westminster, his talents attracted the notice of Queen Elizabeth, who attached him to the French mission, and subsequently appointed him assistant secretary of state. The earl of Essex was the queen's favorite. His influence with the Cecils (father and son) came into collision; consequently a rivalry between them, which continued, open and secret, until Essex perished on the block in 1596. Secretary Walsingham died. Cecil was named the office for a nominee of the queen.

while Burleigh requested it for his son Robert. The queen, unwilling to offend her favorite, left the appointment open, and it was not till 1596 that Cecil was installed as principal secretary of state. While Essex was absent on the 2d Spanish expedition, Cecil contrived to procure for himself the chancellorship of the duchy of Lancaster, which the earl had requested for a friend. That quarrel was, however, made up, and Cecil, being sent to France, much against his will, to negotiate a peace between Henry IV. and the Spaniards, deemed it an effectual way of tying his rival's hands to confide the secretaryship to him during his own absence. Essex discharged the trust honorably. Cecil's first act on his return was to thwart Essex in his attempt to obtain the deputyship of Ireland for his friend Sir George Carew, an incident which brought about the celebrated quarrel in which Elizabeth boxed her favorite's ears and invited him to "go to the devil." Essex's fall was rapid, and Secretary Cecil was soon relieved from his rivalry. He is accused of having in like manner sacrificed Sir Walter Raleigh, while professing to be his friend. Cautiously, but surely, he supplanted the influence of all others around the throne, and centred the whole power of the court in himself. On the death of his father he was made premier. Elizabeth placed every confidence in his administration. He was at all times ready, in appearance, to sacrifice his own views to the "divine judgment of his sovereign." Yet in reality he endeavored, with success, both in Elizabeth's reign and her successor's, to restrain the power of the crown. Having secretly favored the interests of James I., he was rewarded by that sovereign, on his accession, by being continued in office, and by being created, in 1603, baron of Essenden; in 1604, Viscount Cranbourn; and in 1605, earl of Salisbury. In 1608 he succeeded Dorset as lord high treasurer, notwithstanding the exertions of his new rival, but former friend, Henry Howard, earl of Northampton, to obtain the office. When the gunpowder plot was found to be really no fiction, he entered actively into the detection of the conspirators. A work of his is extant, entitled "A Treatise against Papists." James had the highest opinion of his sagacity in discovering plots, and called him on that account by the familiar appellation of "my little beagle." He could not be brought, however, to assent to James's project for the incorporation of the 2 kingdoms. This backwardness caused the suspicious monarch to fear that he was at heart a Puritan. In all other matters the king followed his lead, asking nothing in return but money to carry on his extravagant expenditure. Thus, the whole cares of the government were thrown on his shoulders. James had no order in his expenditure. The ordinary revenues being insufficient to meet his wants, imposts were laid on articles of commerce by proclamation. The country denied the constitutionality of this proceeding, but the

court of exchequer decided in favor of the king. Cecil interposed between the king and the people. He asked, in conference of the 2 houses of parliament, that an immediate subsidy should be voted to liquidate the royal debt, and that an addition of £200,000 be made to the annual income, to prevent the recurrence of a similar exercise of the king's prerogative. Parliament retorted on the king by a demand for numerous reforms. After protracted conferences, both houses adjourned without granting the required supplies. The failure of his proposition was a source of bitter mortification to the treasurer. His health sunk under a complication of disorders. Having tried the mineral waters of Bath without benefit, he set out for London, but died on the way. Cecil was a man of consummate skill, sagacious and honest in administration, far-seeing, fertile in expedients, and unscrupulous in using them. His administration imparted to the last days of Elizabeth the brightness that Burleigh's talents shed on the earlier part of her reign. That the opening of James's administration was less brilliant than the preceding was owing less to the minister than to the pusillanimity of his master. Lord Hailes published "Secret Correspondence of Sir Robert Cecil with James VI. of Scotland," 12mo. 1766.

CECIL, WILLIAM. See BURLEIGH, LORD.

CECILIA, SAINT, a saint of the Roman Catholic church, whose anniversary is celebrated Nov. 22. She was a Roman lady of high descent, born about the middle of the 2d or the commencement of the 3d century. Compelled by her parents to marry Valerian, a noble youth of Rome, although she had at an early age made a vow to consecrate her life to religion, St. Cecilia was eventually doomed to suffer martyrdom; and her husband, her brother-in-law, and another Roman, whom she is believed to have converted, were supposed to have met with the same fate. St. Cecilia is the chosen patroness of musicians, and from her skill in singing, is especially regarded as the patroness of sacred music. Several churches were built in her honor at Rome. Beautiful pictures of the saint were executed by Raphael and other celebrated painters, and Father De Brailon of the Oratoire published in 1668 a work entitled, *La sépulture admirable de Sainte Cécile dans son église de Rome*.

CECROPS, first king of Attica, about 1550 B. C., is represented in the ancient legends as the civilizer of that country. He founded Cecropia, which at a later period formed the Acropolis of Athens, and several other places; divided Attica into 12 communities; taught its inhabitants morality and manners, marriage, and the worship of the gods; abolished bloody sacrifices, and introduced agriculture, navigation, ship-building, and the culture of the olive. According to some, he was of Pelasgian origin, while others say he was the leader of an Egyptian colony from Sais. He reigned 50 years. His merits were commemorated by a monument in

human found it difficult to procure cedar timber enough for the roof of a single church. The cedars of Lebanon have now dwindled to a few groves, the principal of which is a thick forest containing about 30 very large trees, 50 of middling size, and 300 smaller and young ones. It occupies a natural amphitheatre at the foot of the wildest of the gorges of Lebanon, and is regarded by the people as sacred. The largest of the trees have a diameter of 9 feet. This cedar is now extensively cultivated as an ornamental tree in Europe and America, one or two specimens of it giving variety and force to a dull front of round-headed trees.—The cedar of Goa is found wild in parts of India and in Japan, and has been naturalized in Portugal around Cintra. It is the handsomest tree of the genus *cupressus*, and distinguished by its abundance of long dichotomous pendent branchlets.—The Indian cedar is a large tree found wild on the mountains of Nepaul and Thibet, at a height of about 10,000 feet above the sea. Its timber possesses the qualities attributed by the ancients to the cedar of Lebanon, being compact, resinous, and fragrant. It is much used for building in India, has been introduced into England as an ornamental tree, and has been successfully

Colonny, south Africa, extending 57' to 32° 24' S., and nearly along of 19° E. They are of primitive with peaks from 1,600 to 5,000 feet level of the sea, covered with green trees. At heights of from 300 to above the valley are found many caves with well-executed drawings. An ash-colored quartzose sandstone nates in the higher parts, and marbles the lower. The valleys between are very fertile.

CEDAR SPRINGS, a post village, tanburg dist., S. C., is an old village and the seat of a state deaf and dumb school, a prosperous and well-conducted community originally established by the Rev. N.

CEFALU (anc. *Cephalædis*), a port town, at the foot of a rock, on the island of Sicily, capital of a district of the same name (which is divided into three in the province of Palermo, and 80 in that city; pop. 8,940). The town is a bishopric, and contains a fine cathedral and several other churches. The remains of a Punic edifice, a castle built by the Arabs, and several marble quarries, are in the town.

8 chapels, several schools, a theatre, and handsome public buildings.

CELAKOWSKY, FRANTISEK LADISLAW, a Bohemian poet and philologist, born at Strachow 7, 1799, died in Prague, Aug. 5, 1879, having learned German in his childhood. He entered the gymnasium of Budweis in 1814, studied subsequently at Pisek, Linz, and Vienna. He was destined for the pulpit, but religious impulses declined to adopt that career, and engaged in 1821 as instructor in German in his father's family, where he could at the same time pursue his literary occupations. He published a series of original and translated poems, remarkable at that period of transition from the old classical to the modern national style in the Cechic literature. In 1828 he became associate editor of the "Quarterly Review of Catholic Clergy," published by the conference at Prague, and in 1834 editor of the "Bohemian Gazette," and of the "Bee," a literary journal. He also commenced a series of lectures on the Cechic language and literature, at the university of Prague. He lost both his position as editor and that at the university, in consequence of a remark against the emperor. The favor of public opinion, however, and a comfortable situation as librarian of the library of the princess Kinsky, were in his favor. He was a friend of his liberalism. The Bohemian movement for the propagation of science elected him president in 1840. In 1842 he accepted a professorship of the Slavic language and literature, established by the king of Prussia for the benefit of his Polish subjects, at the university of Breslau. After the events of 1848, the Prussian government, which now sought support from the Cechic nationality, offered him a professorship at the university of Prague. He did not live long to officiate in this capacity, death having been accelerated by domestic troubles and mental suffering. Of his numerous works, the following are most remarkable: "Poems" (Prague, 1822, new edition, 1879); "Slavic National Songs" (8 vols., Prague, 1827-32); "Lithuanian National Songs" (Prague, 1827); a metrical translation of Walter Scott's "Lady of the Lake" (Prague, 1828); translation of Augustine's *De Civitate Dei*, 5 vols. (Prague, 1829-32); "Echo of Russian National Songs" (Prague, 1829); "Echo of Cechic National Songs" (Prague, 1840). One of his last works was the "Popular Philosophy of the Nations in their Proverbs" (Prague, 1840). After 1835 Celakowsky was engaged in comparative study of all the Slavic dialects, of which is given in part in his edition of Johann's Cechic dictionary. As a poet, he is distinguished by the grace and naïveté of his poems.

CELBRIDGE, a town of Ireland, in the county of Kildare, 15 m. W. from Dublin, on the east bank of the Liffey, which is here crossed by a handsome stone bridge; pop. in 1871, 674. Manufactories of straw hats and of linen wares are carried on here.

In the vicinity are Reeves castle, the seat of the earl of Leitrim, and Lyons castle, the seat of Lord Cloncurry. Swift's Vanessa resided for some time at Celbridge abbey, the residence of Mr. H. Grattan.

OELEBES, an island of the Malay archipelago, of singular conformation, representing in appearance 5 extensive peninsulas grouped around a small central body. The northern, or peninsula of Menado, intersected by the equator, about one degree from its junction at the bay of Palos with the central mainland, extends from this point nearly due E. to its extremity at Cape Polisan, 480 m.; the N. E., or peninsula of Balante, is 182 m. long; the S. E., or peninsula of Teboonkoo, is 170 m. long; the S. W., or Boni peninsula, 160 m.; and the W., or Mandar peninsula, is a short projection about  $\frac{1}{2}$  a degree in length. Celebes extends 800 m. from its N. E. extremity to its most southern point; it has an extent of sea-coast equal to all the Atlantic United States, or about 2,600 m.; and yet its area is but 68,500 sq. m., or about the extent of the state of Missouri. The 3 extensive gulfs, Gorontalo, Tomaiki, and Boni, which serve to form these peninsulas, are very shallow, especially Gorontalo or Tomini, which, though making an indentation of 240 m., yet has not sufficient depth of water to permit the entrance of the largest class of European vessels; and even those of the lightest burden have not been able to approach within 10 or 15 m. of its almost unknown coasts. But at the period of the first European intercourse with the island, 3 centuries ago, Portuguese frigates freely navigated this broad bay. There has been a sensible diminution in depth of the waters surrounding this island, and it is manifest that a gradual upheaval of this portion of the archipelago is in progress; and in the course of time, this and the neighboring island of Gilolo, which is also a group of peninsulas, will have their great bays filled up by *terra firma*, and will exhibit an unbroken outline like Borneo, which evidently at one time presented the same singular configuration as these two islands. Elevated mountain chains extend throughout the whole length of each peninsula of Celebes; but the peninsula of Menado alone is of volcanic origin, and it has 3 active volcanic peaks, about 5,000 ft. high, near the E. extremity. The highest peak of the island, Lompo Batang, 8,290 ft. high, is near the extremity of the S. peninsula. The surface of the central mainland and of portions of the S. W. and S. peninsulas, is mostly elevated table land, covered with excellent pasture grasses, upon which are found grazing great numbers of wild horses and buffaloes, as on the prairies of America. These natural pastures of Celebes are a peculiarity, not observed on any other island of the archipelago; but it has recently been found to be the case upon some of the Papuan islands, lying between the Malaysian and Polynesian formations. These extensive plains, which serve for hunting

in of islands said to abound in n of as *si labih*, "still more" the European intruders might see the same as they had found a group of islands. The Portuguese touched at the points of 2 peninsulas; they were different islands; and they named them as *ilhas Celleses*, soon being adopted by De Barros, Castañeda, and other Portuguese as become fixed in geography and name of the island. But such a name known to its inhabitants, who call it "Negri Bugis," or the Bugis, the advanced of the nations of Celebes, converted to Mohammedanism some time after the arrival of the Portuguese in the island. They disregarded the teachings of these missionaries, which were so strictly and faithfully observed by the neighboring Molucca islands. In the course of the Dutch with the island in 1607. In 1660 they expelled them from their possessions in the Macassar. The Dutch maintained their possession of Celebes for 2 centuries, till their evacuation by the British in 1810. But their possession of Celebes, along with those in the Moluccas, was restored to them in 1816. The Dutch Macassar a free port in 1846, Singapore; and Kema, in the Moluccas, in lat. 1° 22' N., and long. 125° E., declared a free port in 1849. In Roman antiquity, a regiment of *celeres* instituted by Romulus, composing men of the most illustrious families, were elected by the suffrages of the tribes, each of which furnished 10. It has been derived by some from the Greek *celeros*, first chief, but more probably was introduced in allusion to the rapidity with which they executed their orders. Their command was called the *tribune of the celeres*, and the highest officer in the army was held by Brutus when he drove the king from Rome. The *celeres* were, according to Niebuhr, to have been the patriarchs, so called because they could fight on horseback, and thus to have been the later *equites* or knights. *Apium graveolens*, Linn.), an important cultivated for salad. In its natural state, which it is found in ditches and swamps, it is rank, coarse, and even inedible; but by cultivation in gardens it becomes crisp, juicy, and of an agreeable flavor. The leaves, stems, and seeds are eaten, and the blanched stalks either used more usually as a salad. One of the most common, the *celeriaceae*, is raised only for the purpose of the leaves, which becomes a bulb. Celery requires a deep, rich, and well-drained soil. The seed is sown in a box, the plants are transferred to the garden when they are 2 or 3 inches high. At the height they are transferred for

blanching to trenches which are nearly 1 foot in depth. The plants are repeatedly earthed up till they have risen 2 feet or more above the natural surface. Celery is not blanched, but grows openly, exposed to the light.

CELESTINE, the name of 5 popes. I. ST. CELESTINE, whose anniversary is celebrated April 6, a Roman by birth, and related to the emperor Valentinian, was created cardinal deacon by Innocent I., and succeeded Pope Boniface, Nov. 8, 422. The heresy of Nestorius induced him to convoke the council of Ephesus in 431, at which 200 bishops were assembled, and which was presided over by his 8 legates. Celestine, the chief of the Pelagians, having retired into Britain, he sent missionaries there who, in the space of 2 years, brought back that country to the faith. Shortly after this he sent Palladius to Scotland, and St. Patrick to Ireland. Some epistles of this pope have been preserved, but those written to the bishops who had taken part in the election of Nestorius and to Eugenius have been lost. He died April 6, 432, and was buried in the cemetery of St. Priscilla, on the Via Salaria. II. GUIDO DI CASTELLO, was a disciple of Abelard, and was created cardinal priest by Honorius II., and made governor of Benevento by Innocent II., at whose death he was elected pope, Sept. 25, 1143. As soon as he had ascended the pontifical throne he received ambassadors from Louis VII., who came to supplicate peace, and also absolution from the ecclesiastical censures under which the kingdom had been laid by his predecessors. The pope granted their request in the presence of the nobles of Rome. Having occupied the pontifical see 5 months, he died March 9, 1144, and was buried in the church of St. John Lateran. Only 8 epistles of his are extant. III. GIACOINTE ORSINI, a Roman by birth, and descended from the illustrious family of that name. He was created cardinal by Honorius II., elected pope when past 80 years of age, March 30, 1191, and died Jan. 8, 1198. The day after his consecration he crowned the emperor Henry VI., and his empress Constance. After the coronation, the emperor restored to the pope the city of Tusculum, which the pope gave to the Roman citizens, who to avenge some former disputes destroyed it. He afterward excommunicated the emperor, because he kept in prison Richard Cœur de Lion. Among other noteworthy events of Celestine's pontificate was his confirmation of the Teutonic military order in 1192. IV. The son of John Castiglione, of Milan, and Cassandra Crivelli, the sister of Urban III. He was appointed canon and chancellor of his native city, and afterward became a monk in the monastery of Altacombe. Gregory IX., in 1227, created him cardinal, and sent him as legate into Tuscany, and after this to Lombardy and to Monte Casino, where he found the emperor Frederick II. preparing to send succors to the Holy Land. He was elected pope Sept. 20, 1241. Advanced in years, and with health much impaired by in-

his retirement, he refused to accept the dignity, though the cardinals and Charles II. king of Naples, and Andrew III. king of Hungary, urged him strongly to do so. He attempted to fly from his retreat, but was prevented by a vast concourse of people. At length he consented to accept the dignity, and proceeded to Perugia accompanied by the kings of Naples and Hungary, and was crowned Aug. 29. He made his public entrance into the city amid the applause of more than 200,000 people. In the city of Aquila he appointed 12 cardinals, 5 of whom were Italians and 7 French, and then went to Naples. He made 2 constitutions which provided for the cardinals entering into conclave on the election of a pope, thus renewing a constitution already made by Gregory X. in the council of Lyons; and also another respecting the pope resigning his office. After occupying the pontifical see during 5 months, he renounced the tiara, Dec. 18, 1294, on finding that he was but little acquainted with temporal matters, and still retained his unconquerable love for solitude. The see remained vacant 10 days, when Boniface VIII. was elected his successor. Celestine then retired again to his solitude at Maffella, to devote himself altogether to prayer and

rigor. It is remarkable that while celibacy was proscribed in Europe, it was the East. There celibates bore names, were raised to high offices, and styled eunuchs of the sun and heaven. With the progress of Greece and Rome, the celibate more common, and custom triumphed over laws. Thus often the men of letters, philosophers, athletes, gladiators, and some from taste and some from necessity renounced marriage. This was the case with the disciples of Pythagoras and Diogenes. Celibacy was early a peculiar privilege and duty of the priests. Among the Jews, those who were in the service of the temple were forbidden to marry, but under certain special circumstances. Among the Egyptians, the priests were bound to chastity. The gymnasts, Brahmins of India, and the hierophants of Athens, lived in celibacy. Among the Persians, the maidens among the Parthians, and the worship of the sun, and among the Romans, who submitted to guard the sacred fire, the custom of celibacy was common.

umph. Yet there was no law nor opinion or action on the subject, not till the 4th century that even clergy began generally to live in the council of the Spanish and African bishops at Elvira, in Spain, A. D. 805, ecclesiastics of the 3 first grades to conjugal intercourse under penalty. A motion to the same effect at the general council of Nice, in 451, it was rejected. Yet a tradition current about that time, that priests and monks should not marry, and this practice being once established naturally to the opinions that married men should not be admitted into holy orders, and that celibacy was a more honorable than marriage. In the Latin church the law of celibacy was most strictly observed at the close of the 4th century, and forbade conjugal intercourse to all without distinction, and this interdiction was maintained by the subsequent popes and emperors. Justinian declared the marriage of ecclesiastics illegitimate, and incapable of inheritance. The council of Tours, in 517, decreed that married monks and nuns incurred excommunication, and that their marriages were null. The Greek church opposed the law of the Latins, and has always recognized the marriages of priests and deacons in place before their consecration, and the bishops who are chosen from among them, are unmarried. In the Roman church the law of celibacy was frequently occupied with measures against violations of the law; and observance of the law was insisted upon under the pontificate of Gregory VII., who excommunicated every priest, and every layman who should officiate at a service celebrated by him. The law of celibacy was rejected as contrary to nature by Protestant ministers, and their thought at first of maintaining the law of monks, by reason of their vow, was abandoned. This innovation was brought up again in the Catholic church, although the emperor, the king of France, and many of the electors and princes were opposed to the marriage of priests, yet the council of Trent, which closed its sittings in 1563, decided finally to retain the discipline of celibacy. From that time the law was absolute in the Roman Catholic church. One who has been married cannot be admitted if his wife is living, unless a dispensation takes place between the parties by the pope. Those who have yet attained to the higher orders may renounce their benefices, and their orders, and be married; but even those with sub-deacons and the higher orders, such as the pope alone, notwithstanding the indissolubility of the character of priest, are permitted to retire from the priesthood, and subsequently to contract marriage. The simplest form of organic life, from

which all vegetable and most animal structures are built up. Since the improvement in the microscope within the last 25 years, and more especially since the researches of Schleiden in 1837, and of Schwann a little later, the attention of physiologists has been unceasingly directed to the minute elementary structure of living things. The observers last named have shown that a cell, containing within it another cell (the *nucleus*), the latter containing a granular body (the *nucleolus*), is the primary form which organic matter assumes when it becomes an organic structure; the bodies of many animals and plants are composed entirely of cells, and the tissues of the embryo, in the first instance, consist of nucleated cells, which are developed into the dissimilar textures of the adult animal. However great the difference may seem between the animal and the plant, when seen by the unassisted eye and in their perfect form, they gradually approach each other as we descend in the scale, and finally meet in a common structure, the simple individual cell; and, when reduced to this, no one can say to which of the two great kingdoms it belongs. The microscope has revealed the great fact of unity of plan in this elemental structure throughout the organic world. In former times the power of spontaneous motion and the presence of a stomach were considered the distinctive attributes of animals; but we now know that most of the lowest vegetables possess this power at some period of their lives, and by the same hair-like filaments, or *cilia*, by which the lower animals move; while the sponge and some *protozoa* have neither the power of motion nor a proper stomach. No chemical element can be considered as a characteristic of the animal as distinguished from the plant; and we have seen that the primary cells are absolutely indistinguishable from each other. In the cell, however, is to be found the distinction between plants and animals, viz., in its power of development, in its destiny: in the plant, the cell, however changed in form and contents, always retains the characters of a cell; but in the animal the cell usually undergoes a development into tissues, in which the cellular form completely disappears. In the developed animal of the lowest types, where the distinction is the most difficult, the elements of nutrition are eminently characteristic; the simplest *protozoa*, which seem to be only a mass of living jelly, must feed upon organic compounds derived from other living things which are taken into the interior of the body; while all plants derive their nourishment from the absorption of inorganic elements by the external surface, and evolve oxygen, by the decomposition of carbonic acid, under the influence of sun-light; so that the simplest members of the two kingdoms, which cannot be distinguished by any peculiarities of structure, are separated physiologically by the phenomena of nutrition. Though the vegetable and the animal cell do not differ except in their ultimate development, it will render the subject more intelligible to begin with

pression, the cell. 2. The universality of the application of this particle for the formation of organized parts, the tissues." The vegetable cell is a membranous vesicle containing a fluid. The cell wall is composed of two layers: an inner, called the "primordial utricle," first formed and the most essential to cell existence; it is thin and delicate, and of albuminous constitution; the outer layer is produced after the primordial utricle and its contents are enclosed, and takes no part in the formation of the cell; it is thick, strong, and principally composed of cellulose, a starch-like substance containing no nitrogen. The outer layer is merely protective, while the primordial utricle is engaged in the vital operations of the cell. The contents of the vegetable cell, more or less deeply colored, have been collectively called "endochrome," and consist of colorless protoplasm or organizable fluid containing albuminous matter, and in the interior a mere watery sap. The distinction between wall and contents cannot be made out in some of the lowest forms; sometimes the cell appears as a mass of endochrome, retaining its form by its own viscosity, the superficial layer gradually becoming consolidated, and the interior becoming more liquid: and this has been

usually contain an evident nucleus, which assumes a brownish yellow color by an iodine solution; the nucleus contains smaller cells, or in the lowest plants the single cells live distinct; others unite together in branched or star-shaped masses; others join in a regular series. In the vegetable kingdom the cells usually increase by division, each cell dividing with its half of the primitive contents, and the new cell secretes its own gelatinous envelope, and soon becomes free from the parent cell. Sometimes the subdivision is so fine that a series of cells is produced without a distinct envelope, hanging on to each other. As they grow, the cells of the higher forms are developed into special organs. General division in the lowest plants is effected by the union of a pair of cells, by a process termed conjugation, the membrane as well as the contents being completely fused; the result is a single mass, the primordial cell of a new generation, which possesses the remarkable properties of the vegetative cells, especially in the lower forms, where the power of motion is retained.

or green vegetable wax, the cause of an color of plants, and existing in the and young stems when not deprived of it is soluble in alcohol and ether, and a thin coating to the granules of the cell.

of water plants the circulation of contents of the cells may be easily going up one side and down the other, jumping into adjoining cells; the nucleus, a nucleolus, may be distinguished from

by its larger size and its greater transparency. Elongated cells unite in many plants in vessels containing milky secretions; these are the juices whose concretion produces galls and gutta serena. Fixed oils and as contents of cells, especially in the seeds, where they serve to nourish the embryo; among these are the cocoanut, castor, croton, linseed, rape, and others used in medicine and the arts. Cells also contain volatile oils, camphor, gums, wax, and they contain crystallized mineral substances, called raphides, usually salts of lime; erogen, a gritty substance found often in the core of pears, giving hardness to fruit-stones and nutshells, and constituting the dense white substance known as vegetable ivory. The stings of nettles, as of the nettle, are elongated cells containing an irritating liquid. The beautiful colors of flowers depend on coloring matters, dissolved in fluid, contained within the cells. All cells, then, are made up of a primitive membrane existing in the form of cells, each providing the young state with a nucleus or cytonucleoli, which by aggregation and division make up all their tissues; each cell has an independent existence, and secreting matter may be necessary for the perfection of the tissue of which it forms a part, or for the reproduction of its species.—In addition to what has been said before (in vol. i. pp. 522, title ANATOMY), it may be stated that the cell in its simplest form lives independently of other cells, and requires for its growth and maturity nothing but a proper nutriment and atmosphere. Like the vegetable cell, it originates from a reproductive germ or granule, prepared previously by another cell, which organizes nutrient particles in its neighborhood, and from them the cell wall and its contents, which are reproductive granules, the seeds of new cells to be set free by the rupture of the cell wall; unlike the vegetable cell, it cannot live in itself inorganic elements, but must be supplied with an

organizable nutrient fluid supplied to it, from which each cell selects the elements for the performance of its function. The cell has no cellulose wall, its contents are enclosed in a single membrane composed of albuminose; in its young state it contains a fluid plasma, which may continue as such during the period of mere growth and multiplication, or be displaced by the special product natural to the cell. It may multiply by binary subdivision, by the breaking up of its contents into particles, or by the aggregation of the

molecules of the circulating fluids into masses whose exterior forms a cell wall, the interior becoming liquefied cell contents; this last can take place only in highly organized animals. The simple membrane of cells and basement membrane are structureless; after this come the granules or molecules, very minute, floating free like those in the chyle, or enclosed as in the nerve corpuscles, gland cells, and pigment cells; next to these simple structures come nuclei or cytoblasts, cells within cells, and sometimes with granular nucleoli; the blood corpuscles are vesicular nuclei, with walls of simple membrane, without nucleoli; the epithelium and pigment cells have nucleoli; the nuclei of the lymph and chyle corpuscles appear granular. Free nuclei are found in the gastric juice, in the gray cerebral substance, and in some quickly growing tumors; nuclei in cells (and each cell generally contains only a single nucleus) appear to be in contact with the cell wall, without any relation to the centre of the cell. The walls of animal cells coalesce to form tubes and sheaths, while in plants, according to Quekett, the cell wall is always present in the oldest and hardest tissues; and in the former, except in the true cellular tissues, the walls disappear and no trace may be left of the nucleus or nucleolus; in other cases the nuclei may remain attached to the inner surface of the wall. Nuclei are generally oval or round, and do not conform themselves to the different shapes of cells; but they are sometimes elongated and divided. In the fully developed blood corpuscles the nucleus has disappeared; in other instances, the disappearance of the nucleus is a sign of degeneration of tissue; in the yolk and milk cells, and in the cell products of disease, the contents are granular. In the chyle and lymph corpuscles the reproductive granules are set free by the bursting of the cell wall, and are in their turn developed into cells at the expense of the organizable materials of the fluids in which they float; similar granules in the plastic lymph of inflamed surfaces give rise to successive generations of cells by which the healing process is effected. The nucleus, where it exists, seems to be the chief instrument of the functional activity of the cell. In many cases the multiplication of cells is effected by the division of the nucleus, each portion giving origin to a new cell, as in the case of growing cartilage; where rapid growth is needed, and for a tissue of only temporary duration, a cluster of secondary cells is produced in the parent cell by the minute subdivision of the nucleus, as in the case of the cells of secretion in the glandular organs, and, according to Dr. Barry, of the primary development of the embryo; but in all cases cells must take their origin in germs prepared by a previously existing cell.—As the cell is the type of organization, we must expect to find in it the first rudiments of the embryo; the cell containing these rudiments is the ovum or egg; it is a cell enclosing a second, within which is a third, and so on, of granular consistence; the first is the vitelline

ganizing processes connected chiefly with the cell wall. The corpuscles of the blood are formed in the first instance from the embryo cells of the vegetative layer in mammals and birds, and of the inner surface of the vitelline membrane in the lower vertebrates. The cells of bone, of the brain, and of cartilage, have already been described under those heads.—The principal tissues in which cells continually exist are in fat, coloring matter, skin and mucous membrane, and secreting glands. Adipose tissue consists of cells with walls of structureless membrane, containing fat, globular when single, variously flattened under pressure, and without perceptible nucleus except in the embryo; this tissue is capable of rapid growth, as is familiarly seen in fatty tumors. Coloring matter in vegetables may exist in the cell wall, as in some ferns, or in a contained fluid, as in chlorophyl generally; fluid coloring matter exists in the blood cells, but pigment usually occurs in the form of granules. The pigment of the choroid coat of the eye consists of innumerable granules, about  $\frac{1}{100}$  of an inch in diameter, enclosed in 6-sided cells, the depth of color being in proportion to the quantity collected in a certain space within the cell: the coloring matter of the skin

constituent gland cells. The cells are developed in the male male in the ovaries. Ab testinal mucous memb concerned, ed thro cells, which digestion, and re tory process, convey during the presence of select, absorb, and prepare al, and then by their rupt lacteals; in the blood, the puscles convert the albu fibrine, which they set stant dissolution; and another set of cells, tween oxygen and sues, or perform As each cell has its period understand the nature of the of growth and di ganism. The absorbing elaborating cells are existence: the cells of o ical: t. as of t of the of nolo d

sed functional activity. The faster any tissue made to live, the shorter will be its life, the repose necessary for reparation being. As in the lower fungi and the early of embryonic development, cells occasionally proceed to the work of multiplication at extreme rapidity, neither the primary nor secondary cells undergoing any further division; this distinguishes fungoid or malignant growths from healthy structure.—For cell pathology and minute investigations into the history of the cell, the reader is referred to Dr. Bennett's "Essay;" he regards pathology as an extension of physiology, it being impossible to distinguish the cells of either as to their original aspect; the difference relates to function only, not to their structure.

**OELLAMARE, ANTONIO GIUDICE**, prince of Giovenazzo, a Spanish diplomatist of Neapolitan origin, born in 1657, in Naples, died Jan. 16, 1733, in Seville. Brought up at the court of Charles II. of Spain, he afterward fought in the battles of his successor, Philip V., against the imperialists. Taken prisoner in 1706, he was detained until 1712. Three years after his return to Spain he was sent to France as ambassador. Here he joined the conspiracies planned against the duke of Orléans, with a view of vesting the regency of France in Philip of Spain, but the plot was discovered, and the seizure of Cellamare's despatches laid bare the whole details. He was driven out of France at once, and on his return was appointed captain-general of Old Castile, which he retained until his death.

**CELLARER** (Lat. *cellarius*), under the Roman emperors, a functionary who examined the accounts, and to whom was committed the care of their domestic affairs. The name was subsequently given to the purveyors or agents for palaces and monasteries. The cellarer was one of the 4 great officers of monasteries, and had under his orders the bake-house and the brew-house. He regulated the harvesting and storing of corn, and managed the whole economy of provisions. His compensation was  $\frac{1}{4}$  of the grain received, and a furred gown. The office was sometimes held by persons of illustrious birth; thus Philip of Savoy, in 1243, was cellarer to the archbishop of Vienna.

**CELLARIUS, CHRISTOPH**, a learned German, born at Schmalkalden, Nov. 22, 1638, died in Halle, June 4, 1707. He devoted himself solely to the study of the oriental languages and literature, that it is related of him that during 25 years he spent at the university of Halle, he once went out for a walk in the streets. He translated more than 20 Greek and Latin classical works, and wrote several volumes on the climate, geography, history, and languages of oriental countries.

**CELLE** (Ger. *Zelle*), capital of the bailiwick of the same name in Hanover, district of Lüneburg, on the Aller, which is here navigable, and near the Hanover and Brunswick railway; pop. 1000. It is a well-built and paved town, the

seat of the supreme court of Hanover, contains churches of different denominations, an old castle formerly occupied by the dukes of Lüneburg, a medical college, 2 public libraries, an agricultural society, and various other public institutions. Celle is also noted for its annual horse races. The famous stud of the king of Hanover and the house of correction are near the town. In the castle park is the mausoleum of Matilda, queen of Denmark, who died here. The inhabitants are employed in the manufacture of tobacco, cigars, stearine, &c., and carry on a brisk transit trade in wool, wax, honey, and wood.

**OELLINI, BENVENUTO**, an Italian artist, born in Florence, in 1500, died there Feb. 25, 1570. Intended for the musical profession, to which his father was devoted, he gave the preference to the pursuits of a goldworker and engraver. Endowed by nature with a skilful hand and a fertile fancy, he soon distinguished himself in chasing sword handles, cutting dies, and engraving medals. But his headstrong disposition tended to involve him in brawls and quarrels, which were free however from malice, and frequently blended with a charming vein of drollery and audacity. His debut in the sphere of art went thus hand in hand with his exploits in the field of duelling, and at the age of 15, when his genius had already excited the admiration of his townsmen, he was banished to Sienna. After wandering for some time from one town to another, he eventually found his way to Rome, where a gold medal of Clement VII., of which he had furnished the die, secured him a favorable reception at the papal court. The pope took him into his service, and this position gained him abundant employment in cutting seals for many eminent prelates. He also took part in the defence of the castle of Sant' Angelo, Rome being at that time the theatre of conflicts between Charles V. and Francis I., and Cellini was fond of boasting that he had killed the constable of Bourbon and the prince of Orange. At any rate, when he left Rome he had added the laurels of a soldier to those of an artist. At Mantua, where he remained until an affray compelled him to leave the town, he became acquainted with Giulio Romano, and through him with the grand duke, who gave him some commissions. On his return to Florence, where his military exploits at Rome had reinstated him in the good graces of the authorities, he formed an intimacy with Michel Angelo; but his violent temper again embroiled him in a quarrel, which compelled him to leave in disguise for Rome. While at Florence, he devoted himself principally to the execution of medals, the best of which are Hercules and the Nemean lion, and Atlas supporting the globe. At Rome, he was appointed engraver to the mint, but soon found himself again in trouble. This time a mistress of his named Angelica, who had fled to Naples, seems to have roused his wrath. He followed her to Naples, but on receiving the pardon of the new pope (Paul III.) returned to

migration or irruption of barbarians ever travelled, on the most extended scale, from the west easterly, although in some irregular local movements, in working southward, they may have temporarily assumed an easterly direction—as, in entering Italy from the northward, they must necessarily have done, owing to the trend of the land. If, however, as there is much cause to believe, the Cimmerii, who entered and long held the Crimea, were Cimbric Celts, we know that so long ago as the reign of Ardys, king of Lydia (678-'29 B. C.), they entered Asia Minor, necessarily from the eastward, since they were land journeyers and not seafarers, and held Sardis until expelled from it by Alyattes, the contemporary of Cyaxares, in the end of the 6th century before Christ. But they held yet longer to the Crimea. It has been stated above that the Gauls and the Cimbri are both Celts, and in order to show that fact satisfactorily, it is necessary to have recourse both to etymology and ethnology; this, however, can be done briefly and simply. In relation to the first, it is necessary to remark that much difficulty has arisen in tracing the origin of words deducible from the Greek, from our having adopted the Latin, which even in that la-

months all Rome with the capitol, and that which v phi—were commanded by it is delivered to us by the historians, is identical with the valent to king or chieftain. various facts we find that, the 8d century before Christ knew the Kelts as settled west of Spain and along the of France, and that a vast simultaneous irruption poured down upon civilization northward. Naturally, the invaders to which they were known and to have travelled eastward, instead really did, from the only coming upon the civilization. The same is vailed in reference to Herodotus also ascribe ward Asia Minor. e than that he Ori a after tl

than to the family ; little constructive tendency to legislation, to art, unless modest music and to wild ballad poetry ; noble female chastity, and great adherence to the race, its habits and traditions.

**CELTIBERIANS**, **CELTIBERI**, a people of the north of Spain, who seem to have occupied the northern and portions of Old and New Castile and Navarre. Every thing concerning their origin, the places whence they came, their connection with other races, is extremely obscure. According to Diodorus Siculus they were composed of 2 nations, the Celtiberi and Iberi, whence they were called Celtiberi ; but whether he intends to say that the name, for it deserves that name, was made by a fusion of 2 tribes or races into one national polity, or that the whole people gradually grown up from the mixture of 2 by intermarriage, does not appear. They were found in Spain, when they dispossessed the Thagiuinians, 2 Celtic tribes, as such, still pure and unmixed, one on the Anas or Guadiana, in the south-west of Spain, and one on the Douro, in the north-west of Portugal, and these the Celtiberians, who occupied the country lying about the head waters of the Tagus, extending northward to the Ebro in the north of Saragossa, and nearly surrounded by the mountainous ranges of the Castilian mountains, Sierra Blanca, and the eastern roots of the Pyrenees. The 2 other Celtic tribes remaining, it is worthy of remark, are situated in the most difficult mountain fastnesses, the former on the spurs of the Vilheercas or Toledo mountains, the latter in the intricate and almost impregnable hill country of Galicia and Asturias. "With regard to these 3 nations," says Diodorus, "it seems to have been the general opinion that the Celts crossed over the Pyrenees as well as the Alps, and that from their intermixture with the Iberians, whom they conquered, sprang the nation in whose composition this intermixture is expressed ; while a part of their host settled on the Anas, and another of these went forward to the Minus. The slightest trace is to be found of any thing concerning this expedition. The notion is probably nothing more than a conjecture of foreign historians with regard to a people which had spread so far beyond its limits on other sides."

**CEMENTATION**, the term applied to the process of steel, which consists in covering iron with fine charcoal, and subjecting the whole to long continued red heats till a sufficient amount of the carbon has entered into and combined with the iron. It is also applied to similar processes.

**CEMENTS**, a term applied to those bodies which are capable by their interposition of uniting heterogeneous or heterogeneous substances. Cementation may result either from chemical combination, or it may be simply mechanical, and the adhesiveness of the cement, by which it is excluded from the surfaces to be united.

In the former category may be classed the hydraulic or building cements, used in architecture, and formed from those argillaceous limestones which on calcination are rendered capable of setting under water with rapidity, of acquiring great hardness in a short time, and of being employed without the admixture of any foreign substances. In the latter class the most prominent are the bituminous, oleaginous, and resinous, beside miscellaneous cements, a great number of which are employed in the different branches of the industrial arts. Among the hydraulic cements, the most widely known are the Roman, Portland, Medina, and Mulgrave in England, and the Kingston and Rosendale cements in this country.—Roman cement was first manufactured by Mr. Parker of London, from the septaria nodules of the London clay formation, found in the island of Sheppey ; his process, which was patented in 1796, consisted in calcining the stone nearly to the point of vitrification, and then reducing it to powder by crushing ; he applied the term Roman to this preparation from its similarity to that formed by the ancient Romans from pozzolana and trass, substances of volcanic origin, and nearly allied to the septaria in their chemical constitution. At a later date it was discovered that the septaria of other localities furnished a cement similar to Parker's. Medina Cement is prepared from nodules found in Hampshire, while Mulgrave or Atkinson's cement is formed from the argillaceous limestones of the lias. Portland cement is so termed from its similarity in color to the Portland stone ; it is not properly a cement, but an artificial hydraulic lime composed of a mixture of clay and chalk from the valley of the Medway ; the materials are ground together under water, and afterward dried and burnt in proper kilns. Portland cement is noted for its extraordinary hardness and tenacity, but, as it permanently expands in setting, must not be used where such a property would interfere with the solidity of the work ; in external plastering it is of great value.—In the United States hydraulic cements are obtained in numerous localities. Cements of good quality are manufactured in Virginia, on the banks of the Potomac at Sheppardstown, and in the vicinity of the Natural Bridge, also in Kentucky near Louisville, and in many other places where the silicious magnesian limestones are found. Those from the state of New York, however, are considered the best, particularly the Kingston and Rosendale cements, manufactured in Ulster co. ; these were used in the construction of the Croton aqueduct, and of many other important public works throughout the country. The cement stone of Kingston yielded the following results according to an analysis of Dr. Beck :

	Before calcination.	After calcination.
Carbonic acid.....	34.90	5.00
Lime.....	25.50	37.00
Magnesia.....	12.35	10.05
Silica.....	15.57	22.75
Alumina.....	2.12	12.40
Peroxide of iron.....	2.95	2.50
Loss, &c.....	1.90	1.90

An analysis of the Sheppey stone, from which Parker's cement is obtained, gives:

Carbonate of lime.....	0.690
Magnesia .....	0.002
Oxide of iron.....	0.037
Oxide of manganese.....	0.012
Silica.....	0.180
Alumina.....	0.066
Water.....	0.018

As a general rule it may be stated that a limestone must contain from 25 to 35 per cent. of clay (silicate of alumina), in order to yield a good, quick-setting cement, though 10 to 12 per cent. of clay will suffice to give it hydraulic properties. Great difference of opinion has existed in regard to this subject; some have ascribed the hydraulic property to the presence of oxide of iron, and others to the oxide of manganese, to silica, alumina, magnesia, and soda. Berthier and Vicat, however, found that the presence of silica was indispensable, and they assigned no importance whatever to the oxides of iron and manganese. Without entering upon a full consideration of all the substances involved, it will be sufficient to say that certain earthy substances, and especially silica, combine with the lime which is produced by the calcination of the carbonate of lime contained in the cement stones, and that the silicate thus formed, absorbing water, becomes solid.—The general name of Roman cement is often, though erroneously, applied to all the natural hydraulic cements, and the process of preparation is essentially the same. They are burned in kilns, and a lower degree of heat is employed than that recommended by Parker; the cement being under burnt, economy is effected in the process of grinding. In burning, the stone loses about  $\frac{1}{4}$  of its weight, and acquires a brown tinge, differing in shade according to the kind of stone used; it is then soft to the touch, and leaves a very fine dust upon the fingers. The blocks of cement might be preserved for a long while in a dry room, in the same state in which they come from the kiln; such is the difficulty with which they absorb water that Gen. Pasley pronounced them incapable of so doing. For use, however, the cement must be ground, and is then put in casks well closed, since exposure to the air rapidly deteriorates its quality, the powder absorbing water and carbonic acid, and passing into the state of a subcarbonate; its usefulness, however, may be restored by a second burning at a lower degree of heat than in the first instance. M. Petot has observed that when the calcination of cement stones is so extended as to expel all the carbonic acid, the resulting powder is perfectly inert, showing a remarkable difference between this class of limestones and those which produce the common lime. This property should be borne in mind in all experiments made to test limestones for hydraulic cement. Cement should be ground very fine; the French engineers require that the sieve through which it passes shall be of No. 2 of their wire gauze, and contain 185 meshes to the square of a side of 4 inches. The specific gravity of the cement

powder varies from 0.85 to 1; the lighter the best. No little skill and attention are required in the use of these natural cements if they are not brought to a proper consistence or if the water be used too sparingly or abundantly, or if allowed to stand after made, they will solidify unequally, and adhere badly to the materials. But a quantity of water is necessary to work cements to their greatest point of resistance. According to Treussart, the best proportion is 1 of water to 8 of cement by volume; mixing, the cement should be beaten frequently, since the more it is stirred before setting commences, the harder it becomes. Time of setting varies considerably, being with sea water than with fresh, and retarded in proportion to the amount of sand employed. When used pure, it will often set in 5 or 6 minutes, and the time should not exceed half an hour, or when used under water 1 hour. If  $\frac{1}{2}$  to 2 parts of sand be added to 1 of cement, the mixture will set in from 10 minutes to 1 hour 18 minutes in the proportionally longer time under water. In sea water, and especially if the same be used in mixing the cement, the time tends to 24 hours. Pure cement, after exposure of 20 days to the air, offers a resistance of about 54 lbs. to the square inch, if it be mixed with half its bulk of sand the resistance falls to 37 lbs., and with an equal bulk to 27 lbs., showing in this respect a great difference from the limes. The resistance afforded by pure cement against the pressure of stones upon their beds may safely be taken at 9 lbs. per square inch, though it may reach 18 lbs. The natural cements are employed to the best advantage without sand, used in works under water, or where a great crushing weight is to be brought upon them. For cornices, or coatings exposed to the weather, we may combine 2 parts of sand with 3 of cement, and for perpendicular faces of sand with 2 of cement, being careful to prevent the formation of fissures, which would destroy the coating to the effects of frost and wind. Cement adheres very strongly to iron, still more so to granite, and most bricks.—Beside the cements already mentioned many others may be obtained, either by the calcination of the hydraulic limes, which produces a more rapid setting and a greater hardness, or by the mixture of burnt clay with the rich limes; the latter do not set so rapidly, as is the case with the former, but are inferior in point of hardness; they are, however, often used to advantage when mixed with the slow-setting limes, and employed in situations, as in the lining of water-tanks; still they are generally considered inferior to the natural cements, and their employment can only be advocated on the score of economy. Another class of cements are those which contain gypsum or plaster of Paris, instead of hydraulic lime; in this case the hard-

to a union of the cement with water, and not to the formation of a silicate, as in the former cements; as gypsum alone, however, never acquires any great degree of tenacity, it is employed in combination with alum. In Keene's cement, powdered gypsum is mixed with a solution of alum, and then heated till all the water in combination is dissipated; it is then powdered, and when used, slaked by a solution of alum in 12 or 13 parts of water. Martin's cement differs from the above only in adding to the original compound a portion of carbonate of soda, or carbonate of potassa, and in using a greater degree of heat; while in Parian cement borax is substituted for the carbonate of soda or potassa. These are useful in floorings, skirtings, &c., and especially where damp and vermin are to be apprehended; they may be employed like stucco in cementing walls, and their surface afterward embellished by delineations similar to those of fresco painting. Stucco is used for coating walls, ornamenting ceilings, &c., and consists of powdered gypsum, mixed with a solution of glue or gelatine. Scagliola is somewhat similar, and derives its name from the numerous splinters or *scaglioli* of marble used in the work. (See STUCCO.)—Bituminous cements are employed as substitutes for flagging in the paving of streets, and for protecting the extrados of arches from the effects of water, &c. The former application is limited, but for the latter purpose they are of great utility, since in all new masonry there are movements which fissure the coatings executed in lime or hydraulic cements, to say nothing of the crevices produced by the unequal contractions and shrinkages of the cements, so that it is almost impossible to render such coatings impermeable; these defects are admirably remedied by the elasticity of the bituminous cements; small crevices often unite of themselves, and large repairs, when necessary, are easily executed. These cements are obtained from the natural asphaltum; mixed with chalk or other form of carbonate of lime, it is best adapted to works which are exposed to the effects of the sun; alone, it would melt in such situations, but for subterranean works is considered preferable. (See ASPHALTUM.) The cement is spread with trowels, and as far as possible formed into slabs of about 3 feet in width; it should be evenly spread and compressed, and fine sand then sprinkled on the surface, and worked in with the trowel, taking care to fill any crevices that may be formed by air bubbles with cement, and not with sand. For coating arches, a thickness of  $\frac{3}{4}$  to  $\frac{1}{2}$  an inch is sufficient, giving a quantity of about  $4\frac{1}{2}$  lbs. to the square yard; it is also advisable to lay the cement upon a bed of concrete or mortar; in street paving this precaution is indispensable, and the thickness of coating must be fully  $\frac{3}{4}$  of an inch; it is also well to add a little quicklime to the boiling asphaltum, to prevent the cement becoming too soft under the heat of the sun's rays. The surface upon

which the cement is employed must always be dry, and it should be used as hot as possible. Should the asphaltum be found too brittle, a quantity of mineral pitch or petroleum may be added to correct this defect, but coal tar or vegetable pitch must on no account be used. These latter, though greatly inferior to the natural bitumens, may in some cases serve as tolerable substitutes for them; though deficient in elasticity and durability, they yet make good coatings for vaults, &c. For pavements, however, they are not at all adapted. They are prepared by mixing powdered calcareous stone with the boiling pitch or tar, the relative proportions being obtained in each case by direct experiment; the stone must be well dried, for if wet, the vapor generated by it would render the cement porous; and care must also be taken lest the stone be converted into quicklime, as this takes place with comparative facility, owing to its comminuted state. They are to be used in the same way with the other cements, except that it is desirable to employ greater thicknesses.—The oleaginous cements were formerly much used, under the name of mastics, for the purpose of ornamental decorations; they furnish a smooth, close-grained surface, but require repainting every 3 or 4 years. The expense and difficulty of manipulation have caused them to be seldom employed at the present day. The most widely known mastics are those of Hamelin in England, and the mastic *de Dhil* in France; their exact composition is kept secret, but the main ingredients are pounded brick-dust or well-burnt clay, litharge, the red protoxide of lead, and linseed oil.—The cements used on the continent of Europe for mosaic work are of 3 kinds. The first is bituminous, being composed of pitch mixed with a black earth, and is used in setting the large *tesserae* in floors; the second is oleaginous, employed for setting stones of middling dimensions, and made of the calcareous stone of Tivoli, and of oil; while the third, for the more delicate mosaics of pieces of glass, is composed of lime, brick-dust, gum andragan, and the whites of eggs.—Among the interminable list of miscellaneous cements, we find a very useful one for joining broken pieces of glass or china-ware; it is termed diamond cement, and is prepared by steeping isinglass in water till it swells, and then dissolving it in proof spirit, to which is added a little gum resin, gum ammoniacum, or resin mastic, dissolved in the smallest possible quantity of alcohol; it partially resists moisture, and should be gently heated before applied. Hatle's cement for the same purpose consists of 2 parts of shell-lac dissolved in 1 part of oil of turpentine, and cast into sticks. Keller's cement is prepared according to the following formula: Steep 2 parts of finely-chopped fish glue for 24 hours in 16 parts of water, then boil till the liquor is reduced to 8; add 8 parts of alcohol, and strain the whole through linen; while still warm, mix with a solution of 1 part of mastic in 9 of alcohol, and  $\frac{1}{2}$  a part of gum

with a hot cement of rosin, wax, and lime. Varley's cement is formed by melting 16 parts of rosin and 1 of beeswax with 16 of whiting previously well dried by having been heated to redness, and stirring the whole well during the fusion. Singer's cement, for connecting articles of brass and glass, is composed of 5 lbs. of rosin, 1 of beeswax, 1 of red ochre, and 2 tablespoonfuls of plaster of Paris, all melted together. According to Ure, a cheaper compound, and one well adapted for cementing voltaic plates into wooden troughs, is made of 6 lbs. of rosin, 1 of red ochre,  $\frac{1}{2}$  lb. of plaster of Paris, and  $\frac{1}{2}$  lb. of linseed oil, the ochre and plaster to be calcined beforehand, and added to the other ingredients while in fusion. White wax, rosin, and Canada balsam form a cement nearly colorless. Cameos of white enamel or colored glass may be joined to a real stone, to give the appearance of an onyx, by the use of resin mastic, and in the same manner false backs or doublets may be connected to stones so as to alter their hue. In these the cements must be softened by heat before being applied. Iron pipes are often cemented by a paste of iron filings and chloride of ammonium, moistened with water: the oxidation of the iron expands

opolis of Paris, is situated N. E. city, and extends from the boundary almost to that of Amandiers. It was ed into a cemetery by Napoleon I., ins the tombs of Abelard and Heloise, ine, Molière, Beaumarchais, Delille, allini, Weber, Laplace, Cuvier, Arago, Constant, Börne, Royer-Collard, Mar, the painter David, Sieyès, Barras, Soulié, Balzac, and others of the most hed men of France. Its highest eleva- nds the city on one side and the sur- country on the other, and its hills and re covered with every variety of obelisk, pyramid, funeral vase, and l flowers and garlands. The ceme- Russia are usually distant from cities es, and planted with tall pines. Among oted and beautiful cemeteries in the ates are Mount Auburn, near Boston, (CAMBRIDGE), Greenwood, in Brook- aurel Hill, near Philadelphia.

, BEATRICE, a Roman maiden of the ury, noted for her tragic fate. Her unt Nicolo Cenci, was a man notorious ad character and fiendish passions, uld have brought him to the block, if use fortune had not enabled him to several occasions from the hands of In the latter part of his life he retired second wife Lucrezia, with Beatrice oungest brother Bernardo, to the castle a, situated in a desolate spot on the ills, near the Neapolitan frontier; and that savage rock, the castle of Pe- here "at noonday 'tis twilight, and blackest night," the monster, after aused the death of 2 of his sons, ad a diabolical outrage upon the his own daughter. Beatrice brought before Pope Clement VIII., but as her r justice remained unheeded, the as- n of her unnatural parent was deter- on by her stepmother, her brother, over. According to other and more by authorities, Beatrice and her rela- no part in the assassination, which is ave been perpetrated by some of the mies of the old man, who was exe- l over the country. But, however have been, Beatrice was accused of and after having been subjected to the uciating tortures, was executed by the Sept. 11, 1599. Her stepmother Lu- her elder brother Giacomo were also to death. Her younger brother Ber- fe was spared on account of his ex- uth. When the executioner bound

Beatrice said: "You bind my body action, but my soul for immortality." ie torture she is said to have replied to rrogation of the judge, "It is true," 'O God, thou knowest if this be true." is there was not a particle of evidence er. The death of Beatrice sent a horror through Rome. Many of

the most illustrious families had in vain sought the pope to spare her life. Pope Paul V. confiscated the Cenci estates, including the villa, which, under the name of Villa Borghese, has since acquired a world-wide celebrity. More than one life was lost in attempts to rescue Beatrice. Her remains were interred at Montorio in the church of San Pietro. Guido's celebrated portrait, in the Palazzo Barberini at Rome, is said to have been taken immediately before her execution. In Whiteside's "Italy," the true story of Beatrice Cenci is related after the original MSS., which for a long time were preserved with the greatest secrecy, on account of the connection of the Cenci with many of the most influential families of Rome. Muratori's "Annals" constitute another authority, which is frequently referred to on the subject of Beatrice. The French author De Custine dramatized the story, but the greatest work on the subject is Shelley's, who represents Beatrice as implicated in the murder of her father. Mr. Whiteside, however, has fully established the fact that the beautiful girl was sinned against, but no sinner. An English translation of Guerrazzi's novel of "Beatrice Cenci," by Mrs. Watts Sherman, appeared at New York in 1858, simultaneously with one by Signor Monti, of Harvard university, Cambridge.

CENEDA (anc. *Cenitense Castrum*), a Venetian town of the province of Treviso, on the rivers Meschis and Piave; pop. 5,200. It is the see of a bishopric, and possesses a cathedral, several churches, manufactories of leather, woollens, and paper, and several mineral springs.

CENIS, MOUNT, a remarkable mountain at the junction of the Graian with the Cottian Alps. It is an elevated plateau 6,778 feet above the sea-level, with a peak rising to the height of 11,454 feet. On the plateau is a fine lake (La Ramasse), noted for an abundant supply of trout. The mountain lies between the province of Susa in Piedmont and that of Maurienne in Savoy. Over it is one of the most noted Alpine passes. It first appears in history in the times of Pepin. It was over the pass of Cenis that Pepin led the French army (755) against Astolphus, king of the Lombards, in aid of Pope Stephen III., in which service, by the promise of the distressed pope, Pepin earned an inheritance of spiritual rewards for himself and all the French nation. Nearly 1,000 years later Catinat, marshal of France, led his army over this pass, in the wars of Louis XIV. Catinat improved the Cenis pass somewhat, though it was still of difficult transit, and only for mules. In order to facilitate the intercourse across the Alps, Napoleon ordered a road to be laid out and constructed 18 feet wide for a distance of 80 m., so that the pass of Cenis is now less difficult and dangerous. Napoleon's road leads from Lans-le-Bourg to Susa. It was constructed at a cost of more than 7,000,000 francs. There is a toll levied on passengers, to defray the expenses of the

ing incense, used in the celebration of religious rites by the ancient Hebrews, Greeks, and Romans, and still retained in the Catholic church. The Jewish censor appears to have been a sort of chafing-dish, with or without handles, which the high priest carried into the sanctuary or placed on the altar of incense. That used in the Catholic church is a vessel shaped much like a goblet, with a perforated lid, swung by long chains, and carried by an acolyte. Josephus tells us that Solomon made 20,000 golden censers for the temple of Jerusalem.

CENSOR (Lat. *censere*, to estimate), the title of Roman magistrates of high dignity and great influence, instituted in the year 443 B. C. The office was vested in 2 persons, originally elected for 5 years, from and by the patrician order; but later changes introduced by the dictator Mamerus, 438 B. C., and afterward, reduced the term of the office to 18 months, without changing the period of election, and made it attainable by plebeians, of whom Rutillius, who had also been the first dictator of that order, was the first elevated to this dignity (350); and in 182, even both censors were plebeians. They had all the ensigns of consular dignity except

exercise over his destiny, and of the periods of his life. He then of religious rites, and matters relating to chronology, and cosmography has been of considerable value to ancient chronology. By it the dates of the era of Nabonassar and of other dates have been fixed, and Censorius has been named by Scaliger as *titulus temporum vindex*. The title of his work was that of Bologninus, last is a German edition, by Gräff.

**CENSORSHIP OF THE PRESS**—the action by which books, pamphlets, papers are subjected to the examination of certain civil or ecclesiastical officers empowered to authorize or forbid publication. Such a regulation was suggested by the example of the censorship of Greece and Rome. Thus all the works of Protagoras were condemned at Athens by sentence of the areopagus, he had expressed doubts concerning the existence of the gods. Satirical works on magic were often condemned by the Roman emperors, and Dionysius the sacred books of the Christians

air works before publication to the of the higher clergy. The first emi-  
 nence of this kind was that of Autpert,  
 stine monk, who in 768 sent his  
 on of the Apocalypse" to Pope  
 I., begging him to publish the work  
 it known. The invention of print-  
 e increasing number of books called  
 and stricter prescriptions of censor-  
 there still remain copies of books  
 1479 and 1480 which are accompa-  
 soleinn approbations and attestations  
 vor. In 1486 Berthold, archbishop  
 issued a mandate forbidding the pub-  
 any work in the German language  
 should be first read and approved by  
 ensors whom he appointed. In 1501  
 ander VI. addressed a bull to the  
 s of Cologne, Mentz, Treves, and  
 3, according to which no book should  
 without special express license from  
 . Finally, in 1515, the council of the  
 assembled at Rome, decreed that in  
 books should be printed in any town  
 unless they were previously inspected  
 lly examined by the bishop of the  
 his deputy, or by the inquisitor of  
 e or his deputy, or if at Rome by the  
 r and the master of the sacred palace.  
 rk which was approved was to be  
 ned by the hand of the censor, and  
 ation not thus countersigned was to  
 and its author or editor excommuni-  
 us was a general censorship of the  
 summated by the Roman Catholic  
 hich has since been enforced by that  
 countries where it has had the power.  
 t of Prohibited Books" was begun by  
 l of Trent in 1546, and has been from  
 ne republished and enlarged. It has  
 'Index of Expurgated Books."—In  
 where the reformation prevailed, the  
 was not abolished. Licensers of  
 e appointed in England, who were  
 st part bishops; and in the reign of  
 complaints were laid before the house  
 ns against Archbishop Laud and his  
 because, as was alleged, it was im-  
 o obtain from them permission to  
 book written against popery. A  
 stem of censorship was established  
 ee of the star chamber, dated July  
 which remained in force during the  
 and was confirmed by an act of par-  
 1643. It was against this act that  
 ote his "Areopagitica: a Speech for  
 y of Unlicensed Printing." "Para-  
 'itself was in danger of being sup-  
 cause the simile of Satan compared  
 ising sun, in the first book, was sup-  
 contain a political allusion. Parlia-  
 several measures against "scandalous,  
 libelous, and unlicensed pamphlets."  
 e council at Whitehall ordered that no  
 ould print any matter of public news  
 ence without leave of the secretary

of state. The licensing system, and with it the  
 censorship of the press, was abolished in Eng-  
 land in 1694 in the reign of William and Mary,  
 but the question of its revival was agitated in  
 parliament some time later,—A general censor-  
 ship of the press existed under the old French  
 monarchy. Originally in the hands of the  
 bishops, it passed by degrees to the doctors of  
 the faculty of theology; but this faculty becom-  
 ing divided into parties on matters of contro-  
 versy, the chancellor of the kingdom took the  
 censorship from it in 1653. He appointed 4  
 royal censors with an annual stipend to examine  
 all works without distinction, and no writing  
 could be printed or sold, and no dramatic piece  
 performed, unless approved by one of them.  
 At the outbreak of the revolution the censor-  
 ship was abolished and entire liberty of the  
 press proclaimed, but in the reign of violence  
 which followed there was no safety for obnox-  
 ious journals or writers. Napoleon during the  
 consulate limited the freedom of the press to  
 works of a certain size, but subjected news-  
 papers and pamphlets to a strict inspection.  
 By a decree of the council of state in 1810, a  
 complicated system of censorship was revived  
 in France. Even after a book had been exam-  
 ined, approved, and printed, it could be seized  
 by the minister of police and its sale stopped, a  
 memorable instance of which was the destruc-  
 tion of the whole first edition of Madame de  
 Staël's *De l'Allemagne*. After various modifi-  
 cations of the censorship, Charles X., upon  
 coming to the throne, abolished it altogether,  
 but soon after suspended the liberty of the  
 periodical press. By a law of 1835 the pro-  
 prietors of political journals are obliged to de-  
 posit a considerable sum in the treasury as  
 security for their good behavior. Under the  
 empire of Louis Napoleon the Parisian news-  
 papers are subjected to strict supervision, and  
 if not satisfactorily conducted may be suppress-  
 ed.—A general censorship of the press is main-  
 tained in the absolute monarchy of Russia. In  
 some of the Italian states an ecclesiastical and  
 a political censorship exist together. By the  
 Spanish constitution of 1837 the previous cen-  
 sorship was abolished, and all Spaniards may  
 print their thoughts freely, subject only to the  
 laws. The determination of offences committed  
 by means of the press belongs to juries em-  
 panelled for that purpose. In the republics of  
 Switzerland, since 1830, no censorship has  
 existed, but the liberty of the newspaper press  
 is very much restricted by laws. By the con-  
 stitution of the kingdom of Greece of 1827,  
 the Hellenes have the right of publishing freely  
 their thoughts, abstaining however from viola-  
 tions of decency, from personal calumny, and  
 from attacking the principles of the Christian  
 religion. In Sweden, Norway, the Netherlands,  
 Belgium, and Denmark, no authoritative cen-  
 sorship exists, but upon those who offend  
 through the press penalties of various degrees  
 of severity are imposed. These penalties are  
 most rigorous in Denmark. The liberty of the

There are laws against publications of a scandalously immoral character, but in general the only restraint upon printing or circulating any class of books is found in the public sentiment.

CENSUS, a registration of persons and their property, which in some states constitutes their claim to citizenship, or to dignities attainable only by members of certain classes. That the ancient Hebrews and their families were numbered by age and sex, we have positive proof in the sacred writings, the enumeration of the people having been enjoined on more than one occasion. The most ancient statistical record extant, derived from an enumeration of the people, is that of Moses in the wilderness.—According to the constitution of Solon, the citizens of Athens were divided and registered into 4 classes (*τιμηματα, τελη*), according to the amount of their taxable property, that is to say, of their income. The 1st consisted of the *Pentacosiomedimni*, or persons having a revenue of 500 medimni of grain, or as many measures of oil; the 2d and 3d classes, *Hippeis*, or knights, and *Zeugitæ*, comprised the citizens next in wealth; and the 4th, that of the *Thetes*, included all whose income fell short of 200 medimni. Only those

izen had to appear, and to give his name and dwelling, the children, if he had any. His property, under the penalty of being confiscated, and of being sold as a slave. The whole people was divided into 4 classes, each comprising a number of centuries. The 1st class consisted of those worth at least 100 minæ, the 2d of those worth 75, the 3d of those worth 50, the 4th of those worth 25, and the 5th of those worth less than 25. The 6th comprehended all the poor, who were exempted from all taxes and burdens, and were termed *Proletarii*. As each century was bound to maintain 100 soldiers in its name, not from the number of its members, and as the numbers of centuries were 98 in the 1st, 22 in the 2d, 22 in the 3d, 22 in the 4th, and 30 in the 5th, forming but one, was all evident that the burdens were particularly upon the rich, and were compensated by a privilege in the *Comitia Centuriata*, where the magistrates were elected, and the laws were decided.

tions were modified and overthrown, and but gradually restored, may be regarded as an important basis in the great structure of the Roman power, with an expiatory sacrifice of a bull, a ram, and a hog, which were first led 8 times around the Campus Martius. This ceremony, continued in the similar *Suovetaurilia*, was regarded as a purification of the city, or *Iustrum*, which gave the name to the quinquennial period elapsing between one census and another. Subsequently the kings, the consuls, and then the censors presided over the taking of the census, imitating the ceremonies observed by Servius Tullius.—It is mentioned in the “Royal Commentaries” of Peru, by Garcilasso de la Vega (b. vi. ch. 8), that the records of the census by that ingenious people were preserved and illustrated by a fringe work of strings of various sizes, number of strands and colors, knotted “like the girdle of St. Thomas,” by which they could express “the greatest number at which arithmetic could arrive;” and in this manner they described the several castes of population, and their enumeration by age and sex, with a classification, first, those of the age of 70 and upward, then those of 50, “then those by 10 to 10 down to sucking children.” In this way they preserved the record of their married and widowed men and women by age and sex, and in like manner they are represented as taking annually and preserving an account of the warriors of different orders and the agricultural productions and wealth of the people. According to Herrera, the Mexicans were but little if at all behind the Peruvians in their means of understanding the condition of the people by means of the census.—There exists no official record of the population of England previous to the commencement of the present century. The first census of Great Britain was taken in 1801, and the first enumeration of the population of Ireland was made in 1813; but so imperfectly was the work accomplished that statisticians place but little confidence in the correctness of the returns, and the first census upon which they place any great reliance is that of 1821. The census of Great Britain and Ireland is taken every 10 years, and includes the general statistics of population. Attempts have been frequently made to induce the British parliament to enact the necessary law for obtaining the general statistics of the kingdom, but they have been frustrated in the belief that such investigations would be distasteful to the people. England also gives particular attention to the register of births, marriages, and deaths, and has established a bureau of statistics, which publishes annual reports of great value on the movements of the population.—It is claimed by French writers, that a census was taken during the reign of Charles IX. in the 16th century, but no traces of this work are to be found in the French archives, although they profess to give the results. The first census of which the records are extant was taken in 1700, the results

of which were published in 1720. The population of France, by what they claim as their first census, was set down at 20,000,000, whereas by that of 1700, when their territorial extent was much increased, it fell short of that by  $\frac{1}{4}$  a million. The census of 1720 was designed to be very thorough for that early period, and revealed pretty clearly the judicial, military, and ecclesiastical condition of the kingdom, and developed many important facts respecting agriculture, manufactures, and commerce, and the physical features of the country. The next census of France was made in 1762, under Louis XV. The minister Necker and the statistician Moheau both throw doubts upon the accuracy of its statements. A general census was taken in 1800, another in 1805. A royal ordinance in 1822 provided for a general census every 5 years; but in place of an actual enumeration which should have been made in 1826, the number of inhabitants was declared by simply adding to the population of 1822 the excess of births over deaths for the intermediate time, and the result was by royal ordinance declared authentic; a convenient method of avoiding, when it seemed politic, unpalatable revelations. From the time of this intermission the census has been taken with regularity and care. In France the parish or commune sends its report to the chief place of the canton, the canton to the head of its department, who forwards it to the minister of the interior, where are collected the reports of the 86 principal divisions, the 863 districts, the 2,847 cantons, and finally the 36,819 communes, villages, &c. The population is returned by ages, sexes, professions or trades.—In Prussia, statistical investigations have been pursued by the government since the days of Frederick the Great, and the statistical bureau was established in 1816, which has the control of the census, which occurs every 8 years, when the population is registered by age and sex, with the principal domestic animals, schools, and industrial establishments subject to taxation. In this work the principal states of Germany have recently united, and under the charge of Dietrich, the distinguished chief of the statistical bureau at Berlin, there have been prepared and published the statistics of the 39 allied states.—In Sweden, the science of statistics has been more particularly cultivated than in any other country, and the frequent enumeration of the inhabitants has been pursued for near a century with great care. In Sweden originated the earliest mortality tables which are used at the present day.—In Russia, the census was organized in 1723 by Peter the Great, who established during the previous year the general registration of births, marriages, and deaths. It was at that time ordained that the census should be renewed every 20 years. From the early institution of these investigations, and the particular manner with which they have been conducted, we are possessed of a knowledge of the movements of the Russian population for more than a century. The magnitude

THE STATISTICAL COMMISSION OF BELGIUM, under its president the distinguished Quetelet, and was composed of 15 persons eminent for their knowledge in the several specialities to which their attention was severally directed. As might be inferred, the result of their efforts has been the most perfect work on the population and resources of a government ever published in Europe.—The census of the United States presents the unusual fact of being instituted with the constitution of the government, the 1st article of which prescribes a general enumeration of the people within 3 years after the 1st meeting of congress, and within every subsequent term of 10 years thereafter. The agents employed to ascertain and report the elementary facts are the marshals of the several states and territories, who are the only officers connected with police affairs known to the general government. The first census of the United States recorded the names of heads of families, enumerated the free white males of 16 years and upward, the same under 16, gave the number of females, and the number of slaves. The 2d and 3d census distinguished the sexes and colors of free persons, classifying the free males under 10 years of age, those from 10 to 16, 16 to 26,

by law a census board was proposed of the secretary of state, and postmaster-general, with the view to make all preliminary arrangements, provide the necessary schedules, and which of consequence involved census. This board was organized in 1849, and its plan was not adopted by congress for that census, but applicable to those to be taken after the adoption of an amendment. Vinton of Ohio, the ratio of representation was established in advance and for law. The census, which had been under the direction of the secretary of the interior, was transferred to the department of the interior, and Mr. J. C. G. Kenney acted as secretary of the census board. It is the 7th census of the United States, the most thorough ever made in any country. The attention was bestowed, were the plan of great simplicity and convenience, numbering the houses, specifying recording the name, sex, age, color, profession, or occupation of each

person who died within the year previous to the day of enumeration. The statistics of agriculture embrace the number of acres of land improved and uncultivated, its value, with that of the implements and machinery, the number, variety, and value of the live stock, with a full account of all the productions of the field; the value of estate, real and personal; the taxes, number of colleges, academies, and schools, with the number of teachers and pupils, and the revenues; also the statistics of churches, public libraries, and newspapers; those of mines, manufactures, and fisheries were included, so as to give the capital invested, the quantity, kind, and value of raw materials used; the motive power, number of hands of each sex employed, with their wages, and the various products, in quantity, kind, and value. A digest of these statistics is now being compiled under a recent law of congress. The other details have for the most part been published.—From what has been written on this subject, it will be perceived that the census of each country differs essentially in details and in the times when taken, so that it is almost impracticable to institute comparisons between different nations as to the increase of population and the progress of the industrial arts. To remedy, if possible, these differences, and examine into the plans of the European censuses, Mr. Kennedy was sent to Europe in 1851, and after a conference with many of the most eminent statisticians abroad, all of whom readily admitted the importance of a more harmonious action in national investigations of so much interest, it was resolved to hold a congress of statisticians of all nations at Brussels. Three conventions of this nature have already been held at Brussels, Paris, and Vienna, and it is hoped that something important may result from the deliberations of such conferences.—Independent of the federal census, a majority of the states, either in their constitutions or by act of legislature, have made provision for an enumeration of their population respectively. That of Massachusetts is taken in the same years with that of the United States, and as much oftener as the legislature may direct. It is very general and thorough in its investigations. That of New York, embracing population, agriculture, and manufactures, is made decennially at intermediate periods, affording an enumeration every 5 years; so with Illinois, Wisconsin, and Florida. The census of Ohio, Missouri, and Arkansas is taken once in 4 years; Indiana and Alabama, 6; Michigan, South Carolina, and Tennessee, 10; Iowa, 2; Georgia, 7; Texas, 8; Mississippi, irregularly. Virginia, by her new constitution, has provided for a decennial census intermediate with that of the United States, while no provision for a periodical census has been made by the states of Maine, New Hampshire, Vermont, Rhode Island, Connecticut, Pennsylvania, New Jersey, Delaware, Maryland, North Carolina, and Kentucky.

CENT (a contraction of the Latin word *centum*, a hundred), a United States coin of the

value of the  $\frac{1}{100}$  of a dollar, first made of copper under act of congress, 1787, in New Haven. The same year Massachusetts authorized the making of coins of the same value, which was done the next year. The cent with the symbolical head and the inscription of "Liberty" was ordered by congress in 1792, and first coined in 1793. In 1857 a coin composed of 88 parts copper and 12 parts nickel was issued, which, being of smaller size than the old cent and equal in value, is designed to replace it.

CENTAURS, a mythological race of creatures, half man, half horse, and, in addition to this, semi-divine, who were believed especially to inhabit the passes of Mts. Pelion and Ossa and the great plains of the Thessalotis and Pelasgiotis, in upper Greece. They are mentioned 8 times in the Iliad, twice under the appellation *φῆρες*, which is merely the Æolic form of the common Greek word *θηρες* (wild beasts); under which appellation, with the addition of the epithet *θεῖος*, godlike or divine, they are also spoken of by Pindar, and once under their appropriate name *Κενταυροί*. They are also mentioned by name, as centaurs, in the Odyssey. It does not distinctly appear whether, by the writer of the Homeric poems, the centaurs were understood or intended to be received as semi-human, semi-ferine animals, no allusion being made directly to their form or attributes; but the use of the word *φῆρ*, wild beast, as applied to them, which never, so far as is known, is used by any classic writer in speaking of a human being, would seem to be conclusive. The legend concerning the origin of the centaurs is twofold. Ixion being, in consequence of an atrocious crime, in the murder of his father-in-law, Deioneus, refused all intercourse or fellowship with mankind, Jupiter invited him in mere compassion to reside on Olympus. Incapable of gratitude, however, and forgetful of all rules of hospitality, he at once attempted to seduce the wife of his entertainer, Juno. By a concerted plan, however, of the god and goddess, a cloud woman, formed into Juno's semblance and vivified for the time, was substituted for her, and the intrigue proceeded, until the seducer, boasting of his success with the immortals, was bound on an ever-revolving wheel in the abyss of Tartarus, while the cloud became the mother of the centaurs; or, according to the myth as given by Pindar, of a son of human form called Centaurus, who, wandering wild about the roots of Mt. Pelion, fell in with the Magnesian mares, from his association with which arose the semi-human race of centaurs. As to form, these beings were represented in sculpture as horses, perfect in all respects below and behind the withers and the chest; there, at the insertion of the neck, began a human body, the hip joints articulating into the shoulders of the lower animal, and the abdomen of the man uniting at the perinæum with the chest of the horse. Above this the human conformation was perfect, with the erect bearing, chest, shoulders, arms, neck, and head of a

medical powers, and said to cure not only fevers, but also the plague, and the worst ulcers, but is now in no repute among physicians.

CENTENARIUS, an officer in the armies of the middle ages who had the command of 100 men. Also, the person who conducted the administration of justice in a village.

CENTIARE, a French measure, the  $\frac{1}{100}$  part of an *are*, which see.

CENTIGRADE SCALE, or the CENTESIMAL, is the division into 100 parts, named grades or degrees, adopted particularly for the French thermometer. It was introduced in 1742 by Celsus, professor at Upsal, the limits of the division into  $100^{\circ}$  being the boiling and freezing points of water, though the scale was made to extend to convenient lengths below and above these points. In Fahrenheit's scale, the freezing point being  $32^{\circ}$  and the boiling point  $212^{\circ}$ ,  $180^{\circ}$  include the same range as  $100^{\circ}$  of the centigrade thermometer. The proportion of one degree of Fahrenheit to one of the centigrade is hence as 5 is to 9. But as the zero point of the Fahrenheit thermometer is  $32^{\circ}$  below the freezing point, which is the zero point of the centigrade, this number must be added to the results obtained as the correcting distance on

the 2 maxillæ and lower lip of may be regarded as maxillary tennæ are 2, varying greatly in length, and number of joints of vision are usually formed by simple eyes, but in some the compound eyes of insects, with All myriapods are wingless. In this class the number of the feet belonging to them, age; from the fact that without feet, Latreille : go a true metamorph states of *larva*, *pupa*, in them any more than ous insects. Latreille divides orders: 1. 2. 3.

the labium is quadrifid, and its 2 lateral a, the largest, are transversely ringed, emble the membranous feet of caterpillers have beside 2 palpi or little feet, at the base and unguiculated at the end, second labium formed by a second pair terminated by a strong movable hook at the end for the issue of an acrid

The body is membranous and flattened, being covered by a coriaceous plate, ring for the most part but one pair of a terminal segment being elongated into of tail; the sexual organs are interior, coed at the posterior extremity of the The centipedes move very rapidly in an ing manner; they can walk backward, the 4 hind legs, which in ordinary

n are dragged after them; they avoid, and are carnivorous in their habits; much dreaded by the inhabitants of imates, where they attain a large size, capable of inflicting dangerous wounds; d that their bite, though more painful

of the scorpion, is never fatal; the species of Europe (*lithobius forficatus*, very abundant under stones in the sun, is quite harmless, though repulsive

pect. The genus *scutigera* (Lam.) has ly covered with 8 plates, 15 pairs of d large reticulated eyes; they are noc- a their habits, and pierce their insect th their mouth-hooks, producing almost death; according to Illiger, they are

by the inhabitants of Hungary. The *olopendra* (Leach) has 21 pairs of legs, a the basal joints of the terminal legs are with spines; the segments are nearly of and number above and below. The

*uta* (Latr.) of southern Europe is almost as some of the species of tropical a. Several species of South America West Indies have doubtless been con- under the *S. morsitans* (Linn.), one of

rows to the length of a foot; very large also occur in Asia, Africa, and the archipelago. Ammonia is the best ap- a to their bites. Though among the gusting of living creatures, Humboldt his "Personal Narrative:" "I have seen children, of the tribe of the Ohaymas, t from the earth and eat millepedes or idræ, 18 inches long and 7 lines broad."

genus *cryptops*, Dr. Leach mentions 2 found in the vicinity of London; the very small, the antennæ are grained, basal joint of the more slender hind without spines. In the genus *geophilus*

the antennæ have only 14 joints, but vary in number from 42 to nearly ey are very slender, and some are phos- ent; they are destructive to fruit and les.—The position of the myriapoda can

be said to be determined. Siebold says not properly belong either to *arachnida* a, and he classes them under *crustacea*. Jones observes that they differ from

crustacea by their respiring air by means of tracheæ, and from annelids by their jointed legs, and that they seem to be an oeculant group, allied to annelids, insects, arachnida, and crustacea; they have urinary organs like insects, which crustacea have not. Prof. Agassiz makes them the lowest order of the class of insects, the other orders being arachnids and insects proper. Mr. Newport ("Annals and Magazine of Natural History," vol. xii., 1843, p. 228) traces the nervous system from the highest *chilognatha*, the most perfect of which are connected on the one hand with crustacea, and on the other with true insects, through the *geophili* (the lowest vermiform type of the *chilopoda*), to the tailed *arachnida* (the scorpions), and through *scolopendra*, *lithobius*, and *scutigera*, the last of which connects the myriapoda on the one hand with true insects, and on the other with arachnida. The heart, or dorsal vessel, as in insects and arachnida, is divided into several compartments, corresponding in number to the abdominal segments.

CENT JOURS, the second period of Napoleon's reign, so called because it lasted precisely 100 days, from March 20, 1815, when he reëntered Paris on his return from Elba, to June 28 of the same year, when the second restoration was established. (See BONAPARTE.)

CENTLIVRE, SUSANNA FREEMAN, an English dramatic authoress, born in Lincolnshire, in 1667, died in London, Dec. 1, 1728. Early an orphan, and maltreated by those to whom her education was confided, she fled from school while very young, intending to go to London. While travelling on foot it is related that she fell in with a Cambridge student, who persuaded her to accompany him to Cambridge, where she assumed masculine attire, and studied several months. To save her friend from suspicion she went from Cambridge to London, where nothing is known of her till at the age of 16 years she married a nephew of Sir Stephen Fox. Soon losing her first and also her second husband, who was named Carrol, she devoted herself to poetry, and produced a tragedy and several comedies. She also engaged as an actress, and while performing before the court at Windsor attracted the attention of a young man who was chief cook to Queen Anne, named Centlivre, to whom she was soon after married. From this time she lived in intimacy with Steele, Rowe, Farquhar, and other literary men, but incurred the enmity of Pope, by whom she was unjustly characterized in the first editions of the "Dunciad." Her comedies are esteemed for the ingenuity of the plots and the vivacity of the dialogue. The best of them are the "Busy-Body," the "Bold Stroke for a Wife," and the "Wonder, a Woman keeps a Secret."

CENTO (Lat. *cento*, patch-work), a poem composed wholly of verses taken from one or more poets, but disposed in a new order so as to form a distinct work. The only classical example is the *Cento Nuptialis* of Ansonius,

bolae).

**CENTRAL HEAT.** Since the year 1740, when the first observations respecting the increase of heat encountered with the increased depth below the surface were made by M. Genissanne in the lead mines of Geromagny on the upper Rhine, abundant data have been collected by scientific men in various parts of the world, establishing this as a general fact. The deepest mines of Mexico, England, France, Germany, and other countries, and the deeper artesian wells, and the hot springs ascending from still deeper sources, all lead to this conclusion. The volcanic fires add their testimony to the existence of intensely heated masses beneath the crust of the earth, and the vast extent of surface agitated when they are suppressed, and relieved by their outlet, seems to indicate an almost general diffusion of the liquid molten masses from which they spring. Not only is the heat found generally to increase with the depth, but the rate of this increase has in many instances been determined. It is found to vary in different countries, in some increasing 2 or 3 times more rapidly than in others. The average rate is estimated by Kupffer at  $1^{\circ}$  F. for every

globe ever passed from a liquid by radiation of heat, the central have begun to cool and consolidate the central portion fluid, tides ceived in the mass, sufficient to face to rise and fall every 6 hours. fluctuations are observed, even in that of Stromboli, which is supposed to connect with the great central mass. The phenomena that have given rise to this hypothesis combated by these perhaps require this theory to explain them. Local heat is without doubt generated by chemical changes taking place in the materials beneath the surface, which rise to electrical currents, of which to disturb the surface would be an idea, but judging from their limited scale on which they come under observation, it would seem quite as reasonable to refer to them the phenomena of volcanic outbreaks and earthquakes, as to aid so entirely hypothetical the molten fluidity of the central globe.

**CENTRE,** in general, a point

a central county of Pennsylvania; 1,000 sq. m.; pop. in 1850, 28,855. It is bounded by the Alleghany, Bald Eagle, and Susquehanna mountain ranges. It is drained by the Susquehanna, which supply several factories with water power. The principal occupation is agriculture and stock raising. The mountains are covered with valuable timber, but furnish little for cultivation. There are extensive iron, quarries of limestone, and coal in several places. The agricultural products in 1850 amounted to 438,000 bushels of wheat, 816,112 of corn, 186,204 of tons of hay, and 414,715 lbs. of pork. There were 48 churches, and 4,517 public schools. The county was organized in 1790, and named from its position, *intermedia*.

**CENTRIFUGAL FORCE.** The tendency of a body moving in a curved path to fly from the centre, has received the ill-chosen name of centrifugal force; ill-chosen, since it tends to fly from the centre, but continues moving in the direction it was at any particular moment. A stone in a sling flies off at right angles at the moment of its release. An *inertial* force is sometimes mentioned, the body is restrained from moving, and only allowed to slide on a surface. Inertial force, in this sense, is a mechanical power, of great practical operations as draining washed wool, and the oil from steel pens; since, the motion of such articles in a network of fibres can be communicated to the particles of fluid very far exceeding the distance, without injury to the fibre or solid articles.

**CENTRAL FORCE,** a central force of attraction, is a force tending, like that of gravity, to draw a body to a fixed centre.

**CENSUS,** in Roman antiquity, a college of judges, who decided civil cases, and presided to the rights of family and property. This court was instituted, according to tradition, as early as the time of Servius Tullius, as its number was ordinarily about 100. It was divided into 4 sections or colleges, each of 25 or the whole number of 100 might be pleaded. This tribunal of great importance under the empire, was entirely suppressed by Theodosius.

**CENTURIES OF MAGDEBURG,** a voluntary society of the church, and the first of the kind; so called from the arrangement adopted, which was to divide the world into centuries of 100 years each. It was first published in Basel, 1581, 8 vols. folio, bringing the history to the 14th century. The originator of the "Centuries" was Matthias Flacius, an opponent of the Interim, and so of

Melanchthon. The first 4 centuries were composed at Magdeburg (whence the name); the 5th, begun at Magdeburg, was finished at Jena; the 6th was written while the authors were sequestered from persecution; the 7th in Mecklenburg, and the remaining 6 in the city of Wismar. The publication was attended with much labor, from the comprehensiveness and complication of the plan. Of its execution Eickhorn, the celebrated German orientalist and theologian, speaks favorably. Each century is treated under 16 heads, viz.: general historical view, extent and propagation of the church, persecutions, doctrines, heresies, rites and ceremonies, government, schisms, councils, biographies, heretics, martyrs, miracles, condition of the Jews, other religions, political condition of the world. The authors are called *centuriatores*. A new edition by Baumgarten and Semler (Nuremberg, 6 vols. 4to., 1757-'65), brings down the work only to the year 500, and an abridgment by Oslander continues it to the 17th century (16 vols. 4to., Tübingen, 1807-'8). The principal writers, beside Flacius, were Wigand, Jodex, Faber, Corvinus, and Holzhauser.

**CENTURION,** an officer of the Roman army, in some respects corresponding to the rank of the modern captain. His command was the military division called a century, *centuria*, which corresponded with the civil division called a *curia*, so that the rank of *centurio* in the army was equivalent to that of *curio* in the state. It is supposed by Niebuhr, and other writers of the first authority, that the original century consisted of 30 men, and the great scholar first named is of opinion that the influence of the favored number, 80, can be traced throughout the whole of the ancient array of the Roman army. In later times the legion of heavy armed foot, *hastati, principes*, and *triarii*, without including the *velites*, or light-armed skirmishers, consisted of 80 maniples, each of which contained 2 centuries. In the time of Æmilius Paulus and Scipio, the strength of the legion when at its full war complement was 6,000 men, each century of course containing 100, each maniple 200, and each cohort—a later division of 3 maniples, variously attributed to Marius, Sylla, and Julius Caesar—600 men. The centurion who commanded the right century of the maniple, was styled properly *centurio*; he who commanded the left, *sub-centurio*, *optio*, or *uragus*.

**CENTURY,** in Roman antiquity, a company of 100 men, forming the 6th part of a cohort, and the 60th part of a legion. Servius Tullius carried this military division into the civil organization, and divided the Roman people into 6 classes according to property, which were subdivided into 195 centuries. To each of these centuries belonged a voice in the *comitia centuriata*; but as the first or most wealthy class of citizens comprised 98 of the centuries, it had a preponderance in the government. Each century was divided into 2 sections, that of the *seniores*, consisting of citizens from 45 to 60

70,481. The country is rugged and mountainous, particularly in the N. part, and the Black mountain, as the Mount Ænos of antiquity is now called, constitutes the most picturesque feature of Cephalonia. The climate is usually mild. The soil produces little corn, but some wine, oil, honey, and all the fruits of southern Europe. Currants, the staple product of the Ionian islands, come chiefly from Cephalonia. The blight of 1853-'55 has injured the crops materially, and reduced the exports from 40,000,000 to 11,000,000 lbs. The total value of currants received in the United States during the year ending June 30, 1856, was \$127,089, and in 1857, \$151,418. The large share which Cephalonia bears in the currant trade may be gathered from the fact that of 5,570,331 lbs. exported to England in 1855, 4,868,400 lbs. were from that island. The harbor is excellent, and ship building and various other branches of trade and industry are carried on actively. The imports consist mainly of breadstuffs and of the manufactures and wares of Europe. There are 11 public schools in the island, and 78 private schools. The Greek church is the predominant religion, and the inhabitants are chiefly Greeks. Property

may be properly given, since only as means of locomotion but hold upon any object. The animal is furnished with eyes and organs. The mouth, which is situated in the circle of feelers, is furnished with horny jaws, in shape resembling a parrot. The tongue is rough. Being aquatic, the cephalopoda possess gills. Most of this class possess resembling shells, though only the argonaut are entirely covered. Their arms are supplied with suckers they fasten themselves to and animals much larger and better than themselves. Even the firm crustaceans and crabs cannot defend themselves from their soft-limbed opponents by means of their suckers fasten to the shell, and with their strong beak pieces. To the class cephalopoda belong the nautilus, the argonaut, the known sepia or cuttle-fish. Several species, being entirely unprotected, are furnished with a bag containing a fluid. When attacked, the animal inflates the bag with air, and so increases the weight.

er he came with brilliant presents, and Procris did not withstand the subsequently diverted him from his discovery of their mutual weakness—a reconciliation between them. Procris slew his wife with his spear, taking her for a wild animal, and, jealously watching him in the morning, according to Ovid, Cephalus finally gave his name to the island.

**CEPHISSIA**, a village of Greece, 9 m. N. of Athens, with a grotto dedicated to the nymphs, much resorted to by devotees.

**CEPHISSIA**, or **MELAS** (anc. *Cephisus*), a river of Greece. It rises in Phocis, flows generally N., and forms the N. boundary of Boeotia; it is called the Copais.

**CEPHISSIA**, the name of several rivers in Greece. The most famous of them was the Cephissus, which flowed by Athens. The Cephissus, N. of the city, flowed southward, and crossed the long walls, and emptied into the Phaleric bay. Modern travellers describe it as winding its way through the country in several streamlets.

**CEPHISSIA**, GIUSEPPE, an Italian sculptor, born in Rome in 1760, died Feb. 1801. He took an active part in the disturbances of 1793, and was obliged to seek refuge in France. He there joined a band of republicans, who cherished a violent hatred against the monarchy, and at length made an attempt on the life of Louis XVI. The plot was formed in 1793, and the fatal deed was committed Oct. 11, at the opera. The conspirators were betrayed by one of their number, and Ceracchi with Diana and 4 others arrested, and a somewhat intricate trial, concluded with Diana executed.

**CERAM**, **SIRANG**, or **ZIRAM**, the name of the Molucca islands, in the Indian Ocean, lying N. of Amboyna, between the W. and Papua on the E.; lat. 8° 50' S.; long. 127° 51' to 131° 56'. The area is estimated at 10,500 sq. m.; pop. at 100,000. The topography is imperfectly known, but the general character of the surface is hilly, with mountain ranges, from 6,000 to 8,000 ft. high, covering the island, and giving rise to a number of streams which empty principally into the bay. The loftiest peak is that of Mount Kinabalu, 7,500 ft. above the sea. The climate is tropical, and the vegetation is luxuriant, and the spices and clove were produced spontaneously. It was first visited by the Dutch in the 17th century. The sago palm here reaches the height of 100 ft., and a single tree yields 1,200 pounds of starch. Many noble forest trees are found, but none suitable for ship building. The coast is fringed by a hardy, enterprising Malay population, chiefly by fishing, and find a market for the produce of their toil at Singapore and the other islands. Their vessels, called

*prahus* or *kora-kora*, are manned by from 30 to 60 rowers each. Most of these people are Mohammedans, but Christian missionaries have made many converts among them; and in one village of 620 souls, visited by Mr. Scherinus in 1846, the Christians numbered 438. The Horaforas, or Alfoories, who appear to be identical with the mountaineers of Celebes and the Philippines, are the dominant tribe of the interior. They are described as a brave, honest, and in most respects peaceable race of idolaters, among whom Christianity has made some conquests. A custom once prevalent among them of collecting human skulls for ornaments, to obtain which they would not hesitate to immolate a living victim, is apparently becoming obsolete. A little maize, for domestic consumption or exchange for dress, firearms, and fermented liquors, is cultivated chiefly by women; while the men are engaged in war or hunting. The Horaforas of Ceram have prominent features, large eyes, and long frizzled hair; they are brave, faithful, obedient, and make good soldiers. The other inhabitants are governed by several chiefs, who are subject to the Dutch residents at Amboyna and Banda. The native princes meet the Dutch residents once in 2 years, and have their disputes adjusted by a court of 24 rajahs, at which the resident presides. The population has been thinned by the internal dissensions of the Malays, the attacks of the Horaforas and of pirates, and the ravages of the small-pox. The Dutch claim the sovereignty of the island, and have established several forts on it. On the N. E. coast are the bay and village of Waroo, where good anchorage, water, and provisions may be had.

**CERASIN**, the gummy matter that remains, when the viscid exudation from the cherry, plum, and some other fruit trees is digested in water. The portion which dissolves is supposed to be the same substance as arabin. Cerasin is a tasteless substance, insoluble in water and alcohol, and unfermentable. It differs from bassorin in its being changed by the action of boiling water into arabin. The substance is applied to no use.—Also the name of a peculiar kind of wax which is found coating the sugar-cane.

**CERATE** (Lat. *ceratum*, from *cera*, wax), an ointment of stiff consistence, compounded of oil or spermaceti and wax, sometimes thickened with a powder.

**CERBERUS**, in Greek mythology, the monster that guarded the entrance to the infernal regions. He was a son of Typhon and Echidna, and is represented as a dog with many heads, the tail of a serpent, and a mane composed of the anterior extremities of numberless snakes. His business was to admit the spirits of the dead into their subterranean abode, but not to let them out again. Orpheus lulled him to sleep with his lyre, and Hercules dragged him from Hades, and exhibited him to the eyes of wondering mortals.

**CERCADO**, a province of Peru, in the de-

CERES, JEAN NICOLAS, a French botanist, born in the Isle of France in 1737, died there, May 2, 1810. Under the direction of the French government he greatly extended the culture of spices in the Isle of France (now Mauritius), when that island was a French dependency. The agricultural society of Paris published his essay on the culture of rice, and awarded him a medal; and Napoleon confirmed him in his position as director of the botanical garden of the Isle of France, and conferred on him a pension of \$120. A tree of the island has been called after him, *Cerea*.—HORTENSE, his youngest daughter, has translated several novels from English into French, and written a tragedy and sacred poetry.

CEREAL GRASSES, those grasses which produce the bread corns, as wheat, oats, barley, rice, rye, and maize; these having been called the gift of Ceres.

CEREALIA, a festival celebrated at Rome every April in honor of Ceres, if the citizens were not in mourning for some public calamity. If they were, its celebration was omitted, because no person wearing mourning could be present at it. On the occasion of this festival the wanderings of the goddess in search of her

the infant, and he perished in the attempt, and to make up for the loss, she bestows favors upon Triptolemus. the king of Eleusis. Ceres then came to Eleusis and appeared in her real character, informing the people of Eleusis, and ordering them to build her an altar and a temple. A temple was presently raised in the vicinity of Eleusis. the sorrowing Ceres took up her abode there. the mean time, the infant Persephone, her vine mother had visited her in the underworld, famine. Jupiter therefore ordered Hermes to entreat Ceres to suffer time to pass, and to bring forth her fruits, and to return to Olympus. He prevailed on her to return to Olympus. Ceres neither request would she condition that her daughter Persephone first restored to her. All the gods of Olympus were the same mission, but at length that it was a determination, sent Mercury to Pluto that he would return to the earth. The king of Hades refused the request, but while announcing that she was at liberty to

regions of darkness with your husband, other two-thirds you will be privileged on earth with me. The wrath of the was now appeased. She caused the yield her fruits in abundance as of instructed the Eleusinian sovereign nobles in the mysteries of her worship; when Jupiter sent Rhea to invite her once to Olympus, she cordially accepted the invitation, and went thither with her daughter to her abode again among the immortals. The chief seats of the worship of Ceres, at Rome, were Attica, Arcadia, and Sicily, where she was adored under the name of Demeter.

The principal sacrifices offered on her altars were swine, the symbols of fertility, oxen, honey, cakes, and fruits. Her image resembled that of Hera or Juno in its maternal character, but expressed more mildness and gentleness.

She was represented sometimes in a standing attitude, sometimes walking, and sometimes riding in a chariot drawn by horses or lions. Her attire was always complete, and on her head she generally wore a garland of flowers and a band of ribbon; while in her hand she held a sceptre, a bunch of corn, or a head of wheat, and occasionally a torch or mystic torch.

The principal festivals of the goddess were the Thesmophoria and Eleusinia in Greece, and the Cerealia at Rome.

**CÉRET**, a French town and arrondissement in the department of Pyrénées-Orientales. Population of the arrondissement in 1856, 42,181, and of the town, 3,488. The latter is surrounded by high tower-flanked walls, and is situated 6 m. from Perpignan, near the right bank of the river Tech, which is crossed by a high bridge—a bold structure of a single arch, and resting on two rocks. This bridge, a fountain of white marble, and a pleasant garden, are the only fine sights of the town, which is ill-built, with narrow and bad streets. Its chief industrial products are leather, and copper ware. The agricultural produce of the arrondissement is hardy, sufficient for local wants, but there are various manufactures, a good nail manufactory, and other industrial establishments. Céret was the place where the Spanish and French negotiators met, from March 22, 1659, to March 1, 1660, to fix the boundaries of the two kingdoms. The French were defeated here by the Spaniards, April 20, 1793; and on April 29 and 30 of the following year, Gen. Dugommier, with 10,000 men, carried the bridge and the adjacent gorges, which were defended by 10,000 Spaniards.

**CEREUS**, the name given to several species of cacti. The most beautiful of them is the flowering cereus (*cactus grandiflorus*), a native of parts of South America and the East India islands, and cultivated for its beautiful, sweet-scented flowers, which open in the evening and are quite before morning. The petals are white, and the calyx of golden yellow within, encir-

cling a vast number of recurved stamens, and opening to a diameter of nearly 1 foot. During the few hours of its existence the flower perfumes the air to a considerable distance and is of unrivalled beauty.

**CERIGNOLA**, a well-built and agreeably situated town of Naples, on a rising ground in the province of Capitanata, 24 m. S. E. of Foggia; pop. 10,500. The inhabitants are engaged principally in the cultivation of almonds and cotton, and also in linen manufactures. In 1503 (April 28) the Spaniards, commanded by Gonzalvo de Cordova, here defeated the French under the command of the duke of Nemours, who lost his life in the battle. In the principal street of Cerignola is a *milliarium*, recording that Trajan laid out the road from Beneventum to Brundisium at his own cost.

**CERIGO** (anc. *Cythera*), the southernmost of the Ionian islands, between lat. 36° 8' and 36° 22' N., and traversed nearly through its centre by the meridian of 23° E. long., at a distance of 150 m. from Zante, S. E. and at the entrance of the Laconian gulf. Its length from N. to S. is nearly 20 m., and its greatest breadth about 12. Area, 116 sq. m.; pop. in 1856, 11,868. The shores are abrupt and dangerous to shipping. Storms are frequent, the currents round the island being from its peculiar position very strong, and the air is rarely quite calm. The island is hilly, and abounds with streams. Although the soil is fertile in various parts, it has been little cultivated, but contains more pasture land and rears more cattle than any other Ionian island. Goats and sheep are also reared. Some corn and wine are raised, and about 7,000 cwt. of currants. The olive oil produced is of good quality, but limited in quantity. The most famous production of Cerigo is honey. The inhabitants still deserve the character of industry assigned by Heracles Ponticus to the people of Cythera, many of the peasants of Cerigo resorting annually to the Morea and to Asia Minor to work there during harvest time. Cerigo is the place of banishment of the criminals of the other Ionian islands, and no longer wears the charming aspect which once made it the favorite island of the goddess Venus. It presents, however, vestiges of its former splendor, and contains 2 curious natural caverns, which possess some stalactites of singular beauty. According to Pliny, the island was once called Porphyra. The ancient name of Cythera, however, is as old as Homer. Cerigo contains an English garrison, which is usually relieved every 6 months, has 2 towns and 29 villages, sends one member to the Ionian legislative assembly, and, together with Ithaca and Pasco, one to the senate. The chief town is Capsali, at the S. extremity of the island.—The principal dependency of Cerigo is a little island called *Cerigotto* by the Italians (anc. *Agilia*), now known as *Lrus* to the inhabitants, lying about 20 m. to the S. E., midway between Cerigo and Oreta, and containing about 40 families. Length, 5 m.; breadth,

man again, the Christ of Divine will drew. He attached no importance in the redemptive plan to the death of Jesus, but made salvation to depend on legal obedience. Caius, an anti-Montanistic writer, attempts to fasten upon Cerinthus the grossest and most sensual millenarianism, and even accuses him of having interpolated the Apocalypse to make it suit his chiliastic doctrines. It is true that Cerinthus taught the coming of a millennium on the earth, when Christ was to make Jerusalem the centre of his vast empire. This time he supposed would come after the earth had stood 6,000 years, and would be a perpetual sabbath of 1,000 years, a view which was common among the Jews of that age, and which has more or less perpetuated itself to the present day in Christian faith. His disciples were called Cerinthians, also Merinthians. A *Historia Cerinthi* was published by Paulus in Jena, in 1799.

OERITO, FRANCESCA, commonly called Fanny, a celebrated danseuse, born in Naples in 1823, is the daughter of an officer who served in the Neapolitan army under Murat. She made her debut at the San Carlo theatre in 1836, and, although only 13, was received with great enthusiasm. At Milan, in 1838, and for 2 years at the

late, or rural asylum, for the truant and vagrant children who, though demned as criminals, have shown penitence. This asylum owes its benevolence of a few gentlemen's neighborhood, who in 1847 formed raised a suitable foundation fund. A piece of wasteland were hired, where the society, on the payment of 100 per annum, was entitled to send a neglected child when the consent could be obtained. Secondary, religious instruction, agricultural was relied on as the great means of reformation, but as it was not a penal school, the system was carried out to a much less extent than at Mettray and other similar institutions. The number of children was limited in order that the personal and parental supervision of the director might be felt by each child. The director, M. Zweifel, was brought from the school of Fellenberg and Jacob. The boys are instructed for 2 hours in the morning, in the evening, in the various studies, and in the condition and wants. During the day, the children are engaged with their hands in every kind of work, and garden labour. By the

ance, which he is allowed to dispose of for his own benefit. Great pains are taken to avoid every thing like display or grandeur in the buildings, the apparatus or furniture of the establishment, or the dress of its inmates. The design is to fit and adapt the boys for an intelligent peasant life. The director, though a man of superior education and talent, had in 1858 a salary of only \$250 per annum. The results attained by this establishment have been most satisfactory. Of 41 boys who had been discharged in 1858, and apprenticed or placed with small farmers, only 2 had turned out ill, and one of these was a young man admitted at the age of 16, whose vicious habits were too firmly established to be readily eradicated.

CERRETO, a well-built town of Naples, province of Terra di Lavoro, on the Apennines, 21 m. N. W. of Benevento; pop. 5,600. It has a cathedral, a collegiate church, and a diocesan school, 5 annual fairs, and cloth manufactories. It occupies the site of the Cernetum of the Romans, near which Pyrrhus was defeated, 275 B. C.

CERRO GORDO, a mountain pass in Mexico, on the national highway between Vera Cruz and the city of Mexico, rendered famous by the victory gained by the American forces, under Gen. Scott, over the Mexicans under Santa Anna, April 18, 1847. The *calzada*, or paved portion of the national road to the city of Mexico, extends from Vera Cruz N. to the city of Jalapa, some 70 m., crossing, half way, the stone bridge called *punte nacional*, and is carried through the defile of Cerro Gordo, at an elevation of 4,264 feet above the sea-level. Fifty miles from Vera Cruz a small plain stretches out, called the Plan del Rio. From this plain the road gradually ascends a distance of 4 m. through winding defiles, till it reaches the gorge of the Cerro Gordo (big hill), a conical hill, which rears its summit 1,000 feet over the adjacent ascents. On the right, the road is alternately shut in by cliffs and chaparral, or thick brush, and on the left by precipitous walls of rock. Gen. Scott describes the locality as "a field of operations covering many miles, broken by mountains and deep chasms." It was along this road that the Americans, flushed with the recent capture of Vera Cruz and the castle of San Juan de Ulloa, were pushing onward to attack the enemy's capital. Scott was encamped on the Plan del Rio when word was brought him that the Mexican general, with a force equal to or exceeding his own, had fortified the pass of Cerro Gordo, and was determined to dispute the passage. The whole American force present in action and reserved was 8,500; the Mexican was estimated at 12,000 or more. Gen. Scott acted without hesitation. Making a careful reconnoissance, he found that the enemy had fortified himself on the ridge at the left of the pass, and on the hill itself, and had, beside, established 2 batteries across the road, one at the throat of the pass, near the base of

the hill, and the other further on the road toward Jalapa; his defences on the heights being a series of breastworks covering each other, as well as commanding the road; the slope in front of his guns broken by ditches and brush to obstruct the advance of stormers; the extreme left of his position covered by the river flowing at the base of the ridge, his right being guarded by thick chaparral toward Jalapa, with which city his communication was open. In general terms, he held a fortified position, extending in a semicircle of 2 m. on the slope of a mountain defile, at the base of which lay the only road by which the Americans could advance, and which road was enfiladed by batteries. A tower near the summit of the hill, defended by 8 guns, commanded the whole of his works, and was, in effect, the key of his position. Neither the strength nor the weakness of this disposition escaped the American commander. In the forenoon of the 17th he ordered Gen. Twiggs to occupy a certain ridge on the right of the road. The American column, advancing boldly, drove in the outposts and took possession of the first ridge. The Mexicans, being reinforced, took possession of a second slope within range of the batteries on Cerro Gordo, and made a stout resistance, but were speedily dislodged, and driven at the point of the bayonet completely over the hill, a party of Americans boldly pursuing them to the edge of their lines. During the night the Americans managed, with incredible labor, by the aid of 500 men to each gun, to drag up to the summit of the hill 1 heavy 24-pounder, and 2 24-lb. howitzers. The appearance of this battery on the morning of the 18th greatly astonished the Mexicans. An 8-inch howitzer was also placed opposite the enemy's right battery. These preliminary operations being completed, Scott, on the evening of the 17th, drew up the programme of battle. This document is a model of perspicuity. Its substance is as follows: The enemy's whole line of intrenchments and batteries will be attacked in front, and at the same time turned, early in the day, to-morrow—probably before 10 o'clock A. M. Twiggs's 2d division of regulars will move forward before daylight, and take up position across the national road to the enemy's rear, so as to cut off retreat toward Jalapa. Twiggs may, or may not, be reinforced by 1 or 2 volunteer regiments, as circumstances shall determine. Worth's 1st division of regulars will follow the movement against the enemy's right at sunrise to-morrow morning. Pillow's brigade will march at 6 o'clock A. M., along the route already reconnoitred, and stand ready, as soon as he hears the firing on the right (sooner, if circumstances favor), to pierce the enemy's line of batteries as near the river as he may select. Once in rear of the batteries, he will turn to the right or left, or both, and attack them in reverse; when the enemy abandons the batteries he will pursue with vigor, until further orders. Wall's field battery and the cavalry will be held in

Jalapa road. Pillow divided his command into 2 parties, under Col. Haskell supported by Col. Campbell, and Col. Wynkoop supported by Col. Roberts, who were simultaneously to storm the batteries on their left. Every thing was carried out in accordance with the general's orders. At daybreak Shields and Riley, with their brigades, Capt. Lee, of the engineers, acting as their guide, set out over a tract almost impassable, to reach the Jalapa road, and turn the enemy's flank. By the time they reached the Jalapa road the battle was raging in front, and a considerable body of Mexicans, among them Santa Anna himself, had already withdrawn to this point, with the view to secure a retreat. As Shields gained the road, a masked battery opened fire. He had barely time to give his men orders to charge and take it, which they gallantly did, when he fell, shot, but not mortally, through the lungs. The battle in front commenced by the Mexicans opening a plunging fire on the battery established by the Americans during the preceding night. Firing became general along the line. Twiggs, thinking it time to attempt the heights, confided to Harney a detachment consisting of a portion of the 1st artillery under Col. Childs and infantry

rendered at discretion. A large enemy, estimated at 7,000 or 8,000, Santa Anna, who had reached Jalapa before the division sent to intercept him, fled in flight toward Jalapa, pursued by Shields and Twiggs. The programme had been carried out in all respects before 2 o'clock. The spoils of the victory were 3,000 prisoners, 5,000 stand of arms, 43 pieces of artillery, 7 standards, together with Santa Anna's baggage and money chest. Five officers among the captured, namely, Pizarro, La Vega, Noreiga, and Obando; and 100 men, having been killed. The enemy's loss computed at from 1,000 to 1,200. Our own loss in the two days amounted to 10 officers and 398 men, in all 408. Among the killed were Lieuts. Ewell, Nelson, Gill, and Yearwood, of the 1st regiment, were killed. Capt. MacFarland, of the 1st regiment, subsequently died of his wounds. Gen. Patterson, who was sick, left the army, sharing in the fortunes of the day. The general, deeming it inadvisable to be encumbered with baggage and prisoners, ordered the baggage and prisoners to be sent to the rear, leaving the army to move on.

(Mexican) position was well chosen, it was fortified as well as circumstances permitted; its flanks were well covered, and all was foreseen that might be foreseen, in regular order, and in the tactical tactics of war. True it is, that no expectation was entertained of the rare, bold, and desperate operations of the enemy, who, in the night between the 17th and 18th, broke through the woods, crossed a ravine, up to that time never crossed, and taking in reverse the position which the main body of our army occupied, surprised it in the time of action, made a general attack on all parts at once, and cut off the rear of the infantry, artillery, and even part of the cavalry." The writer then asserts that

Anna *did* cover the rear of the position, notwithstanding the old opinion, confirmed by the experience of the whole war from 1810 to 1821, that the road by which the enemy attacked us was impracticable." That movement he likens to the passage of Bonaparte over the

The affair of Cerro Gordo made a great impression throughout Mexico. Five months afterward the American flag floated over the Mexican capital.

CERRO GORDO, a N. co. of Iowa, formed in 1850, of a wild and thinly settled part of the state, named after the above-described mountain; area, 652 sq. m.; pop. in 1856, 632. It is drained by Lime creek and its tributaries. Its productions in 1856 were 1,025 tons of wheat, 936 bushels of wheat, 1,135 of oats, 11,795 of Indian corn, 8,845 of potatoes, and 5,589 lbs. of butter.

CERTIORARI (Lat. *certus fieri*, to be made certain, to be certified), a writ used for the purpose of removing the record in a particular case, whether civil or criminal, from an inferior to a superior tribunal, either as an auxiliary process to obtain a full return, or as some other process, or as a distinct mode of appeal. In American practice it is usually employed to review the proceedings of courts not of record, and of municipal corporations in certain cases, and the determinations of special tribunals, commissioners, and other officers exercising judicial powers which affect the citizen in his rights or his property, and acting in a summary way, in a course different from that of the common law.

CERUSE (Lat. *cerussa*), a name given to the white carbonate of lead, the basis of the white paint. (See WHITE LEAD.)

CERVANTES SAAVEDRA, MIGUEL DE, the author of "Don Quixote," born at Alcalá de Henares, Spain, Oct. 1547, died April 23, 1616, on the same day with Shakespeare. His father was descended from an ancient Galician family, and his mother, Leonora de Cortinas, was a gentlewoman of refinement. Cervantes received the first rudiments of education from a brother of his father, Juan de Hoyos, who occasionally published collections of poetry, to which his pupil, who early displayed a talent for poetical composition, contributed *Filena*, a pastoral poem,

and other compositions. *Filena* obtained some reputation, and attracted the attention of Cardinal Acquaviva, who, in 1569, invited the young poet to accompany him to Rome. But the stately monotony of ecclesiastical life was little calculated to please the ardent nature of Cervantes, and yearning for more stirring spheres of action, he joined in 1571 the Christian armament, commanded by Don John of Austria, against the Turks. In the great battle of Lepanto (Oct. 7, 1571), he received a wound, which deprived him of the use of his left hand and arm for the rest of his life; but his enthusiasm rose above all physical sufferings, and he remained in active service until 1575, when, on his way from Italy to Spain, the galley in which he sailed was captured by Algerine corsairs. He was in their power until 1580, when his relatives and friends purchased his freedom. The whole romantic account of his captivity is found in his novel, "The Captive." He was treated with great cruelty by the Moors, but his cheerfulness and philosophy seemed to increase in proportion to the severity of his trials, and excited the admiration of his fellow-prisoners. He returned to Madrid in his 34th year, covered with a prestige of glory, romance, and adventure, and here his literary career properly begins. The first work which he now produced was the pastoral romance *Galatea*, said to have been written in honor of his mistress, which showed a decided progress upon his *Filena*, and by its command of language and richness of thought, at least, raised the expectations of his friends. In 1584 he married an accomplished young lady of Esquivias, and now had more than ever to resort to his pen to supply the wants of his family, and for 8 years he wrote plays for the stage, which, however, brought him little fame and still less money. In 1588 he removed from Madrid to Seville, where he acted as an agent of a royal commissioner of the American fleet, and afterward as a collector of public and private debts. During the latter part of 1597, he was imprisoned for about 8 months at Seville, for a small sum due to the government. From 1598, when he seems to have left Seville, until the beginning of 1608, when we find him established at Valladolid, we lose all trace of him. He is said to have spent the interval in La Mancha, and to have been sent there to collect rents due to a monastery; but the debtors, instead of making payment, persecuted him and threw him into prison. Here he is said to have begun to write his "Don Quixote," laying the scene of the knight's earlier adventures in La Mancha, and making him a native of the village that treated him so ill. But no direct proof exists in support of this statement, although it is certain that he spent some time in La Mancha.—We now come to the great literary performance of Cervantes. It must here be borne in mind that the death of Philip II. took place in 1598, and the relief which the end of his despotic rule brought to Spain was

felt also in the world of letters. Cervantes could now give free vent to his opinions; and the general tenor of his life, as well as the influences of the age, enabled him to perform the task with remarkable success. His occupation at Seville and La Mancha had given him new opportunities of observation. In his youth at Rome, he had observed in Cardinal Acquaviva's house the character of high life, and there, and subsequently in Spain, he was constantly brought in contact with persons eminent in church, state, and literature. With the camp and Moorish life he was thoroughly familiar, from his service in the navy and his captivity in Algiers. The mysteries of the stage, the characteristics of actors, were known to him from his career as dramatist. His frequent journeys had brought him into close contact with persons of all classes. With such a world of experience, with an inexhaustible stock of humor in his disposition, and with a love of the ideal and the heroic in his heart, this laughing philosopher, acute observer, and at the same time classic and polished writer, produced, in the full maturity of his genius, after having passed the 50th year of his age, his imperishable "Don Quixote." The first part was published at Madrid in 1605. In this work Cervantes hit the vulnerable point of his age. The common sense of the world had long rebelled against the mummeries of knight-errantry, and the foolish books that still spoke of a chivalry of which, in reality, not a vestige remained. People who had smiled when the absurdity presented itself to their minds, burst out in laughter when Cervantes gave it the finishing stroke. The laughter became universal, and it is still going on, constituting a perennial source of pleasure, blended with a tender sympathy for Don Quixote, whose sublime intentions we are bound to admire, while his ridiculous actions are a perpetual entertainment. Grave moralists may object to the general hilarity, and argue that to ridicule performances which, after all, resulted from an exalted sentiment of heroism, self-sacrifice, and unselfishness, is ridiculing goodness itself. But philosophers might as well attempt to stop the fall of the waters of Niagara, upon the ground of the impropriety in the noise of the cataract. Mankind began to be tired of the hypocrisy, sentimentality, sensuality, and folly of the books of chivalry. A new world had been discovered by Columbus. A new interpretation of Christianity had been set forth by Luther. Dante, Petrarch, Ariosto, and Tasso had published their immortal poems. The reign of Elizabeth had given an impetus to English progress. The advent of Shakespeare had taken place. Philip II., the enemy of the new, and the champion of the old systems, had just gone to his grave. Even old Spain yearned for some free-spoken word which would end the weary spectacle of an effete literature. Cervantes uttered that word. Its name was Don Quixote. One day Philip III.

observed from the opposite banks of the river, laughing over a book. "crazy," said the king, "or he the history of Don Quixote." in 1606, after the court had moved from Valladolid to the capital. Cervantes published the first part of the book during his residence at Valladolid, where, on his return from Seville and La Mancha, he set up his residence, as he alleged, for business. Although he received frequent patronage from persons connected with the literary world, he was not married; his wife, his 2 sisters, and a female domestic, on the one hand, and a comfortable looking house, and his literary efforts, on the other, were great. In 1605, while the publication of "Don Quixote," and its success (30,000 copies being sold on the first day, and translations soon appeared in all foreign languages), drew attention to Cervantes and the active heroism of his satire, he occupied himself with the publication of *Exemplary Novels*, written many years before, and which had already given him the reputation of the "Curious Impertinent." In 1614 he published *Parnaso*, a satirical work on the state of Spain at that time, in which he described the bitterness, as the chronicler of the state of Spain, naked Adam of Spanish poetry. In the same year, while he was preparing the 2d part of "Don Quixote," he published a bungling plagiarist of the name of Avellanada. The invectives against Cervantes published at the same time. The 2d part of "Don Quixote" appeared in the beginning of 1615, written to the conde de Lemos, expressive of the kindnesses extended to him by the king at the same time full of It was received with the demonstrations of enthusiasm which marked the 1st part. Cervantes had at the height of his ambition. He had no other rope, while even in Spain, as large as life, there was no one to divide the literary empire. The sale of the "Lazarillo" also relieved his pecuniary straits. But his health, and a presentiment of the future, indicated in the *Novelas y Sigismunda*, a work published after the "The Heliogabalus," which was published at the beginning of 1616, until after his death. On April 19, he uttered the following words:

to whom he dedicated the work, and show that to the last the qualities of soldier, poet, and philosopher were adly combined in his generous and genial : "I have my feet already in the stirrup.

use this expression since I feel that with ot I stand in the grave. Yesterday I re- l extreme unction; to-day I resume my

lid editions of Don Quixote are those appeared in 1780 at Madrid, in 4 vols., t Paris in 1827, (Didot, 18mo.) One of

st is the Madrid academy's 4th edition, ed in 5 vols. in 1819, with a bio- cal sketch of Cervantes by Navarrete.

Spanish biographers are Mayons y Ciscar ellicer. The edition of 1833-'39, in 6 vols., very complete commentary by Diego Cle-

n. The pocket edition of Leipsic, 6 vols., '7, also deserves notice. His complete y, excepting his comedies, appeared at

d in 16 vols., 1803-'5, and also another n in 1811, which, however, does not in- his *Viage al Parnaso*. Arrieta, of Paris,

hed in 1826-'32 a selection of his works, vols. Baudry's edition, published at Paris 40-'41, gives his complete works. Ros-

coe's "Life and Writings of Cervantes" ap- peared in London in 1839. The most emi- nent German translators of "Don Quixote" are Tieck, Bertuch, and Soltan. The best Eng- lish version is that of Motteux, with notes and additions by Lockhart.

OERVETRI (the *Agylla* of the Pelasgi, and the *Cære* of the Etruscans), a village of Italy, in the Pontifical States, Comarca di Roma. Cære was one of the 12 great cities of the Etrurian confederation, and is celebrated by Virgil as the capital of Mezentius. Some re- mains of its walls and tombs are still seen in the neighborhood of Cervetri, which occupies the site of the acropolis of the ancient city. It has a deserted palace of the Ruspoli family, on whose eldest son it confers the title of prince of Cervetri. The most remarkable of the tombs recently discovered is that of the Tarquina, found in 1846, containing 2 chambers, one of which is called by the peasantry the *Grotta delle Iscri- sioni*, from the number of its inscriptions.

OERVIA, a town on the Adriatic, in the Pontifical States, legation of Forli; pop. about 4,000. It is situated in the vicinity of marshes which contain the most important salt works in the country.

OERVIN, MONT (It. *Monte Silvio*; Ger. *Matterhorn*), a mountain of the Pennine Alps, between the Valais in Switzerland and the Val d'Aosta in Piedmont, celebrated for its matchless picturesqueness and beauty; eleva- tion about 15,000 feet. At a height of about 11,000 feet is the famous pass of Mont Cervin (Fr. *St. Théodule*; Ger. *Matterjoch*), traversed in summer by mules and horses. Prof. Forbes describes Mont Cervin as the most striking ob- ject he had seen, "an inaccessible obelisk of rock, not 1,000 feet lower than Mont Blanc."

OESARE, GIUSEPPE, cavaliere di, an Italian historian, born in 1783, in Naples, died there April 15, 1856. He was at the head of the custom-house of his native city until 1827, when he was dismissed for political reasons. When the constitutional party came into power in 1848, he was appointed governor of the prov- ince of Bari, but tendered his resignation as soon as absolutism was again triumphant. He subsequently devoted himself to literary labors, and wrote *Arrigo di Abbate* and *Lettere Romane*, historical novels. But his most im- portant production is his *Storia di Manfredi, re di Sicilia e di Puglia*, which appeared in 1837, and obtained a wide popularity, not only on account of its literary merits, but also in consequence of the efforts of the author to clear Manfred's memory from the imputations of previous writers. For several years he edited a periodical entitled *Il Progresso*; and in Man- cini's *Biblioteca di scienze morali, legislative, ed economiche*, he published an able paper on the philosophy of history. He is also the author of a history of the Lombard league.

OESAROTTI, MELCHIORE, an Italian poet, born in Padua, May 15, 1780, died Nov. 1808. He officiated as professor in the university of

cathedral, but spent his vacations at Ceve, where he established a museum of ancient art. Cespedes was one of the best colorists in Spain, and a successful imitator of Correggio. He was an accomplished scholar in ancient and modern languages, and left a poem on painting and some essays on art. He had a considerable reputation also as a sculptor and architect.

CESSION, an English law term importing the avoidance of a benefice or preferment by the acceptance of a second which may not be held with the first. The incumbent, however, may be relieved by dispensation from the operation of the rule.—In politics, cession is the yielding up of territory to another power. The knights of Malta ceded their island to the French when Bonaparte requested them to do so. French colonies have been ceded to the English at various times.

CESTUS (Gr. *κεστος*, stitched), a band or tie of any kind, particularly applied to the embroidered zone or girdle of Venus, famed for its power of awakening love. By this, according to Homer, Venus captivated Mars, and Juno borrowed it in order to win the affections of Jupiter. The bridal girdle, which was worn by the bride, and unloosed by the husband after

duced by the mixture of French wine and brandy. The total annual wine comprise about 40,000 caddy, 5,000. The salt-works in the are the most important in the yield annually above 500,000 cwt. The fisheries of sardines (which are of cod, and oysters, employ about There are also glass-works, 4 building yards, and an establishment of sulphates of soda, and ash by evaporation from sea-water soap, sirups, grape sugar, and there. The town possesses a market, various courts of justice, a hydrographic school, a cabinet library, a theatre, and a public bathing. It was laid out in 17 designs, at a great cost, and the labor were executed by M. Riquet. the *canal du Midi*. In 1710 a fleet of Commodore effect a junction with the innennes, took possession of the back after a few days. embarked here for CETTI. GIOVANNI

about 5 hours' journey from the Austrian town of Cattaro, is a mountain village, with about 20 well-built houses. It is, however, the only fortified locality in the country, has a fort which resembles a castle, a school since 1812, and on a plain below the village is a new government house, where the public affairs of the province are conducted, and where the prince of Montenegro resides. Gunpowder is manufactured here, and some trade is carried on with Dalmatia. **CETUS**, the whale, a large constellation of the S. hemisphere containing 97 stars, and said to represent the monster which was going to devour Andromeda. Its brightest star, named *Alkaid*, comes on the meridian at 8 o'clock at the beginning of January.

**CEUTA**, or **SEBTA**, the Botany Bay of Spain, a town and fortress, forming part of the province of Cadiz, situated on the N. coast of Fez, the empire of Morocco, at the E. entrance of the strait of Gibraltar, where a small peninsula juts out in a N. N. E. direction exactly opposite Gibraltar, being joined to the mainland of Africa by a narrow but well fortified isthmus, which the town is built. The N. E. of the town is almost entirely occupied by the Monte Hacho (the anc. *Abyla*), which is a spur of a range of mountains called Jebel Zatout (anc. *Frates*).

On the highest part of the mountain stands the citadel of Ceuta. The garrison consists of 5,000 men, and the population, which has singularly diminished during the last years, was not above 2,122 in 1852. The town is well built, gives title to a bishop, who is suffragan of the archbishop of Seville, and is the seat of a royal court of justice, and the chief of the Spanish presidios or convict establishments on the African coast. The others, comprising in all an area of 82 sq. m., and a convict population of about 11,000, are under the charge of the governor of Ceuta. The town is clean and paved in a mosaic pattern, has a cathedral, several convents, and a house of mercy founded in 1498, but little trade, the unsafe harbor militating against commercial activity.—Ceuta was a town of Mauritania Tingitana, under the Romans. In 1415 John I., king of Portugal, wrested it from the Moors, who in their invasions of Spain first set out from Ceuta. In 1580 it passed with Portugal to Philip II. of Spain by conquest, and was formally ceded by Portugal to Spain by the treaty of Lisbon of 1668. Afterward it was unusually besieged by troops from Morocco. At the beginning of this century it was held for a short time by the English.

**CEVA** (anc. *Ceba*), a Piedmontese town, at the confluence of the Cevetta with the Tanaro, in the province and 10 m. E. of Mondovì; pop. about 4,500. It has a church and 8 convents, and the chief feature of the town is a rock on which are the remains of a citadel formerly used as a state prison. The inhabitants are employed chiefly in cultivating the vine, in manufacturing silk, and in iron works. The celebrated Piedmontese cheese, called

*Robiola*, is made here, and was renowned even under the Romans, and praised by Pliny. Coals are found in the neighborhood, and truffles abound. It was formerly the capital of the marquisate of Ceva, and was several times besieged and conquered by the French and Spaniards. It was taken by the Piedmontese in 1796, and successfully resisted an attack of the French in 1799. Its principal fortifications were destroyed in 1800, and have not been rebuilt.

**OEVA**, **TOMMASO**, an Italian mathematician and poet, born Dec. 20, 1648, in Milan, died Feb. 8, 1786. He was admitted into the order of Jesuits in 1663, and spent his life as an instructor in various colleges. His more important mathematical works had reference to angles, for the trisection of which he invented a mechanical instrument. He wrote several biographies in Italian, and many poems in Latin and Italian, 2 of which, entitled *Philosophia nova-antiqua* and *Puer Jesus*, are still admired.

**OEVALLOS**, **PEDRO**, a Spanish diplomatist, born in 1764 at Santander, died about 1838 at Bayonne. In the difficulties between Charles IV. and Ferdinand he joined the latter, and accompanied him to Bayonne, where he was eyewitness of the various intrigues which ended in the occupation of Spain by the French. Joseph invited him to Madrid; he accepted the invitation, but soon declared against the French, and went to London to forward the interests of the junta. In 1808 he published a celebrated paper on Spanish affairs, especially on the proceedings in Bayonne, which contributed powerfully to excite the public mind against Napoleon's aggressive policy. He took an active part in the civil service of the liberal cause during the war of independence, and, on the restoration of Ferdinand, officiated for a while as his secretary of state; but losing this office by opposing Ferdinand's marriage to a Portuguese princess, he was sent as ambassador to Naples, and afterward to Vienna, and in 1820 was entirely discarded by the government and obliged to retire into private life.

**CÉVENNES**, a mountain range of France, beginning at the canal of Languedoc, running N. E. to near the central canal, and separating the basins of the Garonne and the Loire from those of the Saône and the Rhône. It extends over nearly 400 m., and is divided into the S. and N. Cévennes. The former, which contain extinct volcanoes, assume successively the names of Black, Espinouse, Garrigues, and Lozère mountains, and form the group of Gévaudan, several branches of which diverge in various directions; the most important, running N., connects with the cluster of mountains of volcanic origin known as the mountains of Auvergne. The highest points of the Cévennes are Mount Mézin, 5,918 feet, and Mount Lozère, 4,870 feet. The N. are of less importance, and are scarcely more than hills, under the names of Vivarais, Lyonnais, Forez, and Charolais mountains. They connect with the Vosges, through the hills of Côte d'Or, the plateau of Langres, and the Fan-

gulf of Manaar, together with the holy island of Ramisseram, nearly connect it with the mainland. From its position and geological character, Ceylon indeed appears to have been once part of the mainland. The straits which now divide the two are navigable only for small vessels. The one nearest the Malabar coast has been widened and deepened by the British government, and is now passed by vessels of 300 tons, thus much facilitating the coasting trade, and materially shortening the voyages between the Malabar and Coromandel coasts. The W. and S. coasts are low, much indented, and lined with cocoanut and other palms. Numerous small harbors are found along this shore. The E. coast, from Point de Galle to Trincomalee, is an arid but bold and precipitous shore. On these sides the line of coast is of varying depth, from 30 to 80 m., surrounding the mountain ranges which form the centre of the island. The northern shore, from Calpentyne to Batticaloa, is a vast arid and sandy plain, teeming with swamps and jungle. It is on this coast that the pearl oyster banks are found; and on occasions when the fisheries are opened, vast but temporary towns are suddenly formed.

summit on the island. It is by Mohammedan and Buddhist one of their holy places. They firmly believed, among others, leaving Paradise, rested with one, and with the other upon Ramisseram, using the bowlders of the Manaar passage as stepping stones from the island to the mainland. The summit of the peak, very difficult and attained by a series of steep ascents, is a rock, on which is the image of a vast human foot, 5½ feet by 4½ feet. This impress is carefully guarded by priests, and protected from the elements. The name of the mountain is the Cingalese name Adam's Peak. It is in lat. 7° N., and long. 81° E. S. E. of Colombo.—The island is watered by numerous small rivers and brooks, but few streams. Few are navigable more than a few miles from their mouths. Mahavilly Gunga, which is 20 miles long, next, the Kalani Gunga, has its source at the foot of Adam's peak, and falls into the sea near Colombo. There are no lakes in the interior, but several extensive

a wall of masonry 12 m. long and 160 feet thick. These collections of water were formed by damming the natural outlets of the mountain streams at the mouths of extensive valleys. They were of great service to the country when more densely populated and thoroughly cultivated than now.—A belt of gray and black sandstone and coral formations nearly encompasses the island. The rocks of the interior are mostly primitive, consisting of granite, gneiss, large veins of quartz, &c. Limestone occurs only in Jaffnapatam and the northern districts. The surface soil is mostly sandy. The cinnamon soil near Colombo is perfectly white, and consists of pure quartz. Ores of iron, lead, tin, and manganese are found in the interior. Plumbago is found of excellent quality, and is a considerable article of export. Quicksilver mines exist, and were formerly worked by the Dutch. Various gems are found, and salt beds are worked to advantage. The most valuable gems are the ruby, sapphire, amethyst, cat's-eye, and carbuncle. Cinnamon stones and garnets exist in great plenty. The plumbago mines, of which there are 14, are worked by natives. The mineral is obtained at depths of from 3 to 30 feet, and in rich seams. In 1851 the exports of plumbago amounted to 81,136 cwt., valued at \$28,000. Iron ore is worked up by the Cingalese in a rude way, but with considerable success, the iron being equal in temper to the best Swedish. Salt is a monopoly of the government.—The climate of Ceylon differs little from that of the neighboring part of India. The island is, however, much healthier than any portion of southern India. The N. E. and S. W. monsoons mark the changes of the seasons. The changes, which occur on the sea-coasts in May or June and October or November, bring with them heavy thunder storms. The highest temperature at Colombo is about 87°; on the coffee estates it is stated at between 56° and 80°; and in the high valley of Newera Ellia, during January and February, the mercury falls as low as 31°. The prevailing diseases of the country are cholera, dysentery, and fevers. Elephantiasis is a disease peculiar to the natives. The beri-beri (*hydrops asthmaticus*) is another disease nearly peculiar to the island.—The zoology of Ceylon is much the same as that of the adjoining mainland. The elephant, which stands at the head of the animal list, is of a less tractable or useful species than those of India and Africa. They exist in great numbers in the interior, and commit numerous ravages upon the native fields. They are frequently trapped in vast kraals, into which they are driven by a great assemblage of natives. Of late years, English hunters have killed great numbers of them for sport and for their tusks. Oxen of small size and buffaloes are used as draught animals. There are 4 species of deer, and a species of the Indian musk, a great variety of monkeys, as well as the hare, squirrel, porcupine, wild boar, bear, and one species of ant-eater. Of birds there

are all the varieties common to the tropics. The *hirundo esculenta* is stated to build its nests on the coast; but the nests do not form an article of commerce. There are several varieties of serpents, one of which grows to the length of between 20 and 30 feet. Crocodiles are found in the rivers, scorpions and huge spiders in the houses, and a flying lizard in the woods. Fish are of numerous varieties, and in great abundance, some of excellent quality for eating.—The vegetable products are both numerous and valuable. There are 416 varieties known of valuable woods, of which 33 are used for house, furniture, and ship building. Among these is the satinwood and ebony. The upas tree has been found in the interior. The cocoanut palm is altogether the most useful tree to the natives. It grows readily without cultivation, is not limited to one soil, and every part of it is made use of by the Cingalese owner. The fruit, when green, supplies food and drink; when dry, oil; the sap is made into toddy and arrack; the fibrous husk makes ropes, nets, and matting; the nutshells form household utensils; the plaited leaves serve the same purpose, and also furnish thatch for the cottage; the dried flower-stalks serve as torches, and the large leaves as garden fences. The trees bear from 50 to 100 nuts per annum, and grow so near the water's edge that the waves wash their roots. There are several other varieties of palms, one of which furnishes, in its wide-spreading leaves, the umbrella, which is a notable article of Cingalese use. The fruit of the betel palm is exported to the amount of \$60,000 per annum. Beside native fruits, which are not numerous, various European and Indian fruits have been introduced latterly under the auspices of English planters, who have formed an agricultural society. Cinnamon, which grows wild in the forests, is cultivated to a large extent, arrives at a high state of perfection, and has long been a chief article of export. Its cultivation was formerly a government monopoly, but was thrown open to the public in 1883; cultivators paid, however, for many years, 8s. per lb. export duty; this is now abolished. When growing wild, the cinnamon plant attains a height of 20 to 30 feet; cultivated, it is not allowed to grow so thriftily, the young shoots giving the finest bark. Coffee flourishes as readily as cinnamon, and its cultivation has in many places taken the place of the latter. Rice, cotton, tobacco, pepper, &c., are also cultivated. Bread-fruit flourishes to a remarkable degree. The sugar-cane does not succeed. There are 2 rice harvests annually, Jan. to March and Aug. to Oct.—Ceylon was known to the Greeks and Romans under the name of Taprobane. Pliny relates that Onesicritus, a captain of Alexander the Great, first circumnavigated it, and thus discovered it to be an island. Before this it was supposed to stretch indefinitely south. The Cingalese have a legend that the island was once much larger than at present; and this seems to receive confirmation in the fact recorded by a Roman

the 17th century, and in 1681 published an interesting account of his 20 years' captivity. In 1658 the Dutch expelled the Portuguese. In 1795 the British expelled the Dutch. The island at first belonged to the East India company, but in 1802 reverted to the British crown. In 1815 the Candians, whose territory occupied the entire interior of the island, and who were independent of foreign rule, incautiously called upon the British to depose their tyrannous prince. This proved a convenient opportunity for the annexation of this valuable territory. In 1817 an extensive rebellion was successfully put down. In 1843 and 1848 there were minor attempts at rebellion.—The population (exclusive of Europeans) consists of 4 classes: the native Cingalese; Moors, who are found in all parts of the island; Veddahs, a savage, perhaps aboriginal race, inhabiting the mountain fastnesses, and devoid of civilization; and the Malabar and other Hindoos, who immigrate from the neighboring continent. Of all these, the Candian Ceylonese are the finest. The religion of Buddha is the dominant native creed. There are 4 great political castes, and 24 minor ones. The Cingalese are singularly mild and inoffensive in their manners, and make

to yield profitable return. Of coffee, the cultivation only from 1834, the yield in cwt. The average yield per cwt. Cinnamon is exported about 5,100 bales per annum. greatly with the mode of cultivation between 50 and 500 lbs. per 100 lbs. The planting of coconuts for the sake of their oil, has of late been prosecuted by Europeans. Indians were engaged in weaving tablecloths, chiefs, and napkins. The salt from salt marshes yields the revenue of £31,222. Exports of 407,960 galls.; of coir rope, 400,000 lbs. 3/4 are to Great Britain. From Great Britain, the remainder of British goods imported are cotton, glassware, hardware, metals, &c. The foreign trade, which employs only 2,500 vessels, engaged in inward and outward bound vessels, the trade is carried on by about 3,000 (Ceylon), tonnage about 80,000 *dhomies* (a craft peculiar to Ceylon) about 25,000. The bank

India, and the small native dealers, called chittars, to their connections with Madras and Bombay merchants. The value of exports in 1857 was £2,250,000, and of imports nearly £2,000,000. Adding specie, the aggregate value of the whole trade of Ceylon in 1857 was £5,124.

The large imports from Australia consisted almost wholly of specie, the Australian gold coinage having by a recent enactment been made current in Ceylon. The imports from British India consisted of grain to the extent of £500,000, and that of specie largely exceeded that amount. A larger proportion of native coffee having been shipped direct to France in 1857, the balance of trade was against that country. In 1858, however, the experiment of direct coffee exports to France has not been repeated to the same extent. To Holland and Australia the exports were extensive. The following table gives the exports of the coffee crop of 1857-'8:

EXPORTS FROM CEYLON FROM OCT. 1, 1857, TO JUNE 24, 1858.

	Plantation Coffee, cwt.	Native Coffee, cwt.	Total cwt.
London .....	260,284	60,551	320,835
Liverpool .....	8,729	3,231	11,960
France .....	3,671	44,309	47,980

Various countries .....	.....	163	163
Total .....	328,654	184,293	512,947

The total produce of the season 1857-'8 is estimated at 860,000 cwt. plantation coffee; 165,000 cwt. native coffee; total, 1,025,000 cwt.; showing an increase upon the preceding year of 14,000 cwt. in the native coffee, and a decrease of 4,000 cwt. in the plantation coffee.—Books on Ceylon have been published by Knox, in 1857, new edition, 1807; by Perceval, in 1808; by Cordier, in 1807; by Davy, in 1821; by Forbes, in 1840; by Selkirk, in 1844; by Knighton, in 1845; by Pridham, in 1849; by Barr, in 1850; and by Sir John Barrow, in 1857 ("Ceylon, Past and Present"). Among the various newspapers published in Ceylon, the "Ceylon Observer" holds a prominent position.

CHABERT, J. XAVIER, called the fire king, a Frenchman who excited attention in London in 1829, and subsequently in New York, where he still resides, by swallowing 10 to 20 grains of phosphorus, a teaspoonful of prussic acid, and also exposing himself to the heat of an oven, with the thermometer standing at 880°; his pulse was then beating 160 in a minute. According to his statement, the antidote which he used was extremely simple, but he would not tell his secret, notwithstanding the tempting offers made to him by London physicians who witnessed his experiments.

CHABERT, JOSEPH BERNARD, marquis of, a

French navigator and astronomer, born in Toulon, Feb. 28, 1724, died in Paris, Dec. 1, 1805. He was an enthusiastic topographer, and planned and executed maps of the shores of N. America and the Mediterranean, and especially of Greece. He entered the naval service in 1741; in 1758 he became a member of the French academy; in 1781 he was made commander of a squadron; he lost his sight through over study in 1800; and in 1804 was appointed a member of the board of longitude. He was an accurate observer, and a patient, industrious, and persevering hydrographer. He was chiefly employed in America and the Mediterranean. One of his principal works comprises his observations on the American coast, and is entitled *Voyages sur les côtes de l'Amérique Septentrionale*, Paris, 1782. A pension of \$800 was conferred by Napoleon on his widow in 1806.

CHABLAIS, one of the 3 provinces of the administrative division of Annecy in Savoy, kingdom of Sardinia, bounded N. by the lake of Geneva, S. by the province of Faucigny, W. by the canton of Geneva, and E. by the Valais; area 856 sq. in.; pop. 57,562. The country is mountainous, possesses fertile valleys, with rich pastures and fine forests. Corn, wine, and fruit, especially chestnuts and walnuts, abound. The principal articles of trade are grain, cattle, cheese, and timber. Building stone is extensively exported to Geneva. The great Simplon road traverses the northern part of the province. The Romans reared horses in this province, whence its name *Caballica provincia*, *Caballicus ager*, or *Chablasium*. In the middle ages it formed part of Burgundy. In the 10th century it was given by the German emperor Conrad to Humbert, first count of Savoy, whose descendants assumed, in the 14th century, the title of counts of Chablais. Afterward united to France, and forming part of the Leman department under the empire, it was restored to Savoy in 1814, and became one of the neutral provinces of Sardinia. The chief town is Thonon, where the governor resides.

CHABLIS (anc. *Cabliacum*), a canton and small town in the French department of Yonne, in Champagne; pop. of the canton, which is divided into 14 communes, 8,879, and of the town 2,700. There are in the canton 2 manufactories of silk, 2 of earthenware, a tannery, and 3 mills. The principal article of trade is wine. The best qualities are those of Valmur, Clos, Vaudesir, Bouguereau, and Mont du Milieu. (See *BURGUNDY WINES*.)

CHABOT, FRANÇOIS, a French terrorist, born in 1759, died April 5, 1794. He was the son of a cook, became a Capuchin friar, was appointed grand vicar of the bishop of Blois, and in 1791 was sent to the legislative assembly. He became conspicuous by the violence of his democratic zeal, and declared in one of his speeches that "the citizen Jesus Christ was the first sans-culotte." Chabot was the first to apply to well-dressed young men the name of *sans-culottes*; in his person and dress he affected

the most extravagant neglect, and he proposed to expel from France all persons except those whose hands were unwashed. At length, however, he lent himself to the machinations which were set on foot by the enemies of the revolution. An Austrian banker of the name of Frey, one of their most active agents, gained him over by giving him his sister in marriage with a dowry of \$40,000. Chabot, whose head was turned by this sudden fortune, soon became implicated in various suspicious operations, and was finally guillotined.

CHABOT, PHILIPPE DE, a French general, born toward the end of the 15th century, died June 1, 1548. Descended from an ancient family of Poitou, he was brought up with Francis I. Having bravely defended Marseilles in 1524, he was made prisoner at Pavia in 1525. Appointed admiral immediately after his release, he was sent to Italy in 1529 to negotiate the ratification of the treaty of Cambrai by Charles V. Made commander-in-chief of the forces in Savoy in 1535, he effected the conquest of part of that country and of Piedmont, but was censured for not following up his victory. On his return to France charges of frauds upon the national treasury were brought against him by the constable of Montmorenci. Found guilty and imprisoned, he was soon afterward pardoned by the king at the urgent solicitation of the duchess d'Étampes, and reinstated in his position after the disgrace of Montmorenci. He is said to have been the first to suggest the project of colonizing Canada. A collection of his letters written in 1525 is in the imperial library of Paris. A monument, dedicated to him by his son Léonor (the same who during his governorship of Burgundy refused to carry out the orders of Charles IX. to enact in that part of the country the horrors of the St. Bartholomew night), is now in the Louvre.

CHABRIAS, an Athenian general, killed in the harbor of Chios 358 or 357 B. C. In 393 he succeeded Iphicrates in the command of the Athenian forces before Corinth, was afterward sent to chastise the Æginetes for depredations on the coast of Attica, and assisted Evagoras in Cyprus, and Acoris in Egypt, against the Persians. In 378 he commanded the army which the Athenians sent to the aid of Thebes against the Lacedæmonians, under Agesilaus, on which occasion he saved his troops from impending defeat by a military manoeuvre renowned in antiquity, commanding them to await the attack of the enemy with pointed spear and shield, resting on one knee. In 376 he won an important victory over the Lacedæmonian fleet off Naxos. The Athenians having abandoned the alliance of Thebes, he defended Corinth against Epaminondas. A few years later he went on his own account to Egypt, where he commanded the naval forces of Tachos, then in rebellion against the Persians, whose cause, however, after the desertion of the Spartans, he gave up as hopeless. After his return to Athens, he took part in the expedi-

tion against Thrace at the outbreak of the called social war. At the siege of Callinicus his vessel was the first to enter the harbor, but coming isolated and disabled was soon done; he alone refused to save his life, fighting. He was the last of the great generals. Demosthenes said of him: "He who conquered 17 cities, took 70 vessels, many prisoners, and enriched the treasury of Athens with 110 talents. One of his maxims, which he was celebrated, was that an army led by a lion is superior to an army led by a stag. His life was written by C.

CHACHAPOYAS, a district of Peru province of Truxillo, department of Lambayeque on the frontier of Ecuador, intersected by the central branches of the Andes, and by the Chachapoyas, which flows N. W. through the district and falls into the Marañon. The length and breadth of the district are respectively 100 m.; pop. about 12,000. The mountains are extremely cold and the valleys are very hot. Wheat, maize, various fruits and herbs, sugar, cocoa, indigo, cotton, and tobacco in peculiar abundance. Cattle, horses, and sheep are raised. Weaving of cotton is also a favorite industry. Few vestiges remain of the former wealth of the country. There are no mines, and only one gold mine.—CHACHAPOYAS, or SAN JUAN DE LA FRONTERA, the chief place of much trade, especially in cotton, which is raised in great quantities in the neighborhood. It is situated near the W. base of the E. Andes, 185 m. N. E. of Truxillo, 70 m. E. N. E. from Caxamarca. Population estimated at 5,000 and 3,000.

CHACO, EL GRAN, an extensive region in South America, lying in the centre of the continent, between lat. 18° and 28° S. and 63° W., being the most northern of the plains which occupy the surface of the province of Plata, extending on the E. of the Andes to the region as far as the banks of the Parana. It is bounded on the N. by the boundary of the republic of Paraguay, at the confluence of the Salado with the Rio Uruguay, occupying the whole tract between them. This immense tract of country covers an area of about 120,000 square miles. The important tributaries of the Rio Uruguay which traverse the country are the Pilcomayo, Bermejo, and others. The attempts at navigation on the Rio Uruguay have failed, owing to the tortuous course and the shallowness of its waters, rendering steamboat navigation on the Bermejo proved to be practicable, at least in the summer of the year. The climate is extremely hot in the E. mountainous regions, and very cold in the low valleys. There are few trees in the country, and the soil is in general of ordinary fertility. Palm trees, orange, melon, fig, cotton, cocoa, and other trees abound. Of animals, horses, oxen, sheep, vicuña, otters, monkeys, and apes.

ety; and also bees yielding wax in it. The country is destined to become of importance in South America as soon as communications are thoroughly established. Known at present concerning the number of inhabitants. They are mostly roving, including the Tobayas, Guaranés, Payand and other tribes.

CHAD, CHAD, TOHADDA, TSAD, or BÉ- river of Guinea, joining the Quorra 7' N., long. 7° 3' E. It is larger than the river at the junction, and was supposed to form the principal outlet for the waters of Lake Tchad. Vessels can ascend the river from the gulf of Guinea to the town of Jacobah on the latter river. (HOWE.)

CHALONEA, a town of Boeotia on the river the Cephissus, near the frontier of Macedonia, renowned for the great battle in which Philip the Macedon defeated the Athenians, the Thebans, and Thebans (338 B. C.). This battle was won chiefly by the valor of Alexander, then a youth of 18, who commanded the vanguard of his father's army, and broke the band of the Thebans by the attack of the Macedonian phalanx. It made Macedonia the master of Greece. Another battle was fought here (86 B. C.), and won by Sylla, over Mithridates, king of Pontus, under Lucullus. Some remnants of the ancient city are still visible at the village of Capurna, a theatre on the mound of the slaughter-bans, an aqueduct, and a broken marble

of the dry calyx of the grasses and the name is also sometimes applied to cut into short lengths for mixing with lime, &c., to make what is called chopped lime, which is the chaff used by the ancients with clay in the manufacture of brick. CHAFFINCH (*fringilla caelebs*, Linn.), one of the most common and most beautiful of the finch family, and a native of Europe. The male bill varies according to the season, blue to a pale reddish brown; the throat hazel; the forehead black; upper part of head and hind neck grayish blue; back brown; fore neck and breast purplish blue; rump yellowish green; the wing coverts black, the secondary tipped with white, the smaller black and grayish with white; the quill feathers white at the base along the inner margin; the tail feathers black, the exterior feather obliquely tipped with white, including the middle of the tail and the terminal third of the inner; the inner slightly margined with white inter-tipped with the same on the inner; the middle feathers brownish gray, black at the shafts. Female with the upper part of head and the back light grayish brown; the throat yellowish green; the breast pale yellow. Young like the female, with the

Length of the male 6½ inches; expanse of wings 11½ inches; bill ½ an inch;

tarsus ½ of an inch; the female is a trifle smaller. The variations from these colors are slight, though the tips of the feathers get considerably worn, giving a brighter appearance to the plumage of the head, back, and breast. The chaffinch is a permanent resident in Great Britain, though in corresponding latitudes on the continent it migrates southward. Its notes are monotonous, generally *twink, twink*, repeated 8 or 4 times; hence its provincial name of twink; it is almost constantly heard in the lanes and gardens from May 1 to the middle of June. In summer they live chiefly on insects, with which they feed their young; in winter they become gregarious and frequent the fields, farm-yards, and roads, in search of seeds and grain, to aid the digestion of which they swallow smooth particles of gravel. Their flight is rapid, with frequent undulations; on the ground they move with short leaps. The nest is very neatly constructed of moss, lichens, wool, feathers, and hair, and is generally of such a gray color as to be seen with difficulty in the cleft of the lichen-covered trees. The eggs are 4 or 5 in number, about ½ of an inch long, of a purplish white or pale reddish gray color, with a few spots and lines of reddish brown. The chaffinch is one of the most familiar birds, and, with the sparrows and buntings, in the winter will come in flocks around the doors of the farm-houses. They prepare to breed in April, and hatch their first brood by the middle of May, and a second by the end of July. The chaffinch is much esteemed in Germany as a song bird, and from its beauty it is occasionally seen as a parlor ornament elsewhere.

CHAGRES, a seaport town of New Granada, at the mouth of Chagres river, on the N. coast of the isthmus of Panama. It is built on both sides of the river, the left part being called the American town, inhabited chiefly by natives of the United States, and the right part the old Spanish or Indian town, with negroes, half-breeds, Mexicans, Spanish, and a few English. The former is composed of wood houses, the latter mainly of huts thatched with palmetto, and contains an old church. The harbor is difficult of entrance and very shallow. The Panama railroad, across the isthmus, commences at Aspinwall, about 8 m. N. E. of Chagres.

CHAGRES RIVER, of New Granada, rises about 80 m. N. E. of Panama, flows at first W., then N., and after traversing a fertile country enters the Caribbean sea, on the N. coast of the isthmus of Panama. Navigation is rendered difficult by the great rapidity of the river and its numerous rapids.

CHAILLOT, one of the suburbs of Paris, situated beyond the Champs Élysées, between the avenue of Neuilly and the river Seine. It was of old renowned as the seat of a convent; it is now important as a manufacturing place.

CHAIN, a measure of length, formed of links of iron wire; a surveyor's chain having 100 links, each 7.92 inches in length. Engineers,

branching on the sides, one branch going to the ring in front, the other to the ring behind, causing a nearly continuous waving white line on the sides from the neck to the vent; alternating with the dorsal bars there are irregular white blotches reaching to the abdomen, which is shining violet black; the tail has 4 or 5 transverse rings. In a specimen 42 inches long, the head measured a little over an inch, the body 36 inches, and the tail 5 inches; they attain a length of more than 4 feet. Though fond of moist and shady places, it does not take to the water or to trees; it feeds on moles, mice, small birds, and reptiles, and even other snakes. It is found from New York to Florida; its western limit is not positively known. The abdominal plates are about 215 in number, and the bifid sub-caudal scales from 40 to 50.

CHAINS, a place, or ledge, built on the outside of a ship, abreast of her lower rigging, and projecting from her side. The shrouds are brought down to the outsides, and the chains thus act as permanent outriggers, giving the lower rigging a wider spread than it could otherwise have, and affording the mast a firmer support. Chains are now little used except in large men-of-war.—CHAIN PLATES are plates

fallen under the dominion of the East. Its walls were destroyed by the Saracens, now but a poor village. In ecclesiastical history it is celebrated as the seat of the second ecumenical council, convoked A. D. 451, by the emperor Marcian, to condemn Eutyches concerning the two natures, and to counteract the bad effect of a synod authorized assembly held at Ephesus, which the title of *Latrocinium*, or Robbery, has commonly been applied. It was designated as the place of meeting to settle the disturbances created there by the heresies of Dioscorus, who had presided at the first synod, induced the emperor to remove nearer his capital. According to tradition, chiefly from the East, assembled at St. Euphemia, at Chalcedon, under Leo I., afterward called the Great, and his legates. The creeds of Nice and Constantinople were adopted as the rule, and after a prolonged discussion the *Lati-  
sinum*, as well as the doctrines of Eutyches and Dioscorus, in favor of which he had pronounced, was condemned. The delegates professed their belief in the existence of two natures in Christ, and declared that

promulgated, among which was the celebrated decree, opposed by the Roman legates, made the see of Constantinople equal in rank and jurisdiction, and next in rank, to that of Rome. It was also ordered that no bishop should take money for ordination, that no ecclesiastic should undertake the administration of the temporal matters of the church, that widows and orphans, forsake the church, and any other office, go before a lay tribunal, that more than one benefice. Bishops were forbidden to divide their provinces, and were to have control over the clergy in monasteries. Priests were forbidden to be appointed under the age of 40. Differences were adjusted between the sees of Antioch and Jerusalem, Alexandria and Nice; and Theodoret, deposed by the emperor Flavian, was restored to his see. These decrees were confirmed by the council of Chalcedon, with the exception of the one relating to the see of Constantinople, and throughout the church the council has always been held in high veneration.

**CHALCEDONY**, one of the numerous varieties of the quartz family, which are distinguished from each other, not by difference of chemical composition, but by their peculiar crystalline form, markings, and colors. The varieties of chalcedony consist principally of the mammillary, botryoidal, and stalactitic forms, and its waxy or horny lustre and texture. It is found lining cavities in trap, and in other rocks, being arranged in concentric layers, precisely as if its particles had been introduced in a gaseous or fluid form. The intermixture of opal with the purely siliceous layers proves that water was present during the production of the mineral incrustation.

By the variety of its colors and the high polish it acquires by polishing, chalcedony is highly esteemed as an ornamental stone, though its great hardness renders it very difficult to work. In several of the countries of Asia it is common to find articles of this stone, as cups, vases, &c., of the most exquisite workmanship, as delicate as the finest chinaware, and such as could never be attempted by any of the more civilized nations. Specimens of the finest texture and most delicate shades are selected for jewelry, especially such as are more or less transparent, passing into transparent and brown. In Europe the stone is worked with the same skill as at Oberstein, and for the same purposes which have already been mentioned under **AGATE**. Some of the finest known specimens of chalcedony were found at the Tresavean mine in Cornwall. They occurred in a large vug or cavity in the mine, and none were found like them. One of them, described as resembling the anatomized wing of a great bat, displaying its bones and arteries, is preserved in the British museum. The mineral is frequently met with in the United States, and particularly abundant where metallic veins are worked, but no specimens of extraordinary size are found.

**CHALCHIHUITL**, the Indian name of a green-colored stone, held in high repute by the ancient Mexicans, and by the Indian tribes now inhabiting the northern and western portions of New Mexico. They possess the art of fashioning it into ornaments, as beads and other trinkets, and occasionally use it in trade, valuing it more highly than gold. It proves, according to the researches of Mr. W. P. Blake, who has published an article upon it in the "American Journal of Science" (March, 1858), to be turquoise. The locality, at which it has been obtained from remote periods, is in the mountains called Los Oerrillos, 20 m. S. E. from Santa Fé. A quarry of extraordinary extent has been excavated in a granular light-colored porphyry; and around it are a number of smaller excavations. Mr. Blake describes the great pit as appearing, from the top of the cliff, "200 feet in depth, and 800 or more in width." Pine trees more than 100 years old are growing upon the debris in the bottom and about the sides. These excavations were evidently made before the conquest of the country by the Spaniards, though the Indians still continue to visit the locality to search among the debris for more crystals. The earliest historians, as Bernal Diaz, who accompanied Cortes, and others, make mention of chalchihuitls among the presents made by Montezuma, intended especially for the Spanish sovereign. Mr. Blake proposes that the name be retained by mineralogists for this New Mexican variety of turquoise. The Indian pronunciation of it is chal-che-we-ta.

**CHALCIDIUS**, a Platonic philosopher, who flourished probably in the 6th century A. D. He is described upon the manuscripts of his work as *vir clarissimus*, and these vague words are the only allusions which we have to his life. There remains from him a Latin translation of the first part of the "Timæus" of Plato, with a learned commentary. This work is dedicated to a certain Osius, who has been by some regarded, without however any evidence of it, as the archbishop Osius, who took a leading part in the debates of the council of Nice in 325. Giraldi and Bruckér have maintained that Chalcidius was a Christian, Goujet and Moehle, that he was a pagan. The last and best edition of his commentary is that of Fabricius, at the end of the second volume of the works of St. Hippolytus (Hamburg, 1718).

**CHALOIS**, or **Næxoront**, the largest and most important city of Eubœa, the ancient name for the island of Egripos, lying immediately off the E. shore of Bœotia, now Livadia, from which it is separated only by the narrow straits of the Euripus, which is evidently the origin of the modern name Egripos. The city and fortress, which was one of the strongest and most important of ancient Greece, is situated at the very narrowest part of the strait, which is formed by the crowding forward of a projecting spur of the mountain of Karababa, on the mainland, and the corresponding protrusion of a rocky promontory on the island side. Immediately on

castle. A stone bridge, 60 or 70 feet in length, connects the Boeotian shore with this castle. A wooden bridge, about 35 feet long, which may be raised at both ends, for the purpose of admitting the passage of vessels, communicates from the small castle to the gate of Castro, which is in a tower projecting from the walls. It appears that the round tower is a Venetian work, the rest of the fortifications Turkish. Col. Leake could find no vestiges of ancient Chalcis, except a few fragments of white marble in the walls of mosques and houses, and the bust of a statue in the wall of a house in the fortress. The lion of St. Mark remains over the gates of Castro, many of the better houses of which are of Venetian construction, and there is a church with a high pointed roof, a square tower, and Gothic windows, which was probably built by the same people, as they were in almost constant possession of the place for 3 centuries preceding its capture by Mohammed II. in 1470.

CHALDEA was properly the name of the S. W. part of ancient Babylonia, bordering on the N. E. confines of Arabia. So it is mentioned by Ptolemy the geographer. Strabo also speaks of a Chaldean tribe living in that region.

name supporting his opinion. of this people, particularly its evolved in great obscurity, and it be seen whether the discoveries made in the ruins of Babylon, Susa, which throw a new light on the subject, and the results of which are systematically arranged in George Rawlinson's work on Herodotus (London, 1851). Rawlinson's work is a valuable contribution to the study of the difficulties. Rawlinson, a hunter, who is mentioned in the Bible as the founder of the empire of the Medes, which is afterward styled the land of the Medes, is a Hamite, and seems to have been the conqueror of the Medes, at least in the almost generally adopted explanation of the name, which speaks of him. The name Belus as the founder of the same empire is said in the Bible about the time of the king of Babylon, who belonged to Amraphel, the king of Babylon, who fought a battle with the days of Abraham; and a few centuries separates the first mention of the name in connection with the Ur of the patriarch, from its mention in scriptural history, in the Bible, except their being mentioned in the Bible.

conclusion that Babylonia, having been by Nimrod or Belus, be these names or not, had reached a high degree of light, and glory, before it was conquered by a warlike tribe who made Babylon the seat of greater conquests, power, and glory. "the beauty of the Chaldees' excellency" is called in Scripture, the *Chaldæum caput*, as Pliny calls it. Thus the origin of this nation, as masters of Babylonia, should be dated either from the year 3760, the first of the so-called Chaldean era, or from the reign of Nabopolassar in the astronomical canon of Berosus, which makes him the first of a series of kings of this nation who ruled the empire from the fall of the first Assyrian empire to the reign of Nabopolassar, who, with Cyaxares, king of the Medes, broke, and conquered even the capital of the Assyrian state, thus founding the independence of Babylonia, and its predominance in Asia, which his son Nebuchadnezzar extended. But this conclusion is shaken by the circumstance that Babylon has never been already the seat, in the early periods of history, of a system of religion and science, which in antiquity is generally attributed to the genius and glory of the Chaldeans, whose name in Greek and classical antiquity designates a nation, but also the peculiar priestly class devoted to the sacred science of astrology; as is mentioned that Callisthenes, who accompanied Alexander on his expedition to Persia, found a collection of astronomical observations made by the Chaldeans in the temple of Bel, which he used as an observatory, during a period of nearly 2,000 years. It is moreover shaken by the fragments of the Babylonian Berosus, preserved in Josephus, and others, which, though full of exaggerations, at least prove a very ancient origin of the Chaldeans were the earliest or earliest organizers of Babylonian civilization. Berosus speaks of an antediluvian dynasty of Chaldean kings, the first of whom was Xisuthros, in whose time, after the great flood, the description of his reign has a great resemblance to that of the Noah. During the reign of the 3d of this dynasty, Oannes (supposed by some to be the serpent), an extraordinary being, half fish, speaking with a human voice, came up from the waves of the Erythraean sea to the inhabitants of the shore religion and science, art, and industry, retiring every day to the sea and reappearing every morning. His successors became the civilizers of Babylonia. They are called Chaldeans, being perhaps allegorical representations of chief priests, or of propitious genii who have inspired as many sacred sciences, worship and science. These were Xisuthros at the time of the flood, and his son, Sippara, where they were found. Some critics have seen in

this myth of Oannes a confirmation of a relation of Diodorus, according to which a colony from Egypt headed by Belus, the son of Poseidon and Libya, carried the science of their land over the sea, to the inhabitants of the Babylonian plains, which served to vindicate the claims of the Egyptians for the priority of their astronomical knowledge over that of their great Asiatic rivals; while others regarded the Chaldeans as the fathers of astronomy, and their country as the focus of this science, whence it spread to India, Egypt, and the West. The 2d and 3d dynasties of the 86 postdiluvian kings of Berosus are also Chaldean. The most plausible way of reconciling the discrepancies in the testimony of the ancients, seemed to be to the critics of the school of Gesenius, whose dissertation on the Chaldeans in the *Encyclopædie* of Ersch and Gruber was long regarded as the best solution, to sum up the history of the Chaldeans as follows. Their first home is either in the mountains of Armenia, or somewhat further N. in those of the Caucasus, or further S. in those of Koordistan, their scriptural ancestor being either Arphaxad, son of Shem, or Choesed, son of Nahor, likewise a Shemite. They spread over Mesopotamia and make incursions into Babylonia. A colony of them, soon after the foundation of Babylon, establishes the influence of their priest caste in that state. Like the Brahmins of India, they rule the public worship, and through it the laws and manners of the Babylonians. They develop art, industry, and commerce, but above all the science of astronomy and astrology. They occupy the highest rank in the state, and its governors or viceroys, in the period of subjection to Assyria, are chosen from their body, of which is also Nabonassar, who heads the series of 19 Chaldean princes mentioned in the *Almagest* of Ptolemy (from 747 B. C.), probably vassals of the Assyrian empire. One of these princes is Merodach Baladan (mentioned also under this name by Berosus, and under that of Mardakempad by Ptolemy), who, in the time of Sennacherib, sends ambassadors to Hezekiah, king of Judah, probably with the object of forming an alliance against the common oppressor. His successor, Belibus, is carried away as captive by Sennacherib, who makes his own son, Esarhaddon (the Asordan of Berosus), viceroy of Babylonia. In the mean time, the stock of the Chaldean nation remains in their native mountains, warlike, fierce, and predatory. They appear as plundering invaders in the book of Job, and at a late period as Persian soldiers in the history of Herodotus, and as a warlike mountain tribe in the *Anabasis* of Xenophon. Strengthened by new immigrations of this warlike people, Nabopolassar, the Chaldean viceroy of Babylonia, shakes off the yoke of New Assyria, destroys Nineveh with Cyaxares, and thus becomes the founder of the Chaldean empire, now properly so called, whose limits, might, and glory are vastly extended by his

THE OTHER AND DAILY NATION OF THE CHALDEANS disappears as such, and its name is preserved for some time only in scattered tribes, and its glory in the science of its priests. The determination of the lunar periods, that of the equinoctial and solstitial points, a more precise definition of the solar year, the division of the ecliptic into 12 equal parts, that of the day into hours, the signs, names, and figures of the zodiac, the invention of the dial, are among the improvements in astronomy attributed to the knowledge of the Chaldeans. In their religion, so closely connected with their science, light is the chief element, and the Sun, the Moon, Saturn, Jupiter, Mars, Venus, Mercury, and other stars, as well as the constellations of the zodiac, are chief objects of adoration, worshipped in temples with sacrifices and festivals; though it may be hard to define precisely to which heavenly bodies are to be applied the names of Bel, Gad, Nebo, Merodach, Nergal, their divinities mentioned in Scripture, or those of Salambo, Turrah, Derketo and Mylitta, which are spoken of in profane writers. Their legends speak also of the monsters of the chaos, of Amorca, or primitive night. With the decline of Babylon their science sinks, and Chaldeans are

MENTS OF THE STATE WOULD BE HARMED and registered, astronomical formed, and a chronological thereupon, such as we find to uninterrupted to the days and Berossus. A system of which aimed at the command through the rude representation jects, belonged, as it would be the tribes who descended the Nile, but to those also who, pe from the same focus, passed east ley of the Euphrates. In the ment, too, of the systems which society called forth, a very similar be presumed to have been follow visions of the Hamite race, the being reduced in process of time for the convenience of sculpture characters being assigned phones corresponded with the names represented." "To the primitive nasy, which is represented, in Bible by Nimrod, the son of Cush of Ham, the 2 earliest of the men Uruk and Ilgi, may be assigned to Berossus, the chronological

mar and Ellasar, who fought under his banner in the Syrian war, as subordinate chiefs, and Tidal, who led a contingent of Median Scyths belonging to the old population, may have been the local governors who had submitted to his power when he invaded Chaldea." Cheder-laomer is probably the Kudur-mapula of the inscriptions, and the Elamite founder of the 2d Hamite dynasty of Babylon, termed Chaldean by Berosus, whose historical dates are in the main confirmed by the inscriptions. Ismi-dagon, who reigned about 1861 B. C., extended the Chaldean power over Assyria. Merodach-namana (about 1675 B. C.) is the first who is styled king of Babylon. "On the subject of the Arabian dynasty (1518-1273 B. C.), which, according to Berosus, succeeded the Chaldean on the Euphrates, nothing certain is ascertained from the monuments. The Arabians formed an important element of the population of the Mesopotamian valley from the earliest times." The predominance of Assyria lasted probably from 1273 to 747 B. C. During these 526 years the history of the subordinate Babylonia is, with few exceptions, a blank. The era of Nabonassar (747 B. C.), which has no historical importance, marks the date of a great revolution. Of the successors of Nabonassar, Merodach Baladan was conquered by Sargon, king of Assyria, regained his kingdom, and was again deprived of it by Sennacherib, the son of Sargon, who plundered Babylon, ravaged the whole country, destroyed 79 cities and 820 villages, burned the palaces of the kings, and carried off the skilled workmen and the women. Babylonia was then governed by Asshur-nadin and Belibus, viceroys of the Assyrian monarch, or independent kings, until Esar-haddon, the son of Sennacherib, united the 2 thrones. Babylonia remained in subjection to the time of Nabopolassar (625 B. C.), who rebelled against Saracus, the last king of Assyria, and with whom the later and greater Babylonian empire commences, which flourishes particularly under Nebuchadnezzar, the son of Nabopolassar, and ends with Nabonidus and his son Belshazzar (538 B. C.). The most remarkable divinities of the inscriptions, whose stellar and mythological character, however, can hardly be traced amid the endless confusion of names, titles, epithets, and signs, are Ra or Il, Anu, Bil, Hêa or Hoa, Biltâ or Beltis, Iva, San, Sin, Ninip, Bel-Merodach, Nergal, Ishtar, Nebo, Allata, Bel-Zirpu, &c. An attentive comparison of the different theories will at once show that many questions are still to be solved, and many objections to be answered; but still a solution may be hoped for that will reconcile all difficulties.

CHALDEE LANGUAGE is the eastern dialect of the Aramaic, of which the Syriac is the western, and which forms the northern branch of the Semitic tongues, the Hebrew, the Arabic, and some other minor dialects forming the southern branch. As the language of Babylonia in the time of its national greatness, whence it was brought by the Jews after their captivity

to Palestine, it is also called Babylonic. The Chaldee is known to us only through the writings of Jews, every trace of national literature in this language, if there was any such, having disappeared. The history of the Babylonian priest Berosus, of which fragments have been saved, was originally written in Greek. Beside a few words in Genesis (xxxi. 47), and Jeremiah (x. 11), we have in the Hebrew canon several chapters of Daniel (from ii. 4 to vii. 28), and Ezra (from iv. 8 to vi. 18, and vii. from 12 to 26), written in this language; and of works of later Jewish writers, the different Chaldaic translations and paraphrases (*Targumim*) of various parts of the Bible, the 2 Talmuds, and some more modern productions. The apocryphal books of Tobit, Judith, and Maccabees, as well as the history of the Jewish war by Josephus, are also supposed to have been originally written in Chaldaic, this idiom having become by degrees the common language of the Jews after the Babylonish captivity, and particularly from the times of the Maccabees. Of the Targums, that of Onkelos (probably written in Babylonia in the 1st century), a strict translation of the Pentateuch, is distinguished by the purity of its idiom, surpassing that of the biblical fragments; that of Jonathan ben Uziel, a paraphrase of the historic and prophetic books, composed in the 1st or 2d century, and the Pseudo-Jonathan and Hierosolymitan paraphrases of the Pentateuch, of much later date, are less pure and valuable. Of the Talmuds only the Gemaras or the commentaries are composed in a Chaldaic idiom, which is greatly corrupt, chiefly in that of Jerusalem, and requires a particular study; while the shorter and elder Mishna, or the text, is Hebrew, though with Aramaic features. After the conquest of Babylonia by the Arabs in the year 640, the use of the Chaldee language gradually ceased; and it is now spoken only in a few mostly Christian communities in the mountains of Koordistan. As a dialect it is distinguished from the Syriac by its avoiding diphthongs and the vowel *o*, for which it generally has *â*, by the use of *Dagesh forte*, as well as by generally accenting the last syllable, and a less defective writing; from the Hebrew, with which it has a common alphabet, by broadness, by substituting labial for hissing sounds, *q* for *q* and *q*, *o* for *o*, and by comparative poverty in vowels. In forms it is poorer than both the Hebrew and Syriac. To the best grammars of this language belong those of Buxtorf, Michaelis, Harris ("Elements of the Chaldaic Language," London, 1822), Fürst (Leipsic, 1835), Petermann (1841), Winer (Leipsic, 1842), and Bertheau (Göttingen, 1843). The great dictionary of Nathan bar Jachiel of Rome (of the 11th century), entitled *Aruch*, and enriched with additions by Mussaphiah, has been published in a more modern form by Landau (5 vols. Prague, 1819 and after). Buxtorf's *Lexicon Chaldaicum Talmudicum et Rabbinicum* (Basel, 1640), is founded upon it. Luzzato's *Oheb-Gez*, and Geiger's *Lehr- und*

*Lesbuch zur Sprache der Mischna* (Breslau, 1845), are valuable contributions.

CHALDRON, an English measure containing 86 bushels, used chiefly in the measurement of coal.

CHÂLET (Ger. *Sennhütte*), the name for the log huts in Switzerland in which the herdsmen reside. They are made of pine logs, notched at the extremities so as to fit together at the angles of the building where they cross. The roof is low and flat, covered with stones to protect it against the elements. The interior has scarcely any thing beyond the apparatus of the dairy, including a large kettle for heating the milk. In the loft above is a store of straw to serve as beds. The entrance is difficult, the ground outside being broken by the feet of cattle, and covered with heaps of mud and dung. In the Semmenthal alone there are about 10,000 châteaux, and all pastoral Swiss valleys are covered with huts of the kind. The herdsman who resides in the châteaux has to collect about 100 cows twice a day, to look after stragglers, and to make the cheese, which is the principal occupation inside the châteaux. The owners of cattle themselves reside also in châteaux, but they are of a superior kind, and less numerous. Some of these châteaux of the better sort, with their delicious milk, fresh butter, bread, and cheese, offer delightful retreats to the weary traveller.—Another kind of châteaux is a shed or barn, in which the hay is kept until the winter, when it is carried over the snow in sledges down to the villages below.

CHALEUR BAY, an inlet of the gulf of St. Lawrence, separates Lower Canada from New Brunswick. It receives the Restigouche river at its W. extremity, affords excellent anchorage, and is much frequented by mackerel fishers. Its navigation is everywhere safe. Length from E. to W. 90 m.; breadth from 12 to 20 m. A French fleet was defeated here by the British, July, 1760.

CHALFONT ST. GILES, a parish of England, co. of Bucks, on the Great Western railway; pop. 1,228. It was the residence of Milton during the plague in 1665, and the place where he finished "Paradise Lost." In a cemetery of the society of Friends in this parish lie the remains of William Penn, the founder of Pennsylvania.

CHALGROVE FIELD, in Oxfordshire, England, on the railway from London to Gloucester, memorable as the scene of the defeat of the parliamentary forces by the royal troops under Prince Rupert. The celebrated John Hampden was mortally wounded in this battle, June 18, 1643. A monument commemorating this event was erected in 1843, and inaugurated on the 200th anniversary of the day.

CHALICE (Lat. *calix*, a cup), the vessel containing the consecrated wine in the sacrament of the eucharist. In honor of its sacred purpose, it has usually been made of as costly a substance as the circumstances of a church permitted—of glass, crystal, silver, or gold—and

often embellished with sculptures and precious stones. St. Ambrose relates that in period of distress the early Christians sold their chalice to aid the poor.

CHALK, an earthy mineral, consisting of carbonate of lime of friable texture, easily reduced to a white powder. It constitutes vast formations of vast extent, being seen along the coasts of the North sea and the English coast of England and France, towering up in cliffs sometimes 1,000 feet high, that dazzle the eye in sunlight with their brilliant whiteness. The chalk cliffs of England that gave the original name of Albion, in allusion to its white shores. The rock formation of which chalk is the principal member, and which is called the cretaceous, or chalk formation, is the group of the secondary series. It is seen across the continent of Europe from the coast of Ireland toward the S. E. to the Crimea, extending a distance of 1,140 m., and from the S. of Swabia beyond Bordeaux, about 840 m., occupying patches over the greater part of the area. It gives to the topography an interesting variety of abrupt cliffs upon the coasts, and of bold hills in the interior, in every direction with valleys of flowing outline; but the soil it produces is generally too calcareous to be very fertile. A remarkable feature in the chalk at some localities is the occurrence of flint nodules in the rock, horizontally arranged, and not in contact with each other, in various shapes and sizes, varying from an inch to a yard in circumference. The flints frequently appear to be concretions of silica around organic substances, as sponges, &c., into the most minute pores of which the silica has penetrated, thereby preserving their peculiar forms. The chalk itself is in great part composed of fine minute shells and corals, and it is now generally understood to have been derived from the same sources as the fine white calcareous sand which fills the bottoms of coral lagoons, and the fragments of its structures. This is entirely of animal origin, in part composed of shells and corals, and partly of shell-fish, and of certain genera of which, in the coral regions of the South seas Mr. Dana found portions as compact and solid as any secondary rocks, and parts of the still growing corals be distinguished from portions of the rocks of the cretaceous formation. The fossils of this geological group are chiefly foraminifera, but of extinct species. The chalk is found in it in New Jersey, and in the same formation in the United States is absent, though the other rocks and green sand are recognized elsewhere accompany it.—(

a variety of purposes. It is easily converted into lime, in which state it forms a valuable silicifier as well as cement. It is used as a grinding material, and also for polishing metals and glass. When finely ground, and purified by washing and separating its harder particles, is sold by the name of whiting, or Spanish white. The flints found in the formation were once much used in England in the manufacture of glass. In medicine, chalk, when thoroughly purified, is used under the name of prepared chalk, as an absorbent in diarrhoea; it is also an antacid, and is used to furnish carbonic acid; it is also a dentifrice.—French chalk is a pure variety of steatite or talc, used by tailors for marking cloth, and also mixed with cosmetics to give them body.—Black chalk is a variety of bituminous shale, made use of by artists for drawing.—Red chalk, or red-lead, is an argillaceous red oxide of iron.

**CHALKLEY, THOMAS**, a preacher in the society of Friends, arrived in Philadelphia from England at the beginning of the 18th century, labored among the Indians at Conestoga, near the Susquehanna, and died in Tortola in 1741, while engaged in spreading his doctrines in that island. He commenced the foundation of the library of the society of Friends in Philadelphia. His journal and a collection of his writings were published in that city in 1749, and in New York in 1808.

**CHALLENGE.** This word, which is now, except in a legal sense, used solely to imply a provocatory summons to mortal combat, seems originally to have conveyed within itself the idea of an appeal, of an exception taken, or a claim asserted, and a disinclination to submit to some decision or arbitrament, rendered or about to be rendered, and removal of the subject matter of dispute to some other court or tribunal. Thus, in ancient times, the duello was never the mode of settlement of an angry personal dispute; but it was the trial of a solemn cause, before the actual court and in the presence of God. The challenger took exception to the truth of the allegation made against him by his adversary or opponent, and removed the adjudication of the cause, by appeal of challenge, from the human court of law, before which it was pending, to the divine court of equity, which was believed directly to interfere in the event of wagers by battle, and to give the strong arm and the sharp sword to the righteous party. (See **APPEAL**.) In the same sense, when a jury is challenged, whether by the array or by the poll, exception is taken to the fairness of the impanelling of the whole jury, or to the partiality of the individual juror; and, having taken exception, the person accused by his challenge removes the adjudication of his cause from that entire jury, or from that individual as part of it, to some other, by whom he believes he can have a fair trial, which he denies that he can as it is at present constituted.—A challenge as a preliminary to a duel is forbidden by the laws of most of the United States, and in the

American army by the articles of war. Any officer or soldier sending a challenge to another officer or soldier, or accepting a challenge if sent, incurs the penalty, if a commissioned officer, of being cashiered; if a non-commissioned officer or soldier, of suffering corporal punishment. Any officer, who knowingly or willingly suffers any person whatsoever to go forth to fight a duel, is punishable as a challenger, and seconds are not distinguished from principals. The punishment is at the discretion of the court-martial, of which if any member is challenged by a prisoner, that member withdraws, and the court is closed to determine upon the relevancy or validity of the challenge. If the challenge is disallowed, the member resumes his seat.—Challenge is also a hunting term, used of hounds or beagles, when, at first finding the scent of their game, they presently open and cry; the huntsmen then say they challenge.

**CHALMERS, ALEXANDER**, a Scottish biographer and journalist, born in Aberdeen, March 29, 1759, died in London, Dec. 10, 1834. The work on which his celebrity chiefly rests is the "General Biographical Dictionary," 82 vols., commenced in 1812, and completed in 1817. He also published annotated editions of the British essayists, of Shakespeare, and of the English poets from Chaucer to Cowper. In 1820 he published an abridgment of Johnson's English dictionary. During his long literary career he edited works enough to form a moderate-sized library. Among them were the complete writings of Fielding, Johnson, Bolingbroke, and Gibbon, beside individual biographies too numerous to recount. At different periods he was editor of the London "Morning Herald," associate editor of the "Morning Chronicle," and frequent contributor, under the signature of "Senex," to the "St. James's Chronicle," as well as to the critical and analytical reviews. He was a man of exemplary private character. The family of Chalmers still carry on an extensive printing business at Aberdeen.

**CHALMERS, GEORGE**, an English historian, born in 1742, died in 1825. He studied law at Aberdeen, and accompanied an uncle to the North American colonies, where he settled at Baltimore. At the commencement of the revolution, he returned to England. He wrote "An Estimate of the Comparative Strength of Great Britain," and "Political Annals of the United Colonies;" also a historical and topographical account of North Britain from the most ancient times, entitled "Caledonia," the lives of De Foe, Ruddiman, Allan Ramsay, Thomas Paine, and several others.

**CHALMERS, LIONEL**, a physician of South Carolina, and writer of several medical works, born at Campbelltown, Scotland, in 1715, died at Charleston in 1777. He emigrated from Scotland to Christ Church parish, S. C., but soon removed to Charleston, where he practised for 40 years.

**CHALMERS, THOMAS, D.D.**, a Scottish divine, born at Anstruther, in Fifeshire, March 17,

coming a candidate for the chair of natural philosophy at St. Andrew's in 1804, and for the mathematical chair in Edinburgh in 1805. His first effort in authorship was a pamphlet to prove that the vigorous prosecution of science was not incompatible with ministerial duties and habits. On Napoleon's menace of invading England, Chalmers joined a corps of volunteers not only as chaplain but lieutenant. In 1808, upon the alarm created by Napoleon's decrees against British commerce, he published his "Inquiry into the Extent and Stability of National Resources," to show that the apprehensions were groundless, and thus added political economy to the sciences in which he was proficient. He had already become a contributor to the "Edinburgh Encyclopædia," and the article on Christianity was assigned to him. It was in his studies while preparing this article, amid a series of domestic bereavements and a long and severe illness in 1809, which brought him near to the grave, that he experienced a great spiritual change. Then, for the first time, he thought, he saw the gospel of Christ in its true light, and he emerged from his trials with deepened views of the duties of the clerical

likened the impression produced to "what one reads of as the eloquence of Demosthenes," and was equally enthusiastic in his address. "Astronomical Discourses," a series of day lectures on the connection between the coveries of astronomy and the human mind, were published in 1811. His fame had meantime extended to London, where he preached in 1812. In a time of high political excitement, all parties thronged to hear him. As critical as Hazlitt, Wilberforce, Coleridge, Hall, and Foster, could only appreciate him, he was moved to tears, and Wilberforce wrote in his diary: "All the world is wild with him." The article on "Pauquetry" contributed to the "Edinburgh Review" in 1812, after his return to Scotland, was followed by the "Christian and Civic Economy of Great Towns," which soon followed, and was then the direction of his efforts. His aim by a thorough organization of the old parochial system of Scotland

lituro was reduced in 4 years from £280 per annum. Every street and isited periodically by his agents and r economical, educational, and religes. In the great labor of effecting hial arrangement, Edward Irving, beginning of his career, was his as- r. Chalmers had never ceased to as- professorship in one of the Scotch a, and having successfully illustrated story views in his parish, in 1823 he call to the chair of moral philosophy iversity of St. Andrew's. In this office ed 5 years, and its literary results Lectures on Moral Philosophy," and n "Political Economy in connection oral Aspects of Society," which were ay published. He had given a new impulse to the studies in his depart- n in 1828 he was transferred from r's to the wider sphere of the chair of a the university of Edinburgh, where d during the next 15 years. He car- loquence and enthusiasm into the , which was filled not with students with clergymen of every church and of literary and scientific distinction, hear systematic theology propound- cilful a teacher. In 1838 he publish- gewater treatise on the "Adaptation d Nature to the Moral and Intellec- tution of Man;" in 1838 he delivered f lectures in London in defence of ablishments; and after a short visit began an arduous tour through Scot- ture and collect funds in behalf of ent which he had initiated of so in- e number of churches in the country, eighborhood, nor even individual, without the discipline of religion.

h as had never before fallen to a elesiastic, were now crowning his e was elected fellow of the royal Edinburgh, corresponding member of institute of France, and in 1835 re- degree of D.O.L. from the univer- ford. He had become the acknowl- ler of the evangelical party in the Scotland, and in 1832, when that ed the majority, he had received the or which that church can bestow, appointed moderator of the general

In 1834 this assembly, under the the ruling party, after declaring it nciple of the church that no minister struded into any parish contrary to the congregation, passed the famous "by which the displeasure of a ma- e male heads of families, being com- should be a bar to the settlement of . This act was chiefly the work of ers, and the resistance to it made him champions of a violent controversy tish church, and finally the leader of cession from it. Several nominees an rejected by parishioners, appeals

were made successively to the civil courts of Scotland and to the house of lords, and the re- sult was that the veto act was declared to be contrary to the laws of the land. It was affirm- ed by Lords Brougham and Cottenham in their judgments that the church to which a minister was nominated had no legal right to look be- yond his qualifications as to "life, literature, and morals." Thus the law of the church and that of the civil courts were at war, and confu- sion ensued. The crown rebuked and threat- ened the presbyteries if they refused to ordain vetoed nominees, and the churches were active in their own defence. The presbytery of Strath- bogie having decided by a vote of 7 to 8 to or- dain a nominee where an overwhelming major- ity of the congregation dissented, the churches stopped the ordination by suspending the 7 ministers who formed the majority. Then the civil court declared the suspension null, and for- bade all other ministers to preach in their par- ishes. In opposition to ecclesiastical authority the 7 suspended clergymen proceeded with the ordination, and in opposition to civil injunction Dr. Chalmers and other distinguished ministers preached in the interdicted parishes. Collisions became frequent, and the legislature devising no way to heal the breach, a disruption became inevitable; and at the meeting of the general assembly, May 18, 1843, 470 clergymen, follow- ed by a large portion of the people of Scotland, withdrew from the established church, and constituted themselves into the "Free Church of Scotland," electing Dr. Chalmers for their first moderator. He thus necessarily vacated his chair in the Edinburgh university, and the subsequent 4 years of his life were spent in effecting the organization and stability of the new church, in performing his duties as prin- cipal of the Free Church college which had been founded by its adherents, and in writing for the "North British Review," which was start- ed under his superintendence. Never was his statesmanlike and indefatigable character more conspicuously displayed than in his conduct of the movement which led to the erection of the Free church, and of the proceedings by which that church was securely established. He had but just returned from London, which he had visited for the purpose of enlisting the principal statesmen in support of his views on national education, when in the morning he was found dead in his bed, with the utmost tranquillity of feature and without sign of pain or struggle. The collected writings of Dr. Chalmers form 84 large 12mo. volumes, and in them all the problems which most strongly agitated the public, and especially the religious community, in his time are discussed. They embrace also lectures and commentaries on portions of the Scriptures. Yet the most important results of his life are not contained in his books, but appear rather in the ardor and energy which, whether as preacher or teacher, he com- municated to all with whom he came in con- tact, and in the important social and eccle-

siastical reforms which he inaugurated. Both as a preacher and thinker he dwelt on the broadest and cardinal views of things. Many of his sermons were said to contain not more than one or two ideas, around which his mind would revolve as on a pivot, presenting the same object in a series of new and beautiful forms. He always retained his broad Scotch accent, and his vehement and chivalrous resolution and philosophic temper were mingled with a guileless simplicity and a profound sympathy with the habits and feelings of the Scottish poorer classes.

CHÂLON-SUR-SAÔNE, a town of France, department of Saône et Loire (Burgundy), on the river Saône, 215 m. S. E. of Paris; pop. in 1856, 19,911. The town is very ancient, being the Cabillonum of which Cæsar speaks in his Commentaries. It was pillaged by the Vandals, the Huns, and the Saracens, burned in 834 by the emperor Lothaire I., suffered severely during the civil wars of the 16th century, and not a little from the invasion of the allies in 1814. It is at the head of navigation on the river Saône, and is one of the principal stations of the Paris-Lyons-Marseilles railroad.

CHÂLONS-SUR-MARNE, a city of France, on the river Marne (Champagne), 107 m. E. of Paris; pop. in 1856, 16,551. It was an important place when the Romans invaded Gaul, and was known as Duro-Catalaunum. Here in 274 the emperor Aurelian defeated Tetricus, his competitor. In its vicinity, probably between the villages of La Cheppe and Cuperly, was fought in 451 the tremendous battle in which the Romans under Aëtius, the Visigoths, the Burgundians, and the Franks united to oppose Attila. During the middle ages it numbered 60,000 inhabitants. During the civil wars of the 16th century, it burned the bulls of excommunication hurled against Henry IV. by Popes Gregory XIV. and Clement VIII. Châlons is the seat of a bishopric; beside a college, it contains several learned institutions, the most important of which is the school of arts and trades, where 450 pupils are maintained at the expense of the government. There are factories of coarse woollen stuffs and cotton hosiery.

CHALOTAIS, LOUIS RENÉ DE CARADECO DE LA, or LA CHALOTAIS, attorney-general at the parliament of Rennes, born there in 1701, died in 1785, struck the first blow at the Jesuits in France by publishing, in 1761, *Le compte rendu des constitutions des Jésuites*. In 1765 he was arrested for having, in common with other members of the Breton parliament, refused to vote in favor of some financial measures of the government. The persecution to which he was then subjected was attributed to the hostility produced by his action against the Jesuits. While in prison he wrote an eloquent and vindictory memoir, and in the absence of writing materials, used a toothpick as a pen, and soot diluted in vinegar and sugared water as ink.

CHALUS, a small town of France, in the

department of Haute-Vienne (lim the Tardouère, 16 m. N. W. of St. pop. 2,200. It is divided by the river into upper and lower town, in the former of are the remains of the castle of Chabrol, besieging which Richard Cœur de Lion was fatally wounded in 1199. Near it is the ruined fortress of Montbrun.

CHALYBÆUS, HENRICH MONTZ, a philosopher of philosophy at the university of 1839, born July 3, 1796, at Pfaffroda, graduated in 1820 in the divinity at Leipsic, and officiated as private teacher professor at Vienna, Meissen, and until 1839, when, chiefly owing to the position established for him by his work "Historical Development of Speculative Philosophy, from Kant to Hegel" (Dresden, 1838), he received his present appointment at the university of Kiel. He has since published a variety of other writings, the most important of which is his "System of Speculative Philosophy" (Leipsic, 1850). A later work, entitled "Philosophy and Christianity," appeared in 1855.

CHALYBEATE (Gr. *χαλύψ*, steel, *bea*, a Scythian race that worked iron), a name now applied to waters and minerals which contain iron. It generally designates them in the state of the carbonate of iron oxide, which is soluble so long as carbonic acid is present; as this is exhausted, the protoxide absorbs oxygen, and is converted into an insoluble hydrated sesquioxide, which falls down as a yellow ochreous powder. Chalybeate waters possess a styptic taste, and give the characteristic reactions indicating the presence of iron by the addition of a solution of ferrocyanuret of potassium. In several springs that might claim this property, the most common. The most important of these are those of Bedford and Brandywine in England. Arsenic and copper are found in the sediment of chalybeate springs, but appear to do no harm, on account of the detoxicating properties of the oxide of iron.

CHAM, the pseudonym of AMÉLIE, a French caricaturist, born in Paris in 1819, who adopted the name Cham, one of the sons of Noah, his father being Noé (Noah). The son of a painter, he attended the polytechnic school; but, following his artistic inclinations, he became a painter, like Delaroche and Charlet, and has acquired distinction as a caricaturist by his humorous contributions to the Parisian press, and by the publication of several books of caricatures.

CHAMA (Gr. *χάμα*, to gape), a genus of lamellibranchiate bivalves of the family *Mytilidae*, which includes, moreover, *monopleura* and *diceras*, all of which have inequivalve shells, one of which has another 1 tooth; the foot is short, and the corresponding pedal orifice is small. The anterior muscles, they belong to the same class, and, like the kindred

iphons and are marked by a simple By Linnæus, Cuvier, and De Blainius was made of great importance, any shells now transferred to other the giant clam, *tridacna gigas*, was (see CLAM).

CHAMBERLAYNE, EDWARD, an English a at Odington in Gloucestershire, at Chelsea, a suburb of London, ducated at Oxford, he made the pe during the civil wars. In 1679 nted tutor to Henry, duke of Graf- son of Charles II., and afterward eorge of Denmark, the husband nne. He is best known by his titiæ, or the Present State of Eng- rich the first edition appeared in lay in his history makes frequent this book.

CHAMBERLEN, HUGH, an English phy- in 1664, died June 17, 1728, was a Cambridge, where he obtained his D. in 1690. The invention of an eps is commonly attributed to him, father, Dr. Paul Chamberlen, is ave been the real inventor.

CHAMBERS, an E. co. of Ala., bordering on Georgia; area, 775 sq. m.; pop. in 1850, 28,960, of whom 11,158 were slaves. It is partly bounded on the E. by the Chattahoochee river, and intersected by the Tallapoosa. The surface is hilly, and most of the land productive, hav- ing yielded, in 1850, 17,442 bales of cotton, 876,088 bushels of corn, 166,075 of sweet pota- toes, and 118,962 of oats. There were 41 churches in the county, and 1,466 pupils at- tending public schools. Capital, Chambers Court House.

CHAMBERS, EPHRAIM, an English cyclo- pædist, born at Kendal, in Westmoreland, died at Islington, May 15, 1740. The son of a Pres- byterian freeholder, he received a commercial education, and formed the project of the cyclo- pædia which bears his name while apprenticed to a globe-maker in London. Some of the arti- cles are said to have been written while he tended his master's counter. The 1st edition of his "Cyclopædia" was published by subscrip- tion in 1728, in 2 vols. folio; the 2d en- larged edition in 1738, and the 3d in the fol- lowing year. This work was avowedly the basis of the more extended cyclopædia of Rees, and was early translated into the French and Italian languages.

CHAMBERS, GEORGE, an English artist, born near the end of the last century at Whitby, in Yorkshire, died in London, Oct. 28, 1840. The son of a poor seaman, at the age of 10 years he sailed in a trading vessel as cabin-boy, and was soon noted among his messmates for his rude sketches of ships and marine views. With the determination to become a marine painter, he left the service, and after 8 years' private prac- tice, during which he supported himself as a house-painter, he went to London, and was em- ployed by Mr. Horner for 7 years to assist in preparing the panorama of London exhibited in the Colosseum. He afterward obtained com- missions for marine sketches from many dis- tinguished persons, and painted the "Opening of New London Bridge" for King William IV., and a view of "Greenwich Hospital" for Queen Adelaide. His appointment as marine painter to their majesties had opened to him a way to fame and fortune, when his delicate physical constitution failed him. His works, several of which are naval battle-scenes, are highly valued.

CHAMBERS, SIR WILLIAM, an English archi- tect, born of a British family at Stockholm, in Sweden, in 1726, died in London, March 8, 1796. He was educated at Ripon, in Yorkshire, and while very young went as supercargo to the East Indies, resided for some time in China, and brought back many drawings of Chinese build- ings and costume, which were afterward pub- lished. He then devoted himself to the study of architecture, and on returning from travels in France and Italy was appointed drawing master to the prince of Wales, afterward George III. He laid out the royal gardens at Kew in the Chinese style, and built the villa of the earl of Besborough at Roehampton, in the Italian

ceeded to an Edinburgh printer, while Robert, failing to get the collegiate education which he had desired, entered upon the career of bookseller on his own account. Until 1882 the brothers conducted separate establishments, and their struggles during the period when the yet anonymous Waverley novels, the criticisms of Jeffrey, and the sketches of Christopher North were distinguishing Edinburgh as a literary centre, are eminent examples of energy and diligence. William eked out the profits of a small trade by working at case and press himself, and in 1880 published his "Book of Scotland," an elaborate and comprehensive account of the usages and institutions, the schools, social system, and religious and civil organization of that country. Meantime Robert, sharing in the enthusiasm which was then introducing the national element so largely into Scottish literature, had published in 1824 his "Traditions of Edinburgh," an authentic, detailed, and amusing account of the old memories and associations with which the various localities of that capital are rich. It was dedicated to Sir Walter Scott, who had communicated to him interesting materials for it. This was rapidly followed by his "Popular Rhymes of Scotland." "Pictura

, a village, pop. about 400, in artment of Loire-et-Cher, 9 m. is noted for a château of its ounded by a beautiful park, 21 nce. The counts of Blois had edge and pleasure house built added to the possessions of the

crown by Louis XII., and torn down by Francis I. to make way for the present magnificent structure, which was commenced in 1526, after designs by Primaticcio. For 12 years Francis prosecuted the work with great vigor, and died leaving it unfinished and his treasury half empty. It was continued with less activity by Henry II., Charles IX., Henry III., Louis XIII., and Louis XIV., but the original plans were never carried out. The style of architecture, which marks the transition from the fortified castle to the Italian palace, is a fine specimen of the prevailing taste of the 16th century, and though fantastic in some details, is, on the whole, grand and imposing. The material is a very dark stone. From a solid basement, flanked by 6 round towers, each 60 feet in diameter, rise clusters of pyramids, cones, and turrets, with a large central tower crowned with a beautiful lantern, on which is a stone figure 8 feet high of the lily of France. This tower contains a double spiral staircase, so curiously contrived that persons ascending never meet those descending. There are 440 chambers, once decorated by the pencil of Cousin and the chisels of Bontemps, Goujon, and Pilon. The stables have stalls for 1,200 horses.—The early history of Chambord is little more than a chronicle of royal debaucheries. Built, it is said, to commemorate the passion of Francis for the countess de Thoury and the fair châteline de Montfrault, and exhibiting in the form of caryatides the features of 2 of his other mistresses, the duchess d'Étampes and the countess de Châteaubriant, it preserved its character under several succeeding reigns. It was here that the beautiful but faithless Diana of Poitiers achieved more than one of her conquests, and the letters H. and D. entwined with a crescent, which still fill the compartments of the vaulted ceilings, attest her ascendancy over Henry II. Charles IX., Louis XIII., and Louis XIV. held their court here with equal licentiousness and splendor; and at a fête given by the last named monarch in 1690, one of the grand corridors was converted into a theatre, in which Molière gave the first representation of his *Bourgeois gentilhomme*. Chambord afterward became the residence for 9 years of Stanislas Leszczyński, king of Poland. In 1745, Louis XV. bestowed it upon Marshal Saxe, who restored much of its former brilliancy and lived there in military state, attended by 2 regiments of his lancers. After his death, and that of his nephew the count de Frise, the château reverted to the crown; it was bestowed upon the Polignac family by Louis XVI. in 1777, plundered by the mob in 1792, and sold as national property. Napoleon gave it to Marshal Berthier in 1809, from whose widow it was purchased by the loyalists in 1821, and presented in the name of the nation to the duke of Bordeaux.

CHAMBORD, HENRI CHARLES FERDINAND MARIE DIEUDONNÉ D'ARTOIS, count of, born in Paris, Sept. 29, 1820, the only son of the duke of Berry, and therefore the last remaining scion

was published in England, in the name of the duke of Orleans, against the authenticity of an event by which he seemed to have lost a crown. True, the alleged author affected to deny, with a virtuous indignation, any complicity in the publication; but when the document was reprinted after the revolution of 1830, he did not choose to contradict it again, and some doubt may be entertained as to the sincerity of his first denial. The royal child was hardly 10 years old when the revolution of 1830 drove the Bourbons, now for the 3d time, out of France. Charles X. having abdicated, Aug. 2, 1830, and the duke of Angoulême having abandoned his right of succession in favor of the young prince, the latter was constrained to follow the exile of his family. The title of duke of Bordeaux had been given him at his birth, as an acknowledgment of the devotion by which the city of Bordeaux had distinguished itself in 1814 in favor of the cause of the Bourbons. The young exile now changed it for one more appropriate to his present fortune, and henceforth assumed the name of count of Chambord, from the castle and domain of Chambord, presented to him May 21, 1831, by public subscription in France, and still his property.

public commotions, and that the government which the revolution of July cost the legitimists, and notwithstanding the duties inherent in its original position toward the dynasty of the Bourbons had played a game. However, this position was without strong opposition. Many among the men then called *Henricquists* had a different interest of their cause. They took the oath, and participated in public affairs. Some induced and solicited the legislature to the chamber of deputies to vote consistently with the opposition successive cabinets—the one given for years by the legitimists some unsuccessful attempts in Vendée and Brittany. In fact, broken up by internal dissensions, the count went to Italy, with his received with great distinction XVI. After the death of Angoulême, in Jan. 1836, the

been otherwise prevented from tribute of their homage to their prince; and for some time, the cap- itish empire was peacefully invaded adherents to the principle of legit- evoted partisans of its representa- members of the chamber of dep- at consider it irreconcilable with play a prominent part in this man- inst the established government The majority of their colleagues rwise; and after an animated and iscussion, censure was inflicted on t by the address of the chamber in he speech from the crown. The puties appealed from the judgment s to the decision of their constit-

ined them by a reëlection, and soon subsided, without any great amage to any body. On Nov. 16, unt of Chambord married Maria ice Gaëtana, princess of Modena, , 1817, and therefore 8 years older . This union has remained sterile, ring been born of it to save the use from annihilation. It seems, Providence had doomed to destruc- y party which invokes most tena- exclusively the protection of its

The political inheritance of the destined to pass to the young count grandson of Louis Philippe, whom ts regard as a usurper.—After the is Philippe in exile, the community e suggested to the vanquished on e idea of a reconciliation between s of the two royal families. Some anted; messages and visits were and some interested politicians ex- ; they considered already a decisive a better state of things. Indeed, Chambord seemed decided to take asure toward regaining the crown

When an opportunity, apparently ble, had presented itself after the of June, 1848, in Paris—and later, agitations and disquietudes of the e inactive pretender had let pass which another claimant took ad- boldly to build up an imperial was against this intrusive interest, ork for the foundation of a new t the political fusion of the two the Bourbon family was aimed. ed by the decided opposition of the Orleans, whose influence with her amount. Faithful to the memory d, the noble widow conformed her- structions of the duke of Orleans, itten in his last will: "Whether a nknown and obscure defender of a ch we all belong, the count of Paris e everything, to be a man of his he nation—a Catholic, and the pas- sive servant of France and the How and on what terms the pas-

sionate and exclusive servant of the revolution could join in a common cause with the repre- sentative of the principle of legitimacy, irre- spective of the popular sanction, it was impos- sible to understand. Some other obstacles also arose from delicate questions started in the dis- cussion of a common political platform. The royal cousins could not agree, nor their coun- sellors, on the adoption of an intended national flag, the one party advocating the white ban- ner, the other standing by the tri-color. So the proposed scheme was abandoned after some useless efforts, based more on common interest than on mutual sympathy.—The count of Cham- bord resides alternately in Venice, where he owns the beautiful Cavalli palace, and in the castle of Frohadorf, near Vienna. In the sum- mer he is accustomed to repair to some water- ing place, like Ems, Wiesbaden, &c., in the neigh- borhood of France, where he receives the disin- terested respects of numbers of his faithful parti- sans, who are delighted with his affable and grace- ful reception, and charmed with the happy qual- ities which he possesses as a man. Were it not for certain unfortunate influences which have constantly surrounded and still surround him, his natural gifts would have shown more ad- vantageously; as it is, through the delusions of his present life, and the ordeal of contemporary events, each passing day is more likely to leave with him a new regret than to bring him a new hope.—Physically the count of Chambord is rather below medium stature, with a short neck, broad shoulders, and a full chest, conveying the impression of strength rather than of dignity. At the age of about 15 years, he had a severe fall from his horse, from the lameness caused by which he has never entirely recovered. He is nevertheless very fond of manly sports, and pursues them in a princely manner. His fea- tures are handsome, of the Bourbon type, with blue eyes, light hair, mustache, and whiskers. His fortune, which was originally large, has been much increased by his marriage with one of the richest princesses of Europe, and by the inheritance of the duchess of Angoulême, from whom he received the estate of Frohadorf, which belonged originally to the duke of Blacas.

CHAMBREY, GEORGES DE, marquis de, a French general, born in Paris in 1788, died about 1850, served in the Napoleonic wars, fell into the power of the Russians, was banished to the Ukraine, and not permitted to return to France until after the fall of Napoleon. From 1828 to 1829, he filled high military positions at Vincennes and Perpignan. He wrote vari- ous works on military subjects. A 2d edition of his *Philosophie de la guerre* appeared in 1885, and a "Life of Vauban," written by him, ap- peared in the *Plutarque Français*. His most im- portant production is his *Histoire de l'expédition de Russie*, which appeared in 1887, and has since passed through several editions.

CHAMBRE ARDENTE. Originally this name was applied in France to courts of law, hung with black, but lighted by torches, where criminals

parcels, one of 2 and the other of 3, each united by the skin as far as the claws. The tongue is fleshy, cylindrical, and capable of an elongation of 6 or 7 inches; the teeth are trilobed; the eyes are large, almost covered by the skin, except a small hole opposite the pupil, and are capable of movements independent of each other. The back of the head is raised in a pyramidal form; there is no visible external ear; the first rib is united to the breast-bone, the rest being continued to their fellows of the opposite side, enclosing the abdomen in an entire circle. The lungs are large and admit of great inflation. The most common species is the *chameleo vulgaris* (Lac.), so well known to travellers in Egypt and northern Africa. Many other species are described from the Sechelles islands, Isle of Bourbon, Isle of France, and Cape of Good Hope. The chameleon is well described by Aristotle in his "History of Animals." The name is derived from the Greek, and signifies little lion, or, as some maintain, camel lion. There is probably no animal about which more prejudices and errors have existed from the remotest antiquity than the chameleon. The 2 most remarkable faculties attributed to it are those of being able to

often seen of the same color as the objects, which they doubtless use as a means of protection against numerous enemies. The chameleon can inflate its body, even to its bursting, by its slow and irregular motions; to a certain degree may aid the muscular action of the skin in the production of its face changes. The chameleon moves very slowly; it will remain for days upon a tree, to which it fixes itself by means of its peculiarly divided tail. This slowness of motion is a consequence of its want of sense of all defensive and offensive means, which render them an easy prey to their enemies. Whether upon a tree or on the ground, it is the most disagreeable and awkward of animals. Native Africans and Asiatics have considered the chameleon a harmless creature, and have used them in their dwellings on account of the insect pests they destroy. When they are very gentle, but they are very slow with each other, slowly opening and closing their jaws, like the blades of a scissor, in a ludicrous manner. The female deposits a dozen eggs, which she deposits in a hole, leaving them to be hatched by

CHAMIER, FREDERIC, an English novelist, born in London in 1796. His forte lies in sea stories of the Marryat school. The most popular of his works are "Ben Brace," "The Arethusa," "Trevor Hastings," "Passion and Principle."

CHAMISSO, ADELBERT VON (LOUIS CHARLES ADELAIDE DE CHAMISSO DE BONCOURT), a German author, born Jan. 27, 1781, at the château of Boncourt, Champagne, France, died in Berlin, Aug. 21, 1838. At 9 years of age he accompanied his family to Berlin, and entered the Prussian army as lieutenant in 1798, but left it in 1806. He returned to France and devoted himself to the study of natural history, his acquaintance with Madame de Staël and her learned circle having turned his attention in that direction. From 1815 to 1818 he accompanied the expedition set on foot by Count Romanzoff in a voyage of discovery around the globe. On his return to Berlin he received an appointment at the botanical garden. He published 2 botanical works, and 2 works connected with his journey round the world, also a treatise on the Hawaiian language. In conjunction with Gaudy he translated a selection of Béranger's songs into German. Many of his lyrical productions appeared in the *Musenalmanach*, which he and Varnhagen von Ense edited from 1804 to 1806. His literary reputation in Germany rests more upon his lyrical poems, which take up one-third of the 6 volumes of his collected works. Out of Germany he is principally known as the author of "Peter Schlemihl"—the story of a man who had lost his shadow. This book was published in 1814, through the agency of his friend Fouqué, and passed through many editions.

CHAMOIS, or GEMS (*antilope rupicapra*, Pallas), the mountain or Alpine antelope of Europe, and the only animal of that geographical division which partakes in any degree of the character of the antelopes. It is found in the Pyrénées, the Alps, the Carpathian and Grecian mountains, the ranges of Caucasus and Taurus, the heights of the Himalayas, and perhaps in other situations of similar character. The chamois is rather more than 8 feet in length, and a little above 2 feet in height. Its smooth black horns are about 6 inches long, rising nearly perpendicularly from the fore part of the brow, abruptly hooked backward at their extremities, and nearly parallel through their entire extent. It is beardless, but the body is covered with a short thick fleece of fine wool, to protect the animal from cold, and also with long and silky hair of a deep brown color in winter, brown fawn color in summer, and slightly mixed with gray in spring. The head is silvery yellow, the inside of the thighs and ears white, and the tail black. A small black band winds from the corner of the mouth around each eye. The kids are of a deep yellow color. Impatient of heat, the chamois remains in the summer on the loftiest ridges, or in snowy valleys, clipping for its food

the mountain herbs and the tender shoots of shrubs, and rarely drinking. It is remarkable for its agility, and for its keenness of sight and smell. It scents a man at a long distance, is at once thrown into great agitation, and flies at its utmost speed on his first appearance. It bounds from rock to rock with an admirable grace, and ascends and descends cliffs which few other animals would attempt. It is more closely allied to the prong-horn (*antilope Americana*) than to any other species of antelope. The structure and form of their horns are nearly similar; and the pelage of each of the two animals is peculiar, though not identical. It is, in some respects, a connecting link between the true antelopes and the goats, although far more closely allied to the former. The chamois is easily tamed, and becomes very familiar and fond of the persons who feed it. The venison is but moderately good, bearing some resemblance to that of the roebuck, but inferior in flavor and quality. The skin is dressed into a fine light leather, in use for undergarments, and for cleaning plate, glass, and the like; though but a small quantity of what is sold as chamois, or, as it is usually termed, shammy leather, is actually made from the hide of this animal.—Of all sports, the pursuit of the chamois is the most difficult and perilous. Even the trade of the samphire gatherer, or that of the egg plunderer of the Hebrides and Orkneys, sinks into insignificance and tameness beside that of the chamois hunter, amid the interminable and awful solitudes of the upper Alps. Of all sports, also, it is the least profitable, so rare is the beast becoming even in his most difficult and remotest haunts, so small, comparatively, are the chances of success, and so little the value of the game when taken.

CHAMOMILE (Gr. *χαμαι*, on the ground, and *μηλον*, apple; *anthemis nobilis*, Linn.), a plant indigenous in the south of England, and widely cultivated in gardens for medical use. Its leaves and daisy-like flowers emit a strong perfume when trodden upon. The flowers have long been famous as an aromatic bitter. A tepid infusion of them, known as chamomile tea, is often employed as an emetic. They are used externally as fomentations in colic and intestinal inflammation. Chamomile is naturalized in many parts of Europe, and in the state of Delaware.

CHAMORRO, FRUTO, a soldier and statesman of Central America, born in the city of Guatemala in 1806, died March 12, 1855. He belonged to one of the oldest and most wealthy Nicaraguan Spanish families. In 1823, when a student at the university, he fought as a volunteer against the insurgent soldiers, who were endangering the first national constituent assembly. His public life began in 1836 as a representative to the legislature of Nicaragua. As a member of the constituent assembly, which met in 1838 for the reform of the organic law, he aided in establishing the oriental university at Granada. He was elected, under the

and the recommendation of Chamorro that this item be reduced produced discontent on the part of the soldiers. He sought to secure the harmony of the ministry by resigning his place; but (Aug. 4, 1851) a rebellion broke out, which ended in the expatriation of Pineda. The legislative chambers at Managua immediately elected Chamorro general-in-chief, with powers to collect a force and march upon the malcontents. The revolutionary attempt was chiefly supported by Gen. Muñoz, who was obliged after one victory to surrender with his officers and men to Gen. Lope, by whom they were transferred to Gen. Chamorro. Though exposed to the penalties of treason, the safe conduct which was guaranteed to them at their capitulation was respected, and they were permitted to leave the state. In 1853, Gen. Chamorro was chosen to succeed Pineda as supreme director, and he strengthened public credit by his plans of reform. A conspiracy was detected in 1854, and the conspirators, having taken refuge in Honduras, soon invaded Nicaragua with a large force from that country. They were met by President Chamorro, who was defeated and obliged to fall back upon Granada. There he was besieged 981 days when the insurgent

occasion is made a holiday on the other side of the g cattle till autumn. The se ever since public attention 1741 by the English travel Pocock, has attracted thou ery season. **uni**, or La Prieuré. The village is supported **ly** by tourists, to whom it presents many **tions** and conveniences.

**CHAMP DE MARS**, the name given to the **ual** meetings held by the Frankish tribes, **took** possession of Gaul during the 5th **ury**. They were called in Latin *Placita*, **le** the Frankish appellation was *Mals*. These **etings** were sometimes military reviews, or **em** national assemblies, where all the free-**n** among the Franks gathered to pay homage **the** supreme chief of the nation; sometimes **cial** assemblies of the lords and warriors, **led** by the king to consult upon some mili-**r** expedition, or of the bishops, to take their **ice** upon some point of general policy and **ast** some interior difficulty. Under the first **ovingians**, the time of these meetings was **anged** from March to May, whence they were **led** *Champ de Mai*.—**CHAMP DE MARS** is also **name** of an immense oblong square, situated **the** outskirts of Paris, between the *école mili-  
taire* and the Seine, and especially devoted to **the** drilling of troops and those great military **pageants** which the French are so fond of. It **is** 8,280 feet long by 1,640 wide, is flanked by **ditches** faced with stone, has 4 rows of trees **on** each side, and is entered by 5 gates. The **first** great feast of the French revolution, the *fête de la fédération*, was celebrated here. On **that** occasion, the place not being ready, the **population** of Paris, of both sexes and all ranks, **went** to work by night and day, and completed **it** by the day, July 14, 1790. The following **year**, the place was the scene of a dreadful **massacre** ordered by the leaders of the consti-**tutional** party. In 1793, the accepting of the **Constitutional** act voted by the convention; in **1794**, the feast of the Supreme Being, with **Robespierre** as its leading performer; in 1796, **the** rejoicings on account of the taking of Milan **by** Bonaparte, took place there. On June 1, **1815**, Napoleon held there the great assembly, **known** as the *Champ de Mai*, for the acceptance **of** the supplementary act to the imperial con-**stitution**. Here in 1827 the review was held, **in** consequence of which the Paris national **guards** were disbanded by Charles X. The re-**publican** feast of agriculture and industry was **celebrated** there in 1848.

**CHAMPAGNE**, an ancient province of France, which, previous to the revolution, con-**stituted** one of the great general military gov-**ernments** of the country, and was divided into **8** principal districts, viz.: Champagne proper, **Le Rémois**, **Le Rethelois**, **La Brie-Champenoise**, **Le Perthois**, **Le Vallage**, **Le Bassigny**, and **Le Sénonais**. For a long time it was governed by **native** princes, and was united to the crown of **France** at the beginning of the 14th century. At present Champagne is distributed among the **departments** of Aube, Marne, Haute-Marne, Ar-**dennes**, and part of the departments of Seine-et-**Marne**, Aisne, Yonne, and Meuse. Now, as then, **Champagne** is chiefly celebrated for its wines. It contains in all about 52,437 hectares or 125,-

000 acres of vine-growing land. That of the **present** department of Marne, however, alone **produces** what is technically known in com-**merce** as champagne wine. The department **of** Ardennes, which occupies the northern part **of** the province, produces, in average seasons, **about** 80,000 hectolitres, or 1,760,000 gallons **of** a common red wine, which is exclusively **consumed** by the inhabitants. The best of **it** is wanting in body, spirit, and color, and **will** not bear exportation or keeping. The **department** of Haute-Marne, in the south-**ern** portion of the province, produces about **600,000** hectolitres, or 13,200,000 gallons, **of** which about one-half is consumed in the **department**, the remainder being sold to the **neighboring** arrondissements. The quality of **the** wines is superior to those of Ardennes **in** delicacy, flavor, and hardiness. The de-**partment** of Aube, which forms the S. E. por-**tion** of the province of Champagne, and the **N. E.** portion of that of Burgundy, yields **about** 580,000 hectolitres, or 12,500,000 gal-**lons** of red wine, the larger portion of which **is** reserved for home consumption, the rest **finding** a market as *vin ordinaire*. The better **classes** of wine are strong-bodied and heady, **requiring** to be kept at least 2 years before **they** are fit for use. Some white wines are **also** produced in this department, which are **highly** esteemed for their lively, spirituous, **and** agreeable qualities. The department of **Marne**, which forms the most important portion **of** the province, geographically as well as com-**mercially**, has about 20,000 hectares, or 46,000 **acres** of vineyards, which are divided among **27,000** different proprietors, and yield on the **average** about 700,000 hectolitres of red and **white** wines, one-third of which, principally the **former**, is consumed within the department, **the** balance forming one of the great staples **of** the commerce of the district. This department **is** divided into 5 arrondissements, viz., Châlons-**sur-Marne**, Épernay, Rheims, Sainte Ménéhould, **and** Vitry-sur-Marne, of which Rheims and **Épernay** contain the most celebrated vineyards. **The** vines most in vogue are: for red wines, *le petit plant doré*, *le pineau*, *le perlusot*, and *le couleux*; for white wines, *le blanc doré*, *le petit blanc*, *le chasselas*, and *le gros plant vert*. **White** and black varieties of grape are culti-**vated** indiscriminately in vineyards destined **to** furnish white wines, the mixture being **deemed** necessary for the perfection of this **style** of wines, especially those denominated **sparkling**. In an exceedingly propitious sea-**son**, however, the black grapes are apt to im-**part** too much color to the liquor in the pro-**cess** of pressing; but as they produce still **and** creaming wines, superior in many neces-**sary** requisites to the white grapes, they are **more** generally employed, although great pre-**cautions** are required to prevent this from oc-**curing**, not only by choosing the healthiest and **ripest** grapes, but also by discarding all green, **dry**, and spoiled berries.—When the vintage

sediment, which, after being thoroughly commingled and amalgamated, is allowed to settle, and is then drawn off into bottles, which are placed in racks so constructed that each bottle can be raised or lowered, so as to lie perfectly flat, or stand almost perpendicular. Up to this moment, the wines are rarely tampered with by the introduction of either sugar or brandy, but, in adverse seasons, those substances are sometimes necessary to enable them to undergo the operation of a secondary fermentation, without which it is impossible to make them sparkle or *mousser*. This process ordinarily commences during the month of June, and continues the whole summer, pending which, especially when the grapes begin to ripen, or in stormy weather, immense loss is sustained by the bursting of the bottles, and the consequent escape of the liquor. After a lapse of 18 months, during which the carbonic acid gas is generated by means of the suppressed fermentation, a thick muddy deposit is precipitated to the neck of the bottle, which has gradually been raised to a standing position, and the wine becomes perfectly clear and limpid, having a very light straw color, and in this state it will remain unchanged for years. When required for exporta-

tion, it is sometimes somewhat less white. This beverage, although factitious, occupies a higher place in popular regard than is justly esteemed by the anatomist, and the refined epicure. Its qualities are agreeable sweet, and its diuretic and strengthening rendering it valuable to the first; its full flavor, delightful aromatic bouquet, endearing it to the taste. At Rheims, the business center, it varies from 2 to 5 francs per bottle, including the duty; and in the west the maximum price has rarely

**CHAMPAGNE**, or **CHAMPAGNE**, a Flemish painter, born in 1602, died in Paris, Aug. 12, 1692. He came to Paris at the age of 18, having enjoyed the instruction of his father, yet acquired reputation for his portraits and coloring is excellent, and his great merit. His best picture is at Vincennes, and in the church of St. Louis at Paris. One of his best is of himself, now in the Louvre.

**CHAMPAGNY** **JEAN** **HAN**

He received the department of foreign affairs, which he kept until 1811. He followed Napoleon in the campaign immortalized by the battle of Wagram, and contributed to the treaty of peace which had for its result the marriage of the conqueror with the archduchess Marie Louise. He proposed also the annexation of Holland, the Hanseatic towns, and the duchy of Brunswick to the French empire; but lost his portfolio in 1811, for having misunderstood his master's intentions toward Russia. Louis XVIII. made him a peer, but he adhered to Napoleon during the Hundred Days, and was dismissed after the battle of Waterloo. In 1819 he was made a peer again; in 1830 he adhered to the government of Louis Philippe.

OHAMPAIGN. I. A W. central co. of Ohio, intersected by Mad river, and traversed by two railroads; area about 890 sq. m.; pop. in 1850, 19,762. The surface is level or undulating, and the soil fertile. Productions in 1850: 964,617 bushels of corn, 225,808 of wheat, 170,997 of oats, and 11,870 tons of hay. There were 84 churches, and 4,780 pupils attending public schools. Capital, Urbanna. II. An E. co. of Ill., area about 380 sq. m., comprising a part of the Grand Prairie; pop. in 1855, 6,565. The surface consists of an open plain of great fertility, interspersed with small clusters of trees. The productions in 1850 amounted to 441,060 bushels of corn, 38,850 of oats, 1,406 tons of hay, and 53,710 lbs. of butter. Capital, Urbanna.

CHAMPE, JOHN, an officer in the war of the American revolution who gained distinction by his efforts to seize Arnold after his treason, born in Loudon co., Va., in 1752, died in Ky. near the close of the 18th century. He was selected from Gen. Lee's regiment by request of Washington, to go to New York as a deserter and spy, and if possible to seize and bring off Arnold in time to save the life of André. Champe undertook the enterprise with courage, passed the American lines with difficulty, was hotly pursued by his comrades as a deserter, reached New York, underwent an examination before Sir Henry Clinton, and by him was consigned to Gen. Arnold, who gave him in the British army his former rank. He discovered the custom of Arnold to walk in his garden at a late hour every night, formed a plan with a comrade to seize and gag him there, and to take him between them as a drunken companion to a boat on the Hudson, whence arrangements were made for his speedy transportation to the American head-quarters. On the appointed night Arnold failed to appear in the garden, and Champe after waiting for him till near morning returned with deep chagrin to his position in the British army. It proved that Arnold had the day before changed his quarters, preparatory to the embarkation of his troops for Virginia. There was nothing left for Champe but to embrace the first opportunity to escape to the American army, which he did soon after landing in Virginia, and joined the troops under Gen. Greene. Gen. Washington discharged him from

further service, lest, falling into the hands of the enemy, he should be immediately put to death upon a gibbet. When subsequently Washington sought for him to reward him for his faithful and dangerous service, he learned of his recent death in Kentucky.

OHAMPERTY (*campi partitio*), an agreement to divide land which is the subject of a suit, or the title to which is involved in controversy, in consideration of which the suit is to be carried on by the person who makes the bargain with the owner or claimant of the land. The term, however, is now applied to any suit, whether relating to real or personal estate, and champerty may be defined to be any agreement for the division of what shall be realized from a suit, in consideration of services to be rendered or money advanced on account thereof. In a popular sense it also includes the purchase of lands from a claimant who is not in possession, and the purchase of choses in action, for the purpose of bringing suit upon them, though neither of the two latter cases is strictly what is designated etymologically by the word; there being in fact no division of the subject, but a mere purchase on speculation. Maintenance was the aiding another in the prosecution of a suit, and if it was in consideration of receiving a part of what should be recovered, it constituted champerty. The distinction between maintenance and champerty was, that maintenance was the aiding or abetting the prosecution of a suit, whether for a part of the thing in suit or not; if a part of what should be recovered was to be received by the person aiding in the prosecution, then it was champerty. By old English statutes it was forbidden to aid a party to a suit in the prosecution or defence of the same, or to purchase a suit, or the right of suing. It was, however, permitted to aid a near kinsman, servant, or poor neighbor, from the mere consideration of relationship or charity. The evils sought to be remedied were: 1, officious intermeddling with controversies for the sake of some gain to be derived therefrom; 2, aiding a party from some motive of hostility or ill feeling toward the opposite party. At a time when the administration of justice was somewhat loose, and the minds of judges and juries could be acted upon by the influence of persons of some consideration, such interference with suits in aid of either party was a vicious abuse, and was by law declared to be a misdemeanor. As to the getting hold of claims to prosecute, whether by purchase or with an agreement to divide, it seems to have been practised by attorneys; and in addition to the general prohibition of maintenance, there was a special provision applying to attorneys. Then as to claims to land by persons out of possession, it was by statute prescribed that no one should buy or sell unless the vendor had been in possession or received the rents a year previous. Similar prohibitory laws have been generally adopted in this country, and in some states, as in Massachusetts,

where there was no statute on the subject, champerty has been held to be an offence at common law. In the state of New York an innovation was first made by allowing a person claiming title to lands, possession of which was held adversely, to execute a mortgage of such lands, which would be valid and have preference over all subsequent judgments against, or mortgages, &c., executed by the mortgager, in case he should ultimately recover title. The courts of that state have also made an exception as to conveyances of lands held adversely, if such conveyance was in pursuance of a contract entered into before the adverse possession commenced. Lastly, in respect to attorneys, the code of practice of New York authorizes a bargain between attorney and client as to compensation for the prosecution or defence of a suit, and this is understood to warrant an agreement that the attorney shall have part of what shall be recovered. It was a very ancient rule of the common law that choses in action should not be assigned, the object of which rule was to prevent any champertious intermeddling with claims to be put in suit; but courts of equity long since recognized the right of the assignee, and no other effect of the rule remained except that it was required that a suit at law should be brought in the name of the assignor. But this has now been abrogated in the state of New York, as well as many other states, and a suit must be brought in the name of the real party in interest.

CHAMPION, a term derived from chivalry, and signifying one who undertakes to defend his cause by force of arms. Custom allows a wider latitude of application to the word. In the ruder stages of society, when might constituted right, the right was frequently submitted to such an arbitrament. The two elements which then chiefly entered into the social system, namely, religion and love of military glory, both inclined toward a ceremony in which God should be called to indicate the righteousness of the cause by success in the trial by battle. Accordingly, we find from the earliest ages of feudalism the trial by private combat recognized as a legal mode of settling disputes. The trial came gradually to be hedged in by formalities, until it was only appealed to in cases of grave import. It is obvious that in many cases of personal encounter the disputants must be so unequally matched that they could not be pitted against each other with any chance of a fair result; the law therefore permitted the plaintiff, or the defendant in cases of accusation, to name a proxy or champion. Appeal to combat could be made in court-martial, that is to say, in cases coming under the jurisdiction of the court of chivalry or honor, in appeals of felony, and in certain cases upon issue joined in a writ of right. Ladies and minors, being disqualified by reason of their physical incapacity, prosecuted their claims by a champion. The champion usually challenged his opponent by casting down his glove, which the latter

accepted by taking up. joined, and carried on to be stopped by the judge. Ve for the victorious party. It tom that our modern phrase appeal to the God of battles." appears to be of Gothic o Norman introduced it it was practised as late as 11 year of Queen Elizabeth a trial of fought by champions in Tothil ster, on a writ of right. The pressed in France by St. Lo remained unrepealed on the book to the time of George II., wayman escaped from justice by appeal to wager of battle. In until recently in use on the cor kings of England, a champion ously. The championship of tary in the family of Dy male representative heir, style of the middle ages, and throwing down his to dispute the right of throne. This portion of occurred in 1821, at the coru IV. William IV. and Victor it.

CHAMPLAIN, a post village and township at the N. extremity of Clinton co., N. Y.; pop. of township in 1855, 6,197; of village, 1,471. It is situated on Chazy river, which supplies with water power, and is connected by the Northern railroad with Rouse's Point and Ogdensburg. It is comprised in Champlain collection district, and has some trade, which is carried on by the Chazy river. The village contains several churches, an academy, a newspaper office, and manufactories of iron and other articles.

CHAMPLAIN, a N. W. co. of Canada E. on the left bank of the St. Lawrence, traversed by the St. Maurice river, and including several small lakes; area 6,200 sq. m.; pop. in 1851-2, 13,896. In 1851-2 it produced 88,008 bushels of wheat, 200,796 of oats, 19,632 of buckwheat, 11,319 tons of hay, 5,469 pounds of tobacco, 29,130 of wool, 166,900 of maple sugar, and 81,059 of butter. It contained 8 grist, 11 saw, and 4 fulling mills, 1 tannery, 1 foundry, 13 schools, and 8 churches.

CHAMPLAIN, LAKE, a picturesque sheet of water lying between New York and Vermont, and extending from Whitehall, in the former state, to St. John's in Canada. It is 126 m. long, and varies in breadth from 40 rods to 15 m. Its greatest breadth unobstructed by islands is about 10 m., at a point near Burlington, Vt. Its depth varies from 54 to 262 feet, and vessels of 80 or 100 tons navigate its whole extent. The principal islands are North Hero, 11 by 2 m., South Hero, 18 by 4 m., and La Motte, 6 by 2 m.; these 3, with several smaller ones and the peninsula of Alburg, all in the N. part, form the county of Grand Isle in Ver-

The largest rivers entering the lake are the Otsego, Otsego or Winooski, Lamoille, Chazy, Saranac (the old Indian name for the lake itself), Au Sable, and the outlet of the lake in the S. W. part. Its own outlet is the Richelieu river, which empties into the St. Lawrence, and with the Chambly river forms a passage for vessels of large size into the ocean. On the S. it has boatable communication, by means of the Champlain canal, with the Hudson river. Navigation is usually open about the end of November, and closes early in April. The waters abound with pickerel, salmon trout, and other species of fish. This lake, filling a valley bounded by high mountains, is celebrated for its magnificent scenery, embracing the Green Mountains of Vermont on the E., and the Adirondack mountains of New York on the W. Several pleasant villages and watering places, with one or two important towns, are situated on its shores, which comprise the counties of Burlington and Champlain.

The tonnage enrolled and licensed in 1857, was 10,550 $\frac{2}{3}$ ; value of imports, \$2,965,582; value of exports, \$2,965,582; number of vessels entered, 1,878; tons, 122,548; number of vessels cleared, 1,758; tons, 117,836.

Champlain was discovered in 1609 by Samuel de Champlain, whose name it received. It has been the scene of many important events in the wars of the continent, and in the year 1759 it became of much importance in our war with the British. At that time an invasion of the northern portion of New York was contemplated, a force of from 10,000 to 15,000 troops being expected in the vicinity of Montreal for the purpose. In such an expedition, the command of Lake Champlain became an object of great importance, as it flanked the march of the British army for more than 100 miles, thus affording great facilities for the transportation of arms, equipments, supplies, &c. The efforts of the British were therefore directed to the creation of a naval force on the lake in the shortest time, and vessels were built and equipped with magical rapidity. The first, and the largest American vessel, was built at Plattsburg, and was launched on the 40th day of the first tree used in her frame was taken from the forest. In Aug. 1814, the English fleet, about 12,000 strong, commanded by Sir George Prevost, advanced in 4 divisions towards Plattsburg, then held by Brig. Gen. John C. Brown, with a force of only 1,500 men. Capt. M. McDonough, who commanded the American force on the lake, anchored in Plattsburg bay, Sept. 8, and awaited the appearance of the British squadron, which came down the river Saranac empties, at the mouth of the lake, and upon both its banks, stands the city of Plattsburg, which at that time contained about 70 houses. Cumberland head is the northernmost point of Plattsburg bay;

and about  $\frac{1}{2}$  of a league from it, in a S. W. direction, lies Orab island, small and low, and surrounded by an extensive shoal. Upon this island a battery of one gun was established. Capt. McDonough's vessels were anchored with springs on their cables in line parallel to the shore and in the following order: The Eagle, brig, of 20 guns (8 long 18s, 12 32-lb. carronades) and 150 men, Capt. Henley, was at the head of the line, and lay so near Cumberland head as to bring the enemy within carronade range should he attempt to enter the bay by doubling it; the Saratoga, ship, of 26 guns (8 long 24s, 6 42, and 12 32-lb. carronades) and 212 men, Capt. McDonough's vessel, was 2d; the Ticonderoga, schooner, of 17 guns (4 long 18s, 8 long 12s) and 110 men, Lieut.-commandant Stephen Cassin, was the 3d; and the Preble, a sloop or cutter, of 7 guns (long 9-pr.) and 80 men, Lieut.-commandant Budd, was the last vessel, lying so near the shoals off Orab island as to prevent the enemy from passing that end of the line. In addition to these 4 vessels, there were 6 gun-boats, mounting each a long 24-pr. and an 18-lb. Columbiad, and 4 of a smaller size, mounting each a long 24-pr. The complements of these gun-boats were about 85 men each. The total American force, therefore, was 14 vessels, mounting 86 guns, and carrying about 850 officers and men, including a small detachment of soldiers acting as marines. The gun-boats were distributed inshore of the large vessels, and in such a manner as to sustain the line the most effectually. They were not anchored, but were kept in motion by sweeps during the whole engagement. In addition to the customary arrangement of springs upon the cables, a kedge was laid off upon each bow of the Saratoga, their hawsers being brought in upon the quarters, the bights hanging under water out of the reach of shot. In the selection of his anchorage, and in all his arrangements for battle, Capt. McDonough evinced high professional ability, and to the precaution of laying out the kedges upon the quarters of his own ship, he owed the victory which ensued. On the morning of Sept. 11, 1814, just after the sun had risen, the approach of the British squadron was discovered by the guard-boats of the Americans, and preparations were made for action. Soon after 8 o'clock, the enemy having formed in line abreast, approached the American squadron in good order, the wind moderate and fair, the weather fine. The British squadron was commanded by Capt. Downie, an officer of distinction, and was composed as follows: The largest vessel, commanded by Capt. Downie in person, was the Confiance, a ship, of 37 guns, principally long 24s, with a complement of considerably more than 800 officers and men; the Linnet, brig, of 16 long 12s, with a crew of about 100 men; the Chubb, sloop, of 11 guns, 18-lb. carronades, and 1 long 6, and 40 men; the Finch, sloop, also of 11 guns, and 40 men; 12 gun-boats, 8 mounting 2, and the remainder 1 gun each;

ment, the whole starboard battery of the Saratoga had become unavailable, the long guns having been disabled by shot, and the carronades dismounted. It therefore became necessary to wind the ship, in order to bring the larboard battery to bear. This was accomplished by means of the kedges which had been laid out, and the fresh broadside was brought to bear upon the Confiance with great effect. She attempted the same evolution, though unsuccessfully, and, about 2½ hours after the engagement commenced, surrendered. The Saratoga's broadside was then sprung upon the Linnet, which struck a few minutes afterward. The Finch had previously been crippled, and drifted down upon Crab island, where, upon receiving a shot from the 1 gun battery, she surrendered; and the Chubb had earlier in the engagement struck to the Ticonderoga. The gun-boats struck soon after the Confiance, though they succeeded in escaping, none of our vessels being in a condition to pursue them. The American loss in killed and wounded was 111. That of the enemy was variously stated at from 173 to 204. The conduct of Capt. McDonough, his officers and men, was highly applauded; in fact, the calm and desperate bravery with which this action

from his patron De Chastee, decided de Montes. Letters patent to this nominated him vice-admiral, and lieutenant of his majesty in that part of the called Norimbergue, with full powers of peace and war, and to trade in ports 40° to 46° N., to the exclusion of all others, also to make grants of land. De Montes made a new engagement with the king for another voyage. Leaving Quebec they proceeded to the St. Lawrence, with a view of founding a settlement on its banks. De Montes finding the climate too severe, sailed the coast of Nova Scotia till they reached an island in the St. Croix river between New Brunswick, but speedily abandoned the project on account of the want of water. He then decided on Port Royal, E. side of the bay. During the winter and succeeding spring he was occupied in exploring the coast. He did as far as Cape Cod, Massachusetts, and returned to France. His 3d voyage was taken at the solicitation of De Montes, who once more taken up the idea of founding a colony on the St. Lawrence, near the mouth of the Saguenay. He sailed in 1608, and was received by Pont-Gravé for the next

to France, but the plot was discovered and quashed by the hanging of the ringleader. In 1609 the Hurons, Algonquins, and other Indian tribes, took the war-path against the Iroquois. Champlain, considering the Iroquois dangerous to the colony, joined the Hurons, and descended the Iroquois or Sorel river, until stopped by the falls of Chambly. Here he sent back his boat and crew, keeping only 2 men with himself. With these he accompanied the Hurons in their canoes to the lake, since called Lake Champlain. They had hoped to surprise the Iroquois, but the scouts of that tribe saw them on the lake, so they put ashore, intending to fight, on the next day. Champlain set his allies in order of battle. On the first charge of the Iroquois, 200 in number, he shot their 2 chiefs with his firelock. The enemy fled, and the Hurons returned to Quebec with 50 scalps. In September of the same year he returned to France, leaving the colony under the care of Pierre Chavin. Returning, he left Honfleur April 8, 1610, arrived at Tadousac on the 26th of the same month, landed there, and induced the Montagnez Indians of the place to lend him 60 braves, with whom he once more ascended the river to Lake Champlain to fight the Iroquois. Fortune failed to favor him in this expedition. His allies were defeated, and himself wounded by an arrow, which caused him to return to Quebec, and thence once more to France, where he found Henry IV. dead, and the fortunes of De Monts so broken that he was unable to continue the settlement of his new colony at Montreal. The queen regent, however, having appointed Charles of Bourbon nominal governor of New France, that prince nominated Champlain his lieutenant-governor with extensive powers, which appointment was also continued under the prince of Condé and his relative Montmorency. Champlain returned to America in 1612, again engaged in war with the Iroquois, and extended his discoveries. About this time—but the dates are uncertain—he explored the Ottawa river, to a lake about 65 leagues from its mouth, being in hopes by that route to reach Hudson's bay, just discovered by the mariner whose name it bears, and, with a vague idea of throwing some light on the northwest passage. In 1615 he invited some Jesuit missionaries to the colony. The same year he made an extensive exploration, ascending the Ottawa for some distance, then taking an easterly direction, partly overland, partly by canoe, till he arrived at the eastern shore of Lake Huron; embarked on the lake to a southern point; then going overland to the western extremity of Ontario, he explored that lake and the St. Lawrence as far as the entrance of Lake Champlain, where he made another campaign with the Hurons and wintered with them, returning to Quebec in the spring. Up to this time, Champlain had given more attention to exploring the country, and establishing relations with his neighbors, than to consolidating his power in the

colony. Once more, therefore, he went home, with the intention of importing additional colonists and of getting permission to fortify the settlement. He returned with his family, and the title of governor, in 1620; but it was not till 1624 that his patrons at home enabled him to commence defensive works. Meantime, in 1627, England had declared war against France. Captain Kirk, a Frenchman in the English service, came with an armament of 6 ships, and Quebec, which now contained about 200 souls, being unable to make resistance, capitulated. By the treaty of St. Germain, March 29, 1632, Canada was restored to France. Champlain, being reinstated as governor, strained every nerve to place his colony in a better position than before. Among the means on which he reckoned much was the Christianization of the Indians, especially of his friends the Hurons. His force of missionaries was increased to 15 clergy, with numerous lay brothers. A college was established at Quebec, in which the children of the savages were trained in habits of civilization and in the use of the French language. He did not live to see the result of his efforts, his death having taken place the same year. He was succeeded as governor by De Montagny. Champlain, apart from his merits as a discoverer, was a noteworthy man. His zeal for the propagation of Christianity was great. A saying of his is preserved—that the salvation of one soul is of more importance than the founding of a new empire. While in Canada he devoted himself wholly to the duties of his position, and apparently with a single eye to benefit his patrons. Although traffic with the Indians was very lucrative, he never engaged in it. His views of justice were stern and upright, yet tempered with mercy. He has been accused of credulity in repeating the stories told him by the Indians, but these were omitted in revising his writings. The best edition of his works is that published in 4to., 1640.

CHAMPLAIN CANAL commences at Whitehall, at the S. extremity of Lake Champlain, and runs in a general S. course to the Hudson, which it joins at Fort Edward. Thence it extends along the W. side of the river, passes Saratoga, and joins the Erie canal at Watervliet, opposite Troy. By this canal a water communication was opened between the Hudson and the St. Lawrence, through Lake Champlain. It was completed in 1822, and its total length, including about 17 m. of improved river navigation, is 64 m.

CHAMPMESLÉ, MARIE DESMARES DE, a French actress, born at Rouen in 1644, died at Auteuil, near Paris, in 1698. She was the granddaughter of a president of the parliament of Normandy, but her father being disinherited, she selected the stage as a means of support, made her debut in her native city, and married an actor, Charles Chevillet, sieur de Champmeslé, who had also some talent. Both acquired such fame that they were invited to Paris, where they were successful, especially at the theatre of

Pharaohs. The introduction and the plan of this intended work were read by him, in 1807, to the academy of Grenoble, before he was 17 years old. A few months later he repaired to Paris, where he became acquainted with the most renowned orientalists of the time, Millin, Langles, Sylvestre de Sacy, Chézy, and assiduously attended the lectures at the college of France and the royal school of oriental languages, giving special attention to the Coptic, through which he now hoped to decipher hieroglyphic inscriptions. He consequently prepared a Coptic grammar and dictionary, which he never ceased to revise and enlarge. After perfecting his knowledge of the Arabic, Persian, and Sanscrit, he began in 1808 to perceive a dim light through the arcana of hieroglyphic writing, and by a minute comparison between the Rosetta inscription and a demotic papyrus, he found out the 25 Egyptian letters as set down by Plutarch. To this mode of writing he took such a liking, and acquired such familiarity with it, as to use it even for his private notes. In 1809 he was appointed professor of history in the faculty of Grenoble, and in 1814 appeared the 2 first volumes of his great work *L'Égypte sous les*

and the alphabetic, which part of his great work published in 1824, the government, under the title of *système hiéroglyphique des Égyptiens*, Champollion had, meanwhile, published the first volumes of his *Panthéon Égyptien*, which, however, was not completed. In 1826 he travelled in Italy, and the French government a valuable collection of Egyptian antiquities, which he brought back to Leghorn by the English consul, visited the museums of Turin, and Naples, which he thoroughly examined, giving an account of his recent discoveries in several papers read at the Italian academies, or addressed to distinguished persons in France. The most remarkable of these are the *Première et seconde lettre au roi*, in which he presented several modifications of his system. On his return he found that an Egyptian alphabet had been created at the Louvre by a royal order, he being appointed keeper, and a chair of professor of Egyptian archaeology in the museum. He devoted his attention to these duties, and so arranged the collection that it became a model for all the

is, where he found that he had been member of the academy of inscriptions. In this society he communicated variously his explorations, and especially his *les signes employés par les Égyptiens* and *trois systèmes graphiques à la notation principale des divisions du temps*. He published his *Grammaire Égyptienne*, and his *hiéroglyphique*, while preparing a work for the great descriptive work intended to give the results of his travels in Egypt, and which was to be a complement of ancient Egyptian civilization. The status of this publication, issued in 1831, was the last paper of Champollion; he had a few months before been appointed professor of Egyptian archæology in France, and had opened his lectures when he was obliged to stop them, on account of apoplexy. He tried in vain to continue; he was only able to give the preface to his *Grammaire Égyptienne*, which he considered his best title to the regard of the public. All his manuscripts were purchased by the French government, and published between 1834 to 1848, under the supervision of another.

OLLION FIGEAC, JEAN JACQUES, a naturalist, born in 1778 at Figeac, has been affixed to his patronymic which distinguishes him from his younger brother, a celebrated orientalist. He was at first keeper of the public library and professor of natural history at Grenoble. In 1828 he retired, being appointed professor at the University of Paris, and keeper of the manuscripts (now imperial) library, which office he held until 1848. He is now (1858) librarian at the imperial château of Fontainebleau, and has many valuable manuscripts concerning the history of France, most of them in the possession of the government or the Academy of Sciences. He has aided Silvestre de Sacy and Dacier in several important works, and superintended the unfinished works of his brother, especially the *Grammaire Égyptienne*, the *Dictionnaire hiéroglyphique*, and the *Voyage en Égypte*.

The doctrine of chances is a branch of statistics which calculates the degree of probability of a contingent event, or of the consequences of a result. It is used in the discussion of observations, especially in astronomy and probability; and also in the calculation of life insurance.

CHANCEL, in Gothic architecture, that porch occupied by the clergy, and separated from the nave and aisles by screens of carved stone or oak. The screen which separated the chancel from the nave was called a rood screen, because a rood or large crucifix was placed on it, accompanied with 2 figures representing St. John and the Virgin Mary. The chancel were situated the high altar, or seats for the officiating clergy, and the font, in which the water used for

washing the hands of the celebrant was poured. It was usually surrounded with carved seats or stalls, which were occupied by the clergy not engaged in the services. These were also used when the office was sung in choir, a lectern being placed in the centre of the chancel. The stalls were usually enriched with carvings, and had canopies of carved oak placed over them. The chancel in Gothic buildings occupies the same place with the apse in the ancient basilicas, and was called so from the *cancelli* or rails which were used in the early churches to separate the clergy from the laity.

CHANCELLOR, a law officer known to the polity of several countries. The derivation of the title is uncertain. It has been derived by Coke from the right of cancellation of patents and other royal grants, inherent in this officer, for misrepresentation of facts or on other grounds. But the word chancellor would point to a more ancient derivation. The *cancellarius* of the Roman courts was simply a door-keeper, or usher, to keep back the people who pressed rudely forward to the *cancelli*, or railings. The door-keeper afterward became chief scribe, an official which the Roman church borrowed from the Roman empire, and still retains in the bishop's chancellor. The function of the chancellor is thus described by Blackstone: "When the modern kingdoms of Europe were established upon the ruins of the empire, almost every state preserved its chancellor, with different jurisdictions and dignities, according to the different constitutions. But in all of them he seems to have had the supervision of all charters, letters, and such other public instruments of the crown as were authenticated in the most solemn manner, and therefore, when seals came into use, he had always the custody of the king's great seal; so that the office of chancellor, or lord keeper, whose authority by the statute of Elizabeth is declared to be exactly the same, is with us created by the mere delivery of the king's great seal into his custody, whereby he becomes, without writ or patent, an officer of the greatest weight and power of any now subsisting in the kingdom, and superior in point of precedency to every temporal lord. He is a privy councillor by his office, and prolocutor of the house of lords by prescription. To him belongs the appointment of all justices of the peace throughout the kingdom. Being formerly an ecclesiastic, for none else were then capable of an office so conversant in writing, and presiding over the king's chapel, he became keeper of the king's conscience, visitor in right of the king of all royal hospitals and colleges, and patron of all the king's livings under the value of 20 marks (or £20) per annum. He is the general guardian of all infants, idiots, and lunatics, and has the general superintendence of all charitable uses in the kingdom, and all this over and above the vast and extensive jurisdiction which he exercises in his judicial capacity in the court of chancery." The chancellor of England is a member of the cabinet, and

office; but the increase of government responsibilities has compelled the separation of the duties. In the present generation the office has been in the hands of Mr. Canning, Sir Robert Peel, Lord Althorpe, Mr. Disraeli, Mr. Francis Baring, Mr. Gladstone, Sir Charles Wood, and in 1858 again of Mr. Disraeli.—The CHANCELLOR OF OXFORD or CAMBRIDGE is the chief officer of those collegiate bodies. He is elected and his office is honorary, the duties being discharged by the vice-chancellor.—The CHANCELLOR OF A BISHOP sits in the consistorial court, and is theoretically the bishop's assessor and legal adviser.—In continental Europe there are various political as well as ecclesiastical officials styled chancellors. The chancellor of France was one of the highest officials of the old monarchy. The office was closely analogous to that of England. The chancellor was president of the great council and of the parliaments, drew up ordinances and letters patent, and held the royal seals. It is connected with the illustrious names of Duprat, De l'Hôpital, Birague, Maupeou, Malesherbes, and other distinguished jurists. Louis XV. held the seals himself for a time, and in 1757, the censorship having been associated with the other duties of

he decided in favor of the court, putting his decision merely in the name of the king's arbitrary discretion, which he did not arrogate. The jurisdiction of the court of chancery took its origin from the jurisdiction of ecclesiastical chancellors in cases of mortmain, that is, prohibiting the grant of land to houses. Instead of a grant of land to the parties thus disabled, the writ was introduced of making a person who was under no disability of religious corporations in chancery it was held that the writ was in conscience, and could be granted for the purpose of getting a class of cases that John Walsingham, Richard II., adopted the writ, and ever since been the process of a writ in equity. To understand this innovation, it is necessary to know that all writs for the common law were issued from different courts, though issued by the chancellor, which was not the case, were returnable, not to the court issued, but to the courts which

otherwise as a relief from restraints upon the alienation of property which had long existed. In the reign of Henry IV. and V., the commons attempted unsuccessfully to suppress the writ of subpoena, the object of which was to take away the jurisdiction of the court of chancery; and in the reign of Edward IV. it had become the regular practice of the court to entertain actions commenced by that process. The statute of uses, 27 Henry VIII., by which uses were executed, that is to say, transferred into possession, seemed likely to oust the chancellor of his new jurisdiction, as the courts of common law thereupon took cognizance of a use as being the real ownership of land; but by a narrow construction of the law, by which only one use was recognized by courts of law, the court of chancery was enabled to regain its power. Thus a conveyance to A, for the use of B, in trust for C, was held by common law courts to be a use executed in B, and the trust was a nullity; but in chancery it was held that the 2d was as binding as the 1st, and thus, under the name of trusts, the same class of cases still remained exclusively of equity cognizance. The court having thus acquired the right of calling parties before it by process of subpoena, its jurisdiction was extended to a great variety of other cases, some of which were cognizable by common law courts; but the remark of Blackstone that this was done upon false and fictitious suggestions, and that jurisdiction was obtained of matters that belonged wholly to the common law courts, savors rather of old prejudice than of his usual candor, and is certainly not tenable. Another theory in respect to the peculiar nature of proceedings in chancery is that relief was sought thereby from the rigid rules of the common law. This would seem to be sustained by the case of trusts already mentioned. Another similar class of cases of which chancery took cognizance was that of forfeitures and penalties. At common law, the penalty of a bond was deemed the debt upon non-performance of the condition, and judgment was recovered accordingly; but in chancery the amount really due was considered to be the debt, and on tender thereof with costs of suit at any time before judgment a stay of proceedings was granted. So as to mortgage: at common law the land was forfeited upon non-payment of the bond when due; but in chancery relief was given upon subsequent payment or tender of the real debt. The same doctrine was extended to pledges, and to other personal contracts subject to a penalty or involving a forfeiture. In these cases, it is true that the over-strict rule at common law was the occasion of resorting to chancery for relief, but it is also true that the difference between the courts was not in the construction of what was right in itself, but in the refusal of the common law courts to give a relief according to the right, which they could have done as well as a court of chancery, and which afterward they were compelled to do in respect

to bonds and mortgages, by statute; as for instance, a judgment upon a bond, although nominally for the penalty, could be enforced only for the amount really due; and so mortgaged lands could not be retained after tender of the real debt, and this led to the process of filing a bill in chancery in order to acquire the absolute title. In general, however, it is true that all courts, chancery included, must give the same effect to positive laws, and must be subject to the same rules of interpretation. There are many cases of extreme hardship, but if the law is settled there can be no relief in equity inconsistent with the law; and so in construing agreements and conveyances, courts of law and equity are equally bound to get at the true meaning, and to give to them the same legal effect. The narrowmindedness of judges has indeed made a difference in some cases where there ought to have been none; as when there has been fraud or mistake, which in chancery would be held sufficient to avoid a written instrument or to warrant a modification, in the common law courts it was absurdly held that evidence of such fraud or mistake was inadmissible when the execution of the instrument was once proved. Thus in an action upon a bond, no matter what imposition had been practised, if the signature of the party was proved, the plaintiff must have judgment. So a policy of insurance or other written instrument could not in a trial at law be varied in its effect by the clearest proof of a mistake, but it must first be reformed in a court of equity. Exceptional cases like these have given to the English system, both of common law and equity, an anomalous character, and fully justify the remark of Blackstone that Grotius or Pufendorf, or any other of the great masters of jurisprudence, would have been as little able to discover by their own light the system of a court of equity in England as the system of a court of law. There was a large class of cases to which a jury trial was not adapted, as complicated accounts or multifarious interests in the subject of the suit; yet the former could have been disposed of by references, as has been the practice in the United States, and the other class could have been entertained without difficulty by a modification of the forms of pleading and the framing of issues, as has recently been provided for both in England and America by statute. Upon the whole, there is nothing in the nature of equity as distinguished from common law that would have made it necessary to have a distinct tribunal for its administration, so far as respects the principles involved, if the common law courts had exercised a proper degree of liberality in the discharge of their functions. Writers upon equity usually, however, insist upon 3 distinguishing features of the equity system: 1, the mode of proof, the parties themselves being made witnesses, or at least the plaintiff having the option to compel a discovery by defendant under oath; 2, mode of trial, which formerly was by taking depositions

an early period derived much assistance from the civil law, the most perfect code of law and equity which has ever been compiled, and in doing so did not infringe upon the common law, for that too received large contributions from the same source. The treatise of Bracton, written in the reign of Henry III., a very learned work and of great authority, was very largely made up from the digest of Justinian, and eminent judges have since that time been in the habit of referring to the same source in the settling of new or doubtful questions, and supplying deficiencies of the English law. The great distinction between the common law of England, and that of other countries derived from the civil law, is mainly that in the former equitable relief was excluded, so that another and distinct judicial department became necessary for the administration of equity merely. The prejudice of English lawyers against ecclesiastics, growing out of the introduction of the canon law by the latter, and their attempts to acquire jurisdiction over a large class of cases that did not properly appertain to the ecclesiastical courts, extended also without just cause to the administration of equity according to the civil law, and they uniformly refused all

of the court be adopted in any form. In July, 1850, an act was passed to agree on cases, and to take a summary of the court thereon. Summary jurisdiction was organized in a variety of cases. The writ of habeas corpus was dispensed with in many cases, and the court itself was reduced to a minimum upon objections to forms of process, and referring them to a master. In 1851, another act was passed, by which the offices of the judges were abolished; chambers were created for the vice-chancellors, who were to attend to many of the duties formerly charged by masters. There was also a provision for the reference of questions of accountancy, and other matters, to the Lord St. Leonards. Lord St. Leonards proposed that cases might be sent by the vice-chancellor to the courts of law for their opinion, and that the responding power should be given to the law to get opinions of court. The object was to cut off all embarrassment out of the question of jurisdiction, and to give a final decision in the case of a court without having to come back to the court to take up the case.

ed the combination of equity powers with the common law administration in the same court. They say that the consolidation of the elements of a complete remedy in the same court is obviously desirable, not to say imperatively necessary to the establishment of a consistent and rational system of jurisprudence. The legislation of parliament has, as yet, come far short of this recommendation, but in the acts of 1852 and 1854 great changes have been made in the forms of proceedings in the courts of common law, and some equitable powers have been given to the law courts. In the United States, the federal courts, established in 1789, have administered equity as well as law, without having separate organizations for that purpose. In the state of New York, by the constitution of 1846, the same system has been adopted, and has been carried out by the code of practice with great practical efficiency.

CHANDAH, or CHANDA, a town of Hindostan, capital of a province of the same name, in the territory of Nagpore, distant from the city of Nagpore 85 m., and 430 m. E. from Bombay; lat.  $19^{\circ} 57' N.$ , long.  $79^{\circ} 23' E.$  The town is of considerable extent, surrounded by walls large enough for the heaviest guns. It contains a number of straggling houses, plantations, and a citadel, covering altogether a space about 6 m. in circuit. It was taken by the British, May 20, 1818.

CHANDELEUR ISLANDS lie E. of Chandeleur bay, on the S. E. coast of Louisiana. On the N. or smaller island is a fixed light 55 feet high.

CHANDERNAGORE, a French settlement in Bengal, on the Hoogly, lat.  $22^{\circ} 51' 26'' N.$ , long.  $88^{\circ} 9' 15'' E.$ , 17 m. N. of Calcutta. Pop. 31,235, viz: 30,581 Hindoos, 438 of mixed races, and 216 whites. The town presents a dilapidated appearance. Clive and Watson captured the town from the French in 1757, and dismantled the fortifications; but it was restored to the French by treaty in 1763. It was again occupied by the British on the breaking out of the republican war, and again restored to the French at the general peace in 1815. Some cotton is manufactured in the town, and the chief article of export is opium. The annual revenue of the town and territory is not much above \$30,000.

CHANDLER, ABIEL, a merchant of Boston, born in Concord, N. H., in 1778, died at Walpole, N. H., March 22, 1851, graduated at Harvard college in 1806. He died a widower, without children, and devised \$50,000 to Dartmouth college. He also bequeathed \$1,600 for the establishment of a scientific agricultural school, and the remainder of his estate to the asylum for the insane in New Hampshire.

CHANDLER, RICHARD, an English traveller, born at Elson, in Hampshire, in 1738, died in Feb. 1810. He was educated at Winchester, and at Queen's college, Oxford. An early publication of fragments from minor Greek poets made him known as a man of literary taste,

and his publication of *Marmora Ozoniensia*, the Arundelian marbles, with an accurate transcript of the original, and a good Latin translation, established his reputation as a scholar and an antiquary. In 1763, Chandler was sent with Revett the architect, and Pars the painter, to explore the antiquities of Ionia and Greece. After their return, they published as the result of their labors, in 1769, two magnificent folios of "Ionian Antiquities." Chandler published other works on the same subject. His posthumous life of Bishop Waynesflete, lord high chancellor to Henry VI., was published in 1811. He also undertook to refute the proposition of Bryant, that the Trojan war was a fiction, and that no such city as Troy ever existed. He vindicated the veracity of Homer, and especially the truth of his local descriptions.

CHANDLER, SAMUEL, a learned dissenting English minister, born in 1698, at Hungerford, Berkshire, died May 8, 1766. In an academy at Gloucester, he contracted a friendship with the famous Bishop Butler, and with Archbishop Secker, which continued to the end of their lives. Mr. Chandler, as Presbyterian preacher at Peckham, soon distinguished himself, but unfortunately lost the fortune of his wife in the South sea speculation. He was then a bookseller for some years, without relinquishing his pastoral duties. He also lectured, alternately with Dr. Lardner, at the Old Jewry, where, at last, he was chosen pastor, and where he labored for 40 years. Four volumes of his sermons were published, in accordance with his last desire, by Dr. Amory, in 1768, which were followed in 1777 by a volume of his notes and commentaries on the epistles of St. Paul.

CHANDLER, THOMAS BRADBURY, D.D., an Episcopal clergyman, born at Woodstock, Conn., April 26, 1726, died in 1790. He graduated at Yale college in 1745, in 1747 was appointed catechist and lay reader in St. John's church, Elizabethtown, N. J., and in 1751 went to England for the purpose of receiving episcopal ordination. Upon his return he was made rector of St. John's church, and in 1766 received the degree of D.D. from the university of Oxford. In the political discussions which immediately preceded the war of the revolution, he deemed it to be his duty to sustain the pretensions of the crown; but the current of popular feeling soon set so strongly in the opposite direction that his situation became unpleasant, and even dangerous. Accordingly, in 1775, he went to England, where he was received with every manifestation of the most respectful regard by many of the most eminent personages in the kingdom. On the conclusion of peace in 1783, his congregation earnestly requested him to return and resume his position as their rector. He returned to Elizabethtown in 1785, but in exceedingly ill health. The vestry did not think proper, however, to appoint another rector, and in compliance with their request he consented to retain the station during his life. During the 10 years which he passed in England the government al-

wide, and many of them are well paved. The houses are usually two stories high, and shops are numerous and well furnished. There are two famous temples, now in a dilapidated condition, which are reputed to have attained the good old age of 1,200 years. The town is a busy, animated place, and is the centre of the silk manufacture of the province. It has extensive suburbs, containing large tile and sugar manufactories, while from an eminence near the city as many as 80 populous agricultural villages may be seen scattered over a plain 30 m. long by about 20 m. broad. The port of the city, Amoy, is about 36 m. distant. One of the most remarkable objects to be seen at Chang-choofoo is a bridge across the river. It is built upon 25 piles of stone, about 20 feet high and 30 feet apart. Large beams are laid from pile to pile; these again are crossed by smaller ones, which are covered with earth, and then paved with enormous blocks of granite, some of which are 45 feet long and 2½ feet broad. This singular structure is about 9 feet wide. Half its length on both sides is occupied with shops.

**CHANGARNIER, NICOLAS ANNE THÉODORE**, a French general, born April 26, 1793, at Autun.

troops, known as the army of 10,000 strong. With these forces to control at the same time movements of the Parisian motious aspirations of the president in accomplishing the former fold mission, especially on Jan. 1849, when his vigorous meas attempt at insurrection; but evincing the same boldness and dealings with Louis Napoleon. nier was openly giving the ass that he was ready to protect t illegal measures, the president gaged in carrying out his *coup* garnier found himself unexpected Dec. 2, after which he was banish He has since resided chiefly in

**CHANGEUX, PIERRE JACQUES** savant, born at Orleans, Jan. 26, 1800. His speculations attraction of D'Alembert, Condorcet, a large space in the French Encyclopedia given to an analysis of his most entitled *Traité des extrêmes*. He for his improvement of the be

expensive appendage to the crown. In the 6 months ending June 30, 1858, the imports from England amounted to £234,764.

CHANNING, EDWARD TYRREL, an American scholar, born at Newport, R. I., Dec. 12, 1790, died at Cambridge, Feb. 8, 1856. He entered Harvard college in 1804, but was not graduated in course, as he was involved in the famous rebellion of 1807, in his junior year, on account of which a large number of the most prominent members of the two older classes were obliged to leave college; but received his degree a few years afterward. He studied law with his elder brother, Francis Dana Channing, in Boston, and was admitted to the bar. He gave his attention, however, and his affections, chiefly to literature, and carried forward a careful and critical study of the Greek and Roman classics, with that of the great writers of England. America had not then a literature; but the young men who were his contemporaries and friends have done much toward creating one. The "North American Review," the earliest permanent periodical in America, had its origin in a club of young men, who, in the winter of 1814-'15, projected a bi-monthly magazine. Mr. Willard Phillips, afterward author of the celebrated works on the law of insurance and of patents, was to be its editor. The committee on politics was composed of George Cabot, James Lloyd, John Lowell, Josiah Quincy, and others. The chief managers were to be President Kirkland, Jared Sparks, George Ticknor, Mr. Channing, Richard H. Dana, and John Gallison. At this time, Mr. William Tudor, author of the "Life of James Otis," returned from Europe with a matured plan for a quarterly review; and as the field was not large enough for two such works, the plan of the magazine was merged in that of Mr. Tudor, and the first number of the "North American Review" was issued in May, 1815, as a bi-monthly, the quarterly publication not being adopted until the commencement of the 8th volume. Mr. Tudor edited it for 2 years, and in 1817 it passed under the control of a club composed of the gentlemen named above, and a few others. Mr. Sparks was chief editor for one year, when the duty was undertaken by Mr. Channing, aided by his cousin, Richard H. Dana. Both gentlemen were then under the age of 30. Beside the Boston club, valuable aid was furnished to the "Review" by William C. Bryant, Gulian C. Verplanck, and James Kent, all of them then but little known to the public. In Oct. 1819, Mr. Channing was succeeded in the editorship of the "Review" by Mr. Edward Everett, having been appointed Boylston professor of rhetoric and oratory in Harvard university. This post he held for 32 years, resigning it in 1851. During all this time, the department of rhetoric and oratory, including the charge of all the English compositions of the students, and carrying great influence over their reading and taste, was filled by him with more than satisfaction to the public of reading and thinking men. His labors

were esteemed invaluable, and expressions of gratitude, both public and private, were his constant reward. He established and maintained for the college a high reputation for purity and elegance of style in composition and elocution, and gave direction to the reading of an entire generation of leading men in all departments of intellectual labor. He received the degree of doctor of laws from his university in 1851. Mr. Channing was a constant contributor to the "North American Review," almost to the time of his death. Among these contributions, the following may be noticed as the best specimens of his style of thought and composition: "Lalla Rookh," 1817; "Rob Roy," 1818; "Charles Brockden Brown," 1819; "Southey's Cowper," 1837; "Pryor's Goldsmith," 1837; "Sir Richard Steele," 1838; and "Chesterfield," 1840. In 1856 a volume of his lectures to the senior class at Cambridge was published, being 20 in number, with a memoir by R. H. Dana, jr., of Boston. The topics of the lectures are selected with judgment and taste, and treated with good sense and good feeling, and the style may be pronounced faultless. He contributed the life of his maternal grandfather, William Ellery, to Mr. Sparks's series of American biography. He was highly esteemed for the charm of his conversation, which was choice and pure in style, with an occasional use of a restrained but effective humor. He was a man of pure and just character, thoughtful and scholarly habits, with few and warm friendships; tolerant and liberal views of his fellow beings; a Unitarian of the old school in his theology, and a philanthropic conservative in his politics.

CHANNING, WALTER, M.D., an American physician, brother of the preceding, born at Newport, R. I., April 15, 1786. He entered Harvard college in 1804, but leaving in his junior year on account of the great rebellion of 1807, his degree was conferred upon him afterward out of course. He studied medicine much longer than the usual term, first under Dr. James Jackson in Boston, then under Prof. Barton in Philadelphia. He received the degree of M.D. from the university of Pennsylvania, afterward studied at the university of Edinburgh, and at Guy's and St. Thomas's hospitals in London, and began the practice of medicine in Boston in 1812. The same year he was appointed lecturer, and in 1815 professor, of obstetrics and medical jurisprudence in Harvard university, which office he filled until his resignation in 1854. In 1821, the Massachusetts general hospital was opened in Boston, and his teacher, Dr. James Jackson, was appointed its physician, who named Dr. Channing as his assistant. He labored in the hospital for a term of nearly 20 years, and saw it rise from one patient on Sept. 8, 1821, and 2 on the 20th of that month, to be one of the largest institutions on the continent. Dr. Channing has been a frequent contributor to medical and literary periodicals, beside publishing a volume of

his elders; and he always regarded the tone of his character as due more to silent thought than any companionship. His mind was early occupied by religious and poetic conceptions, by contemplations of power and chivalrous honor, and he sometimes startled his associates by the vehemence with which he would repress any injustice that was attempted. Washington Allston was one of his playmates, and mentions as an instance of the rare uniformity of his moral dignity that even among boys he was always looked up to with respect. The lessons of his mother had developed his religious sensibility, and the doctrinal conversations then in vogue had turned his attention to theology, when at the age of 12 he was sent to New London, Conn., to prepare for college under his uncle, the Rev. Henry Channing. His father soon afterward died, and to the impression of the funeral and the influence of a revival which then swept over New England, with which his uncle as a moderate Calvinist sympathized, he attributed the commencement of his decidedly religious life. A competency was not left to his large family, and thus the necessity of independent energy was added to the elements

ures was furnished by recitations of plays. The interest which his talent social agitations appears in the oration, the "Present Position of the Profession of Arms" delivered at the graduation of the class of 1800, in which he had just selected the profession of arms, 1½ years after leaving college. He was from a private family at Richmond, Va. His youth was passed in agreeable social intercourse, study, chiefly of political and literary subjects. He read numerous works of speculation, seeking the principles of that perfect society which was the object of pursuit by the best minds in England, France, and Germany. He was troubled severely from his anxious and speculative doctrines, and in 1800 he went to Newport to continue his studies. He used to alternate between the city and the sea-shore, on which he spent much of that he had passed his life. In 1801 he removed to Andover, Mass., where he was elected regent in the university. He was how earnestly at this time devoted both to theological and to classical studies, and to the discipline, equally admirably conducted.

ived from Dr. Hopkins. His preaching attracted attention for its fervor and ty, and both the Brattle street and Federal societies in Boston sought to obtain their pastor. Diffident both of his and abilities, he chose to settle over the society in Federal street, and was on June 1, 1808. His congregation increased with his own reputation for eloquence and devotion, till in 1809 the old church was too small to give place to one larger. He refused his mother and sisters to transfer their residence to his parsonage, but by degrees he found it difficult to relax the intensity of his thought and the buoyancy and joyfulness of the soul. Taciturn, or gravely conversing on subjects of highest interest, his solemnity seemed inappropriate to festive scenes, and his expression added to his distaste for them. His whole spiritual energy became concentrated in his labors as pastor, in sermons so exact that he was nearly prostrated at their attending prayer-meetings and Sunday school and in unweariedly ministering to the sick and mourning. By the custom of exchanging with other clergymen, too, he became known throughout New England, and it was said of him and his friend, the younger minister, that they had introduced a new mode of preaching. When the disagreement in the church between the liberal and the conservative Congregationalists, after slumbering for some time, burst forth into the flame of the Unitarian controversy, Dr. Channing was the acknowledged head of the liberal party, and was called to take an active though uncongenial part in its defence. Irreconcilably opposed to the Unitarian scheme and the doctrine of the immanence of God, he was even more at variance with the Unitarianism of Priestley and Belsham; and finding no middle ground in theology, he was led in his enthusiasm for moral and political ideas, and in his high estimate of the capacities of man. He blended in his views which have generally been deemed discordant, and without checking himself by the difficulties, he threw over his complexions the charms of imagination and sentiment and linked it with schemes of moral and social reform. During the period of most intense debate his pure and glowing character shone on the constant admiration of his opponents. In 1814 he married, and soon after made some acquaintance with the master of Germany through the refined thought of Madame de Staël. From Kant's doctrine of reason he derived deeper reverence for the powers of man; by Schelling's intimations of the Divine Life everywhere manifest, he was made more devoutly conscious of the universal agency of God; and he was highly delighted with the heroic stoicism of Spinoza and his assertion of the grandeur of the will. But for his greatest pleasure and discipline he was now indebted to Wordsworth, whom he esteemed next to Shakespeare,

and whose "Excursion" came to him like a revelation. With Wordsworth's mingled piety and heroism, humanity and earnest aspiration, with his all-vivifying imagination, recognizing greatness under lowliest disguises, and spreading sweet sanctions around every charity of social life, and with his longings to see reverence, loyalty, courtesy, and contentment established on the earth, he most closely sympathized. From this time he began to engage more actively in political and philanthropic movements. Outraged by the issue of the French revolution and the stern sway of Napoleon, he delivered, June 15, 1814, a discourse on the overthrow of the emperor and the "goodness of God in delivering the Christian world from military despotism." He early gave his sympathy and support to Noah Worcester, the father of the peace movement in this country, and in 1816 preached a discourse on war before the convention of the Congregational ministers of Massachusetts, which was printed and widely circulated, and prepared the way for the formation of peace societies in several of the states. The cause of temperance, of reform in penitentiary discipline and punishments, of missions, and of Bible distribution, all received his encouragement. His church was always thronged when he preached, and by various public discourses, among which were sermons occasioned by political crises, his Baltimore sermon on the Unitarian controversy, delivered in 1819, and his Duddleian lecture on the "Evidences of Christianity," delivered at Cambridge in 1821, his celebrity was extended throughout the country. In 1822 he made a European tour, saw Wordsworth and Coleridge in England, the latter of whom wrote of him: "He has the love of wisdom and the wisdom of love," and visited France, Switzerland, and Italy. On his return he resumed his pastoral labors with more than his former energy, till in 1824 he received as colleague the Rev. Ezra Stiles Gannett; and from this time his efforts were more in the general field of literature and reform. His remarks on the character and writings of Milton, his two articles on the life and character of Bonaparte, and an article on Fénelon, published in the "Christian Examiner" between 1826 and 1829, attained a very wide celebrity, and brought him into correspondence with several of the most eminent literary persons in England and America. His writings are most characteristic and effective when treating questions of Christian philanthropy and social reform. In behalf of peace, temperance, education, and freedom, he repeatedly came before the public, and he examined with sympathizing respect and anxious scrutiny every movement which promised more happy social relations. Without accepting absolutely the doctrine of non-resistance, he remonstrated against war, reviewing its crimes and miseries, in 1835, when there was danger of a rupture with France, and in 1839, when there was a prospect of conflict with Great Britain. The wide scope which he gave to education is seen in some of the most

his personal character are needed to adequately estimate him. In unvarying moral dignity, and in the wide scope and constant glow of his moral feelings, he has perhaps never been surpassed. His words as well as his opinions were usually chosen from among those which express the sunny, hopeful, and possible view of things, and so predominate in his style that it is transparent with moral beauty. He should be judged as he is remembered, not merely as a thinker, but as a preacher and a Christian. He was buried at Mount Auburn, where a monument, designed by his friend Washington Allston, was dedicated to his memory.—The most complete edition of his works was published in Boston, in 1848, in 6 vols. 12mo. In England appeared in 1849 a selection of his works by Mountford, under the title, "Beauties of Channing." Many of his essays have been translated into German at various times, and a more complete selection of his works was translated by Sydow and Schulze, and appeared in Berlin, 1850-'51. His biographer was his nephew, the Rev. William Henry Channing, whose work was published in 1848, simultaneously in Boston and London, under the title of "Memoirs of William Ellery Channing, with Extracts from his Correspondence and

1840, 2 vols.), in *English Literature*; "Memoirs of William Ellery Channing," 3 vols. (Boston and Writings of James H. F. "Memoirs of Margaret Fuller 1852), in connection with R. W. F. Clarke; sermons, reviews, &c. He is at present pastor of the H. (Unitarian), Liverpool, Eng., the pastoral care of the Rev. J. Mr. Channing has labored no forms, and his views of the Christian spring from central principles in the Christian faith. He has a solicity of sympathy to the church, and he advocates his much zeal and eloquence. His discourses are often extemporarily delivered in a style highly imaginative. The vision of a universal fraternized form of human society of Jesus Christ on earth creates and inspiration of the gospel; man, fills his horizon, and as Mr. Channing, during a considerable part of his career, has been an earnest and constant

tions that the Christians assembled at break of day to chant their hymns. The chant grew with the progress of Christianity. Pope Sylvester, in 339, founded a school for its culture; and St. Ambrose, bishop of Milan from 374 to 397, arranged from the old Greek music a new description of chant, the Ambrosian, which remained in use until superseded by the chant arranged by Pope Gregory, 590 to 604, hence called the Gregorian or Roman chant, and which, somewhat modified, is in use at the present day. Chants are, properly, of 3 kinds: the monody, sung by 1 voice; the antiphony, alternately by 2; and the choral, by all voices.

CHANTAL, JEANNE FRANÇOISE FREMIOT DE, a saint of the Roman Catholic church, born at Dijon in 1572, died at Moulins in 1641. Her husband was killed while hunting, and although she was only 28 years of age, she took a vow never to marry again. From this time her sole occupation and recreation was the education of her children and the care of the sick and the poor. She became acquainted with St. Francis de Sales in 1604, and from that time placed herself entirely under his direction. He communicated to her his project for the establishment of the order of the Visitation, and she so far entered into his views that in the year 1610 she laid the first foundation of that order at Annecy. She established her children in life, and then devoted the remainder of her days to the order. At the time of her death she had founded 37 houses of the Visitation. In the year 1700 they numbered 150, and about 6,600 members. Her beatification took place in 1751. She was canonized by Clement XII. in 1767. Her life and letters were published in Paris, 1779.

CHANTIBUN, or CHAN-TI-BUN, an inland town of Siam, capital of a province of the same name, situated on a river at the foot of a chain of mountains, 18 m. E. from the gulf of Siam, in lat. 12° 45' N. and long. 102° 18' E. It produces pepper, rice, gamboge, cardamoms, rosewood, dye-woods, ivory, and benzoin. Foreign commerce being prohibited, the entire produce of the country is removed annually to Bangkok, 150 m. S. E. Near the town are mines of precious stones. Pop. estimated at 30,000, a large proportion of whom are Chinese.

CHANTILLY, a charming locality in the vicinity of Paris, department of Oise, pop. 2,454, famed for its laces, porcelain and other manufactures, and annual horse races. Its historical celebrity is due to the castle which since 1632 has been the seat of the Condé family. It was given to them by Louis XIV., having previously belonged to the Montmorency family, and was bequeathed to the duke of Aumale in 1830. The great Condé gave in this castle splendid entertainments to the king, the poets, and the eminent persons of France. That given to the king in 1671 was rendered remarkable by the suicide of Vatel, the head steward, who ran himself through with a sword, because the fish did not arrive in time for dinner. The grand château was destroyed by the mob at the first revolution;

there now remain only the "petit château," the "château d'Enghien," and superb stables, capable of lodging 240 horses, but untenanted. In the parish church of Chantilly, the remains of Coligni were interred after the massacre of St. Bartholomew's, after his head had been cut off and sent to Catharine de' Medici. An interesting description of the beautiful forest, and the various attractions of Chantilly, occurs in Lord Mahon's "Life of Condé." The pictures of Condé's battles were in the petit château down to 1852, but have since been removed to Twickenham.

CHANTREY, SIR FRANCIS, an English sculptor, born in Derbyshire, April 7, 1782, died Nov. 25, 1841. Showing a taste for sculpture, he was placed with a carver in Sheffield; but finding his genius adapted to a higher walk in art, he began to model in clay, and established himself successively in Dublin, Edinburgh, and London. He made the latter place his home, and by the assistance of Nollekens and his own talents soon acquired considerable reputation. He was elected a royal academician in 1818, and in 1837 was knighted. As a maker of busts and a monumental sculptor, Chantrey held a respectable position. He executed an immense number of works, among the best of which are his bronze statues of William Pitt, Canning, and Bishop Heber, and the bust of Walter Scott. His statue in marble of Washington is in the state house at Boston. He amassed considerable property, the greater part of which he directed to be invested for the encouragement of art.

CHANTRY, an ecclesiastical endowment to provide for the celebration of masses for the prosperity of the living or repose of the dead. Previous to the reformation, chantries were very numerous, almost every family of importance having founded one or more. Wealthy founders would endow a church or monastery, in which religious services should be celebrated continually. For less wealthy founders, an altar in the church of the locality was made to suffice. Sometimes small chapels, called chantry chapels, were appended to the main edifice. The residences of priests engaged in the services were known as chantry houses, chantries, or colleges. Chantries were dissolved in England by King Edward VI., and all endowments for the purpose confiscated to the king.

CHAOS (Gr. *chaos*, from *chaō*, to be open or void), in classical mythology, either the empty and infinite space which existed before all things, or the *mélange* of all the elements, the confused mass out of which the ordered creation was formed. By the poets it was personified, and made the most ancient of the gods, the father of Erebus and Night. The principle of the fecundity of chaos assumed several modifications in the Greek systems of philosophy. Something similar to the Greek conception of chaos is found in the Phœnician, Chaldean, and Indian cosmogonies; and Ovid's description of the genesis of the universe out of chaos has so many features in common with the Mosais

the use of the term has been extended so as technically to include all religious edifices not of the established faith. Thus in continental Europe Anglican places of worship are chapels, while in England Roman Catholic and dissenting places of worship are styled chapels. There are also in the established church itself in England chapels of ease to parish churches, built for the accommodation of worshippers in populous or extensive parishes. In Roman Catholic churches portions of the main building are often set aside and dedicated to particular saints. These are called chapels, in which a service is performed in honor of the saint.

CHAPEL HILL, a post village of Orange co., N. C. It occupies a healthy and agreeable site on the New Hope river, an affluent of the Cape Fear, and is the seat of the university of North Carolina, a flourishing institution founded in 1789. See NORTH CAROLINA, UNIVERSITY OF.

CHAPELAIN, JEAN, one of the earliest members of the French academy, born in Paris Dec. 4, 1595, died Feb. 22, 1674. Having gained a high literary reputation, more by ingratiating himself with Richelieu and other influential persons than by his intrinsic merits, he

1851. He was a prominent missionary, Bible, and temperance worker. He was the first recording secretary of the American board of commissioners for foreign missions, and held that office for

CHAPIN, EDWIN HERBELL, an American clergyman, born in Union Vt. Dec. 29, 1817. He received his formal education in a seminary at Union, Vt. He commenced preaching in 1837, and was first settled over a church of Unitarians and Universalists in Va. Thence he removed to Union, N. Y., in 1840; then to Boston in 1846; and to New York in 1848, to take charge of the 4th Universalist church in that city, where he still remains pastor. He received the degree of D.D. in 1856, from Harvard university, which had previously conferred on him the degree of A.M. Dr. C. is widely connected with the Universalist cause, but his sympathies far outstep the boundaries of a sect. His religious views are originally affected powerfully by his published writings, as well as by his personal labors in the cause of the Universalist faith; and he has

a voice of remarkable richness and volume. Men are so liberally endowed with the capacity for vigorous and connected extempore address.

It is his custom, however, to produce one carefully written discourse every week, which is taken from manuscript, and, in the morning service of his church, to preach with very little verbal preparation. The church over which Chapin presides is situated in Broadway, and the morning and particularly the evening services are so numerous attended, that it is recently difficult for a stranger to find a seat. The congregation comprises many of the young active men of New York, and persons of the most conflicting theological opinions. In addition to the labors demanded by so large a parish, Chapin finds time for a great deal of service as speaker before lyceums and literary associations; while as a temperance advocate, and a platform orator in behalf of public movements in which moral interests are prominent, he exercises a continually increasing influence. His speech before the peace convention at Frankfort-on-the-Main, in 1850, is perhaps the most celebrated of all his successes in popular oratory. Dr. Chapin's published works consist of several volumes of sermons and religious lectures, and a few occasional discourses. One of those volumes, "The Crown of Thorns," has obtained a very wide circulation, and its devout and cheerful spirit has made it welcome beyond the circle of those who are in sympathy with the author's theological creed.

CHAPIN, STEPHEN, D.D., an American clergyman, born in Milford, Mass., Nov. 4, 1778, died in Washington, D. C., Oct. 1, 1845. The son of pious parents, his thoughts were turned at an early age to the subject of personal religion, and while yet a youth he became a member of the Congregational church in his native town. He soon after began to prepare himself for college, with a view to the profession of the Christian ministry, and graduated at Harvard university in 1804. After leaving college he went to study theology with the celebrated Dr. Emmons, of Franklin. After a brief period of study with that able theologian, he was called to the pastoral care of the Congregational church in Hillsborough, N. H., where he was ordained in 1805. Disagreeing with his church in reference to what was known as the "Half-way Covenant," not only refusing to baptize the children of non-professors himself, but declining to exchange with other ministers with a view to their performance of the duty in his parish, his pastoral relation in Hillsborough was severed early in 1809. In November of the same year he accepted the pastoral charge of the Congregational church in Mount Vernon, N. H. The controversy into which he had been drawn with his people in Hillsborough led him to a more particular examination of the whole subject of church membership and church ordinances, the result of which was his adoption of the general views held by the Baptist denomination. He accordingly re-

linquished his pastoral charge in Mount Vernon early in the autumn of 1818, and in November of that year was baptized by the Rev. Dr. Baldwin, pastor of the 2d Baptist church in Boston. In 1819 he became pastor of the Baptist church in North Yarmouth, Me., where he remained but a year or two, having been called, in 1822, to the chair of theology in the newly established college at Waterville, Me. He entered on the discharge of the duties of his professorship with characteristic industry and zeal, and enjoyed the entire confidence of his patrons until he was called to fill a more responsible post. An effort having been made to resuscitate Columbian college at Washington, and obtain an endowment which should secure it against the embarrassments under which it had for some time labored, Dr. Chapin was selected as a suitable person to preside over its affairs. He was elected president of that institution in 1828, and continued to preside over it with marked ability until 1841, when he resigned a post which he had filled with honor to himself and with advantage to the college. He continued to reside in Washington until the time of his death. Dr. Chapin was a scholar of large attainments, amiable in temper, yet earnest and energetic; prudent, but always true to his convictions and firm in maintaining them.

CHAPIN, WILLIAM, an instructor of the blind, born in Philadelphia in 1802, occupied the early part of his life in literary pursuits and in the publishing business. In May, 1840, he assumed the function of principal of the Ohio institution for the blind, and did much to improve the system of education there, the number of pupils having increased under his administration from 18 to 72. Having investigated kindred institutions in various parts of the United States, he visited Europe in 1845, and embodied the results of his investigations in a report to the legislature of Ohio, "On the Benevolent Institutions of Great Britain and France." Resigning his post in Ohio in 1846, owing to changes made by the legislature, he was elected in Sept. 1849, principal of the Pennsylvania institution for the blind, which post he still holds.

CHAPLAIN, a clergyman appointed to say prayers and to perform divine service, and attached to some body of persons or the household of an individual for that purpose. In the United States chaplains are appointed to legislative bodies, hospitals, prisons, regiments, and vessels of war. In Europe chaplains are attached to courts, and also sometimes to the families of the nobility. The origin of the term is generally associated with chapel. It belongs both to the Catholic and Protestant churches. In England, chaplains are exempted, in respect of their appointment, from the operation of the laws against plurality of benefices.

CHAPLET. See BEADS.

CHAPLIN, JEREMIAH, D.D., an American minister of the Baptist denomination, born in Rowley, Mass., Jan. 2, 1776, died at Hamilton,

N. Y., May, 1841. His heart was imbued with religious feeling at a very early age. He graduated at the college of Rhode Island, afterward Brown university, in 1799. After graduating he was immediately elected tutor, and remained in that capacity for about 3 years. In 1802, he became the pastor of the Baptist church in Danvers, Mass., which relation he sustained until 1818, when he was selected to take charge of the literary and theological seminary then about to be commenced in Waterville, Me. This institution had its origin in a desire to promote theological education among the Baptists of New England. More comprehensive views soon prevailed, and the seminary was changed into a college in 1820. In 1821 Dr. Chaplin was elected its first president. He administered the government of the new college with great discretion and success for about 12 years. After retiring from the presidency of the college, he became pastor of the Baptist church in Rowley, his native town. Subsequently he became the pastor of the Baptist church in Willington, Conn., where he remained till near the close of his life. Few men of the past generation were more entitled to the respect and veneration of mankind than Dr. Chaplin. His own denomination, especially, owe him a debt of gratitude for his powerful and indefatigable efforts to promote the education of its ministry.

CHAPMAN, GEORGE, an English poet, the earliest English translator of Homer, born probably at Hitching Hill, in Hertfordshire, in 1557, died in London, May 12, 1634. After studying 2 years in Trinity college, Oxford, where he was distinguished for his knowledge of the classics, he went in 1576 to London, where he enjoyed the friendship of Spenser, Shakespeare, Marlowe, and Jonson, and the patronage of King James and Prince Henry. He published a translation of 7 books of the Iliad in 1598; of 12 books in 1600; and of the whole poem in 1608. It is in the lofty 14-syllable English verse, and of a vigorous and imaginative character more accordant with the spirit than the letter of the original. It has retained its popularity both with poets and scholars, though less polished and less accurate than the version of Pope. Pope said that it was "something like what one might imagine Homer himself would have written before he arrived at years of discretion;" Waller could not read it without transport; and Keats has expressed his admiration of it in one of the most beautiful of his sonnets. Chapman afterward translated the Odyssey, the Homeric hymns, and portions of Ovid, Terence, Musæus, and Petrarch. He was also a voluminous writer of plays, only passages of which are now esteemed. He was associated with Jonson, Marston, and others, in writing the comedy of "Eastward, Ho!" which contained severe satirical reflections upon Scotchmen, and was therefore so ungrateful to King James, that he caused the authors to be for a short time imprisoned. An imitation of Terence entitled "All Fools," was highly applauded by

his contemporaries; and portions of the tragedy of "Bussy D'Ambois" were highly esteemed by Charles Lamb. A handsome edition of his translations from Homer was published in London, in 5 vols., in 1858.

CHAPMAN, JOHN GADSBY, An artist, born in Alexandria, Va. In his youth, his taste for design, he was encouraged by the liberality of a friend to travel to study and practise his art there for several years. After his return to the U. S. he removed to the city of New York, where, by his rare union of mechanical skill and artistic taste, he rapidly obtained great reputation. He has executed many commissions for the illustration of works of literature, among which are Harper's Bible, Schuchert's "Tales," and Whittier's "Song of the Laborer." He also painted the "Baptism of Christ," one of the panels in the rotunda of the U. S. Capitol. In 1848 he again visited Rome, and has since resided.

CHAPONE, MRS. (HESTER MCLERO), an English authoress, born in Northamptonshire in 1727, died at Hadley, Dec. 21, 1801. At the age of 9 years she is said to have written a romance, and she early studied several languages and treatises on morals and philosophy. Her first publications were the story of "Fidelia" in the "Adventurer," and some verses prefixed to her friend Miss Carter's translation of Epictetus. In 1760 she married Mr. Chapone, who died within less than a year. In 1770 she accompanied Mrs. Montague to Scotland, at whose request she soon after published her "Letters on the Improvement of the Mind." In a volume of "Miscellanies," which subsequently appeared, are several letters addressed by her to Richardson, controverting some of the maxims put forward by him in his "Clarissa Harlowe."

CHAPOO, a maritime town in the province of Che-kiang, China, situated on a promontory on the N. side of the estuary of the Tchen-tang (or Tsien-tang), communicating by canal with Hang-chow-foo, of which place it is the port. Its suburbs, which are very extensive, and the seat of most of the trade, extend along the water's edge. About half a mile in their rear is the walled town, 5 m. in circumference, enclosed within which is the Tartar town. Its harbor is very shallow, and the tides are rapid, but there is deep water in the roadstead, and all the trade of China with Japan is carried on from this port. The soil of the neighboring country is extremely fertile and well watered, and the surface is interspersed with numerous villages, pagodas, temples, &c. The adjacent heights, fortified during the late war, were captured by the British, after an obstinate resistance, May 18, 1842.

CHAPPE, CLAUDE, a French engineer and mechanic, born at Brulon in 1763, died Jan. 23, 1805. Having invented an ingenious system of signals to communicate at a distance with his friends, he presented it to the French legislative assembly in 1792. It was successfully

ried between Paris and Lille, on a length of 48 leagues, and was adopted by the government.

Chappe established several lines in France, and the one running N. was first put in motion to announce the recapture of the town of Condé from the Prussians. The inventor was at once rewarded by the convention, which, by a decree, appointed him *ingénieur télégraphe*. The lines were extended all over France, and the system was also adopted, with some alterations, through Germany and England. The attacks to which he was subjected, by persons jealous of his invention, preyed so much upon his mind that he committed suicide.

CHAPPE D'AUTEROCHE, JEAN, a French astronomer, born at Mauriac, Auvergne, in 1722, died Aug. 1, 1769, in California. He was a priest, but giving his whole attention to astronomy, he became one of the assistants of Cassini in delineating the general map of France, and edited the astronomical tables of Dr. Halley. In 1760 he was designated by the academy to make an observation of the transit of Venus over the sun's disk, which Halley announced would happen June 6, 1761. He consequently set out for Tobolsk, in Siberia, which was pointed out as the most favorable point of observation. His mission was successfully accomplished; and returning to France at the end of 2 years, he published in 1768 his *Voyage en Sibérie*. The following year he sailed for California to observe another transit of Venus, which was to take place June 3. He was equally successful on this occasion, but died soon afterward. The results of his last expedition were published by C. F. Cassini, under the title of *Voyage de la Californie*.

CHAPTAL, JEAN ANTOINE CLAUDE, count de Chanteloup, a French chemist and statesman, born at Nogaret, Lozère, June 4, 1756, died in Paris, July 30, 1832. During his medical studies and practice he devoted much research to the science of chemistry, in which he soon became eminent, and was appointed professor at Montpellier, where he taught successfully the doctrines of Black, Lavoisier, and Cavendish. His uncle, a wealthy physician, left him a fortune, with which he established chemical works near Montpellier, being the first attempted of the kind, and by which he was soon enabled to produce various chemicals hitherto imported, such as the mineral acids, alum, soda, and salts of lead. The authorities of Languedoc heaped honors on him; the Spanish government offered him a pension of 56,000 francs to go to Spain; and according to his biographer, Washington wrote 3 times to Chaptal, inviting him to America. After the outbreak of the French revolution he published a political pamphlet, entitled "Dialogue between a Montagnard and a Girondist," and was arrested, but through the intercession of friends was liberated. The committee of public safety placed him in charge of the powder mills of Grenelle, which produced, under his management, 3,500 lbs. of gunpowder daily. Once

more returning to Montpellier, he was elected member of the institute, and devoted himself to science, till Bonaparte summoned him to the council of state, where he had the supervision of national education. When Lucien Bonaparte resigned the portfolio of the interior, Chaptal took his place as minister, and for 4 years performed the duties of the department with much administrative ability. He founded the conservatory, school of arts, and society for encouragement of industry, introduced the modern French system of weights and measures, established a model farm and a system of distribution of agricultural seeds, reorganized the prisons and hospitals, extended the network of highways over the face of the country, and organized the carrying out of the plans of extension of the Louvre and rues de Rivoli and Castiglione, that have since been completed by Napoleon III. In the midst of his usefulness a misunderstanding arose between him and Napoleon; some accounts say, because Chaptal refused to report in favor of beet root over cane sugar, while others assert that it was on account of an actress, named Mlle. Bourgoïn, to whom both emperor and minister paid their devotions. A reconciliation afterward took place, and the ex-minister was made count, senator, and grand officer of the legion of honor. On Napoleon's return from Elba, the count was appointed director-general of commerce and manufactures. Louis XVIII. struck him from the list of peers, but left him on the roll of the academy. He died at a ripe age, a useful, but not a brilliant man. His fortune was much reduced by the indiscretions of his son. His works are all on chemical subjects, and may yet be consulted with advantage, especially his "Treatise on Chemistry applied to the Arts."

CHAPTER, the community of canons or prebendaries attached to a cathedral or collegiate church, and presided over by a dean. (See CANON.) They govern the diocese during the vacancy of the see, in some countries have the right of choosing the bishop, and act as his advisers. In England, the appointing privilege was assumed by Henry VIII. as a royal prerogative; it is also exercised by the crown in Prussia and other Protestant countries. Some of the Roman Catholic cathedrals in England have their chapters, but there are none in the United States. They were suppressed in France by the civil constitution of the clergy, but restored by the concordat of 1802. The title of chapter is applied not only to the canons in their collective capacity, but also to their meetings, and to the place in which the latter are held. It is given to the assembly of members of a religious order, to the convocations of the military orders of the middle ages, and even to the meetings of certain corporations of mechanics and tradesmen. It was first used about the 8th century, and is supposed to have originated in the fact that at such sessions it was customary to read some or all of the chapters containing the rules of the community.

position when Scott stormed and took Molino del Rey. His next step was anxiously looked for by the enemy. He had already advanced a force near to the city walls, and seemed to be making preparations for attack. Another portion of his force menaced Chapultepec in a similar manner. Blows had fallen so rapidly in places where they were least looked for, that Santa Anna was at a loss to divine whether the city or the castle were the real object of attack. Bravo sent word to Santa Anna that Scott would certainly first assault the castle, being too skilful a general to leave such a work in his rear. It was not till the Americans had all preparations ready for the assault—indeed, not until the castle was taken—that the Mexicans discovered that the demonstration against the city had been only a feint to prevent them from reënforcing Chapultepec. Scott from the first had determined to carry this work. His loss in killed and wounded at Molino indicated a different mode of attack from that by which the victory of the 8th was won. Accordingly, on the evening of Sept. 11, he ordered Colonels Lee and Huger to erect 4 batteries on a ridge facing the fortress. These works were placed

the stormers planted their ladders. Many brave fellows were hurled to their length a lodgment was effected. In the meantime was doing the same having beside captured 2 batteries. In a strong body of the enemy with the rifles and the New York, Indiana, and Pennsylvania volunteers in time to share in the honor. After a stout resistance the enemy were driven from their defences, and the Americans as well as the standards of the United States participated in the capture, were taken to the ramparts. The cessation of firing and the cheers of the victorious Americans were distinctly heard in the city. Santa Anna then fled to Chapultepec. Crowds of fugitives fallowed him. He told the same tale, and showed the same weakness. As far as Mexico was concerned, the war was over. Victory was gained with small loss to the Americans. The Mexicans were not ascertained, but must have been driven back. The stormers pressed forward, and soon the city was won by the occupation of the castle. CHARA, an aquatic plant in

, and always turn in a contrary direction the rings on the seed-vessel.

**CHARADE**, a species of enigma, which con-

dividing a word into syllables, each of which is a complete word, and vaguely describing each of the parts and the word. For a charade to have literary members must have some relation to a story, and unite in an epigrammatic point, invented in the latter part of the last century, and has been most cultivated in Germany. The *Mercur de France*, prior to the revolution, contained stores of charades, and logogrimphs.—**ACTING CHARADES** are in obscurely indicating the signification of words by pantomimes and dialogues.

**CHARBAR**, or **CHOURAR BAY**, one of the best harbours on the coast of Beloochistan, in the Indian ocean. Ras Charbar, the E. point of the bay, is in lat. 25° 16' N., long. 60° 35' E. On the side of its entrance is the town of Charbar, 1,500, surrounded by a rampart of mud and garrisoned by the imam of Muscat. To the S. of this are the ruins of the Portuguese fort of Teez, probably the Tiz of Edrisi. To the N. is the Troesa of Nearchus.

**CHARCOAL**, the solid residue obtained by the charring of organic bodies to destructive distillation. Animal charcoal has been described as **BONE BLACK**. Wood charcoal is an impure form of carbon, containing the ashes or combustible portions of the wood from which it is prepared, and also some of its volatile ingredients. The principal object of its charring is the greater calorific effect it has than wood. Its properties vary greatly according to the nature of the substance charred and for its preparation and the manner in which this is conducted. Well charred wood, as birch, beech, or maple, retains the form of the wood, is of a glossy black, burns without flame or smoke, rings with a sharp crack, and bears a considerable blow without breaking. It is still, however, brittle, and splits square across the grain. It may be charred without soiling the fingers. Its weight when powdered is nearly double that of water, and masses it was found by Hassenfratz to be nearly equal with its porosity, and this seemed dependent on that of the wood. Birch, 0.203; oak, 0.155; alder, 0.184; beech, 0.183. Other authorities make these figures still higher. The composition of charcoal prepared from a variety of woods has been determined by M. Violette, who was employed by the French government to conduct a series of experiments in this branch of manufacture.

The same method of expelling the volatile matters was adopted in each case, viz., the action of highly heated steam, so that the differences of composition are evidently to be referred to the difference in the principles of the woods, and to the greater or less difficulty with which they are decomposed. The following table presents the proportions of the elements in 100 parts of charcoal:

VOL. IV.—46

Species of charcoal.	Carbon.	Hydrogen.	Oxygen, nitrogen, and loss.	Ash.
Furze .....	75.639	4.108	17.975	1.268
Ironwood .....	72.544	4.837	19.518	0.299
Cork .....	71.868	5.588	19.110	..
Juniper .....	71.488	5.078	23.374	0.170
Wild pine tree .....	71.808	5.948	22.194	0.509

Pear tree .....	67.127	5.810	28.944	0.523
Hemp stalks .....	67.127	4.976	21.501	1.398
Wheat straw .....	67.127	4.985	24.789	0.739
Leaves, poplar .....	68.514	4.813	41.239	1.398

The proportion of ash is smaller than the known composition of the woods would lead us to expect. This differs very much in different woods, in some amounting to 5 or even 10 per cent. Winkler obtained in charcoals the following proportions of ash in 100 parts:

Lime .....	2.85	Pine .....	1.85
Maple .....	2.37	Poplar .....	1.80
Ash .....	2.37	Beech .....	1.25
Elm .....	2.17	Scotch fir .....	1.11
Willow .....	1.50	Birch .....	0.80
Fir .....	1.44	Oak .....	0.78

Charcoal absorbs water from the air, and in a few days gains from 10 to 20 per cent. in weight. Afterward it loses and gains within these limits as the air is dry or damp. The temperature at which the carbonization has been effected appears to have a remarkable influence upon the amount of water the coal can absorb; the lower this temperature the greater the absorption. Some of Violette's results, obtained by exposing charcoal of black alder, prepared at increasing temperatures, to air saturated with moisture, are given in the following table:

Temp. of carbonization, deg. Fahr.	Quantity of water absorbed by 100 gm. of charcoal.
500 .....	20.000
520 .....	18.180
540 .....	11.000
560 .....	9.700
580 .....	8.800
600 .....	8.000
620 .....	7.600
640 .....	6.800
660 .....	6.200
680 .....	5.800
700 .....	5.200
720 .....	4.800
740 .....	4.700
760 .....	4.600
780 .....	4.444
800 .....	4.333
820 .....	4.286
840 .....	4.231

The temperature of carbonization also influences that at which charcoal takes fire. Wood charred at 500° F. takes fire at 644°; and when charred at temperatures ranging from 554° to 682° it is found to ignite at 690° to 696°, and at increased temperatures proportionally higher.

curate to calculate this by measure; for when in large quantities it would be by mere accident if 2 measurements gave the same result.—Charcoal possesses an extraordinary capacity of absorbing gases, some of them in very large quantity. Of ammoniacal gas it was found by Saussure to take up 90 times its bulk; of hydrochloric acid gas, 85 times; of carbonic acid, 35 times; of nitrogen,  $7\frac{1}{2}$ ; and of hydrogen,  $1\frac{1}{2}$ . When filled with one gas and exposed to another, a portion of the former is evolved and its place supplied with a portion of the latter. This absorption and condensation of gas within its pores is accompanied with an increase of temperature, which is sometimes sufficient to cause spontaneous combustion. This is particularly the case with freshly charred coal from the pits, and it is probable that many of the instances, so frequent, of the heaps taking fire after the charcoal is drawn out, or after being placed in the wagons, are owing to this property. Coal which is very black, without having been charred too much, and fine, is most likely thus to take fire. Charcoal also absorbs colors, and abstracts the smell and taste of organic substances in solution; hence its use for

for pine and well-seasoned  
localities where the ordinary  
ering are scarce. It is called ch  
Around 8 sides of an area of

cord wood and the lining, which is to prevent it from taking fire. The lining at the bottom of the enclosure is to be similarly prepared.

The wood is laid horizontally in 2 rows across the enclosure, beginning at the bottom, and piling all along to within 8 inches of the top of the lining. It is then covered as in the preceding methods; fire is set to the lower end, the top is partially covered, and vent holes are made near the upper end; other holes may be made, as the process goes on, through the covering.

In 24 hours, if the operation is well conducted, charcoal may be drawn from the bottom, and its removal may be continued successively to the extreme end. In the ordinary method, the wood, which, to produce the greatest quality or largest quantity of charcoal, the shortest time, should be seasoned, is piled in stacks, sometimes in horizontal rows, but more frequently in ranges of logs, the ends of which are placed on end, and in tiers one upon another around a central aperture, which is opened to the top of the heap. This aperture is for a temporary chimney, and also for forcing the fire for igniting the heap. For another purpose, a horizontal channel is sometimes left in the base, extending to the centre.

Sticks of wood are built up in a conical or hemispherical form, and are closely packed with small wood to fill the apertures. They are of convenient size, from 10 to 30 or 40 feet in diameter, and in height not exceeding the diameter.

The outer surface is then well filled in with chips and sticks, covered with small branches, twigs, leaves, or moss, upon which sods are laid, or covered with the fine charcoal waste of previous seasonings, called braise. This is moistened with water, and mixed with as much earth as may be required.

When wet, it makes the best of all coverings. Around the bottom of the heap an aperture is left open for the admission of air and for the escape of the volatile products; as the process goes on, these are closed, and new ones are made near the top and in other places, according as it is found desirable to check the progress in some parts and hasten it in others.

The heap is fired in the centre at the bottom, and the fire gradually spreads in all directions, but especially toward the apertures through which the air is admitted. Insufficient supply of air prevents thorough consumption of the wood, and a part of this must be sacrificed to obtain the necessary heat for expelling the volatile matters from the rest. The art of the charcoal maker consists in burning up as little wood as possible to produce the largest quantity of charcoal of nearly uniform quality. The first matters which escape are the aqueous vapors. They rise in the cover, making it moist, and pass off in a yellowish smoke. After these have disappeared the smoke becomes lighter, and then black and dense, emitting the pyroligneous acid, which grows stronger toward the end of the process. The carbonization is completed at the centre and top of

the heap, and gradually extends down its sides. In a heap half charred the finished portion is seen in the form of a reversed cone, the apex of which is at the bottom of the central axis of the heap. As the line between the finished and unfinished portions moves downward, the apertures for the admission of air should be kept in advance of it, the upper rows of holes being closed as the new ones are opened. The completion of each portion is indicated by the vapors changing from their black and dense appearance to a transparent light bluish color. The tarry matters, which collect mostly toward the close of the operation, run out in channels made beneath and around the heap. When the process is completed to the base of the heap all around, the openings are all closed, and the heap is left for one or two days, when it is partially uncovered, and the coal is drawn out, and spread around in thin layers. This is best done at night, when if any fire is still in the coal, it is quickly seen in the darkness. Whenever detected, it is quenched with water or wet sand or braise. The success of the operation depends wholly upon the experience, skill, and watchfulness of the collier. He must be always on his guard to prevent unequal falling in of the surface by too long continued action of the fire in any place, to prevent explosions, which sometimes occur from bad ventilation of the heaps, and to shield the heaps from the winds and rains. The wind blowing against them causes too great combustion on their sides, which is remedied only by closing the apertures and increasing the thickness and moisture of the covering. The time required for the operation varies with the size of the heap and the state of the weather. Small heaps may be charred in a week; large ones may require 8 weeks. A common yield is about 100 bushels to 3 cords of wood. Forty or even 50 bushels per cord are sometimes obtained. The condition of the wood, and the rapidity with which the process is conducted, are important considerations as affecting the yield. The more water present, the more heat is abstracted or fuel consumed to expel it. The aqueous vapor, moreover, as it passes over the coal already charred and highly heated, attacks this, converting a portion of it into carburetted hydrogen and carbonic oxide, which escape; by long continued charring at low temperature, this reaction and loss cannot occur. The more complete the seasoning, the better, then, the results. The advantage gained in this process by removing the bark as soon as the tree is felled, appears to be little appreciated. According to the experiments of Af Uhr, made in the districts where wood is coaled by the process above described in enclosed mounds, the loss of weight in pine wood deprived of its bark, and under cover in an open shed for 1 month, was .2458 of its original weight, while similar wood not barked, exposed with it, lost less than 1 per cent. in 4 months. The loss by rapid charring is shown in the following table, which presents

in the first 2 columns the weights of charcoal obtained from 100 parts of wood dried in air by Karsten; in the 3d, those obtained by Stolze from wood thoroughly dried at a temperature of 212°; and in the 4th, those of Winkler from wood dried in a hot room:

Manufacturers, who distil wood in close iron vessels for the sake of all the products, obtain in 100 parts by weight:

Charcoal.....	28 to 30
Acid and water.....	23 to 30
Tar.....	7 to 10
Gaseous compounds, and aqueous vapor.	37 to 30

They consume beside about 12½ parts of fuel outside of the retorts to produce the heat required. From these results, and from theoretical calculations as to the quantity of fuel necessary to produce the heat required to unite the oxygen and hydrogen in air-dried wood in the form of water, and to expel this by heating the charcoal to incandescence, it is apparent that no greater yield of carbon can be expected than that of 25 to 27 per cent. of the weight of the original material.—Other methods of producing charcoal require notice, as that in large brick ovens or kilns, and that in close retorts. The ovens for this purpose are constructed of various forms and sizes. A description, accompanied with a drawing, is given in the "American Journal of Science," vol. xvii. (1830), of one constructed by Mr. Isaac Doolittle, of Bennington, Vt., in 1829. It was 30 feet in diameter, 9 feet high, and of the capacity of 50 cords of wood. The product, he states, was uniformly from 55 to 60 bushels of coal to the cord. Rectangular kilns of this sort, holding 30 or 40 cords each, were not long after introduced at the iron works in the vicinity of Baltimore, upon the shores of the Chesapeake, and have since continued in successful operation. Pine wood is brought to them in vessels from the

forests around the bay. In these kilns are worked to great advantage the structures of this nature, and they are transported to localities where they are likely to soon become a desideratum. In the vicinity of the kilns, a question whether the charcoal is so dense and possesses so much strength as that prepared in the woods. In Massachusetts, where kilns of a certain size each have been in use, the product is estimated at 50 bushels to the cord; sometimes exceeded. Three cords are allowed from the fill to the cord. The cost of the process, including coaling, and discharging, is about 10 cents. Coaling in the woods by means of a cord when the wood is delivered in the form of 100 bushels.—Coaling in retorts is upon a comparatively small scale. The retorts are heated by an external fire, and the products are conveyed away in pipes condensed to obtain the pyroligneous acid, naphtha, &c. Though the process in the retorts is larger than the same quantity of wood is produced by other methods, the greater expense of condensation prevents its being adopted, and coal is the principal object. The volatile products is always obtained in this country has never been their preparation upon a large scale. Otherwise, these products have been in some instances obtained. —Peat charcoal is prepared in the same manner as wood charcoal, in a covered heap of circular or rectangular shape, or in ovens. As the peat is placed in channels of the size of a block, it is frequently left radiating from the heap. The peat is less compact, and the operation therefore requires such close attention; but if the peat is dried the process will go on very well, or the fire may go out. The volume of a heap may be 2,500 cubic feet, or 18½ tons of peat. The time of drying is cooled and ready for use in 14 days. The product is 100 feet of charcoal, weighing 100 lbs. The cost is estimated at about 25 cents, the raw peat being rated at 71 cents. Such is the experience at the works of Weierhammer in the vicinity of Weierhammer, where the process of carbonizing peat has been carried on to 450° F. has been carried on in another the torrefaction of the Irish peat company, which is subjected to dry distillation, and the volatile products is driven into a second furnace filled with wood, which is charred. The volatile products is driven into other apparatus, and condensed. From well-dried peat, a small way 40 per cent. of charcoal is obtained in good charcoal; and 49 of weight or 49 of bulk is obtained.

As the charcoal contains all the ash, a large ingredient in most varieties of properties are thereby much impaired; however so disposed to crumble, that it is for use as a fuel on the spot where it is. Still its heating power causes it to be ranked among the best kinds of fuel; for its use it is said to be preferable to coal. It is largely consumed in several parts of Europe for metallurgic purposes, as well in the blast furnace, both as regards quantity and the quality of pig iron. It is also employed in the reheating of iron in furnaces. In France, peat has been used together with fine bituminous coal, and a mixture of part charcoal and part coke is obtained which is described as a compact and strong material, admirably adapted for the purposes of steel and other similar operations. Charcoal, when thoroughly dry, possesses interesting properties in a remarkable degree. Noxious effluvia are entirely deprived of their power by passing them through a thin layer of charcoal. In the use of charcoal as fuel, it is applied for many other purposes. It is an essential ingredient in the composition of gunpowder; that of oak or alder being preferred for this purpose. When finely ground, it is used for polishing substances, for lining crucibles, for finishing the fine smooth surface of the moulds of castings, for making crayons, and by the use of it was used for making ink, which has never been surpassed for durability. This property withstanding the causes of change and deterioration possessed so eminently by charcoal, admirably fits it for many uses requiring durability. Stakes charred at the end are the most durable and convenient landmarks. Piers have been dug up in the Thames under the name which Tacitus describes as having been placed there by the ancient Britons to mark the passage of Julius Cæsar and his army. The antiseptic properties of charcoal make it a valuable material for preserving meats and articles of voyages, by burying them in it in close vessels. In the process of cementation coarsely ground charcoal is used to impart its carbonaceous properties to iron desired to be converted into steel. In medicine it is used as an antiseptic agent, being given internally in a powder, and applied externally as a dressing to wounds and ulcers. Charcoal made from coconut shell and from bread is said to be the best dentifrice known. When desired to be free from foreign matters, as for analytical purposes, charcoal may be purified by digesting it in dilute nitric or hydrochloric acid, and washing thoroughly with hot water.

**CHARD**, a municipal town, borough, and market town, Somersetshire, England, 13 m. from Bath, 140 m. from London, and 28½ m. from Exeter; pop. of the borough in 1851, 1,400. It is one of the Chard poor-law union, 26,085. The town is well built, on elevated ground, and contains a handsome parish church, and places

of worship for Baptists, Independents, and Wesleyan Methodists, an ancient town hall, formerly a chapel, an endowed grammar school, a national school, a large market place, a workhouse, a hospital founded in 1662 and rebuilt in 1841, and lace and woollen manufactories. There are also 2 iron founderies, and extensive warehouses on the wharf of the town, the latter being connected by a canal with Bridgewater. The troops of Charles I. suffered a defeat here under Col. Penruddock during the civil war.

**CHARDAK**, the Anava of Herodotus, supposed to be the salt lake Ascania mentioned by Arrian, a lake of Anatolia, 14 m. N. W. of the lake of Buldur, surrounded by high hills with steep and lofty cliffs, yielding much salt. Length about 20 m.; breadth from 2 to 4 m. At its W. end is the village of Ohardak.

**CHARDIN**, JEAN, a French merchant, born in Paris, Nov. 25, 1643, died in London, Jan. 15, 1713, went to the East to trade in jewellery, became the favorite purveyor of the shah of Persia, and eventually produced an admirable book of his travels and experiences in that country, which has been found true by subsequent travellers, and translated into many foreign languages. The London edition of 1686 contains only the description of his journey to Ispahan. Complete editions of the work, which is entitled *Journal du voyage du chevalier Chardin en Perse et aux Indes orientales, par la mer Noire et par la Colchide*, appeared in 1711 and 1735, and were followed by the most highly valued edition, brought out in Paris in 1811, by Langlès, the famous orientalist, who enriched it with a map, and with an abridged history of Persia. A Protestant by birth, Chardin was compelled on his return from the East in 1681 to seek refuge in England, where he was knighted and appointed agent of the East India company in Holland.

**CHARENTE**, an inland department of western France, formed principally out of the ancient province of Angoumois, deriving its name from the river Charente, by which it is drained; pop. in 1856, 378,721; chief town, Angoulême. The soil is generally far from being fertile. There are many shallow ponds, called *étangs*, some of them of considerable extent. Numerous caverns, some of great depth, are found, among which that of Rancogne, near La Rochefoucauld, is particularly remarkable. It seems as if earthquakes had been once frequent here; 2 rivers, the Tardouère and the Bandiat, the course of which is toward the Charente, disappear repeatedly, and finally are entirely lost before reaching that river. There are mines of iron, antimony, and lead; quarries of free and rag stone. The corn crop is poor, and scarcely sufficient for home consumption; but the vineyards, covering nearly 50,000 acres, yield a considerable surplus. Their produce is mostly converted into brandy, the superiority of that made at Cognac being universally acknowledged. Hemp, flax, and potatoes are extensively cultivated.

exterior commerce. There are several other navigable streams, and a canal from La Rochelle to Niort. The climate is agreeable; the surface is flat, and partly covered, especially in the neighborhood of the sea, with marshes yielding large quantities of salt. There are quarries of freestone; peat, and fine sand for the manufacture of glass, are also found. The soil is mostly calcareous or sandy, but nevertheless yields large crops of grain and wine. Large quantities of brandy are exported. Cattle, horses, and sheep are raised in great numbers. Oysters are sent to Paris and London. Sardines form an important branch of trade, and vessels are fitted out for the cod fishery. La Rochelle, Rochefort, and the other ports have a considerable share of the colonial and coasting trade of France. Salt is extensively manufactured along the coast. There are manufactories of coarse woollen stuffs, soap, fine earthenware, and glass, with tanneries and sugar refineries. Three islands, Oléron, Ré, and Aix, the first two somewhat considerable in extent, lie near the coast of this department, to which they belong. The average annual value of raw material employed in manufacturing is about

army sent to Byzantium again gave overwhelming evidence of competency, was replaced by Phocion to say, once more invested the city in command. In 338 he took part in the battle of Chæronea, the fatal issue of which to have been mainly due to him. The repeated appointment of him to command of the army of the Peloponnese, who, as Timotheus told to be a porter, can only be accounted for by the degeneracy of those then in power, with whom the athletic figure and flattery, and unscrupulous recklessness carried more influence than did many well-tried, brave, and able men. A Grecian statuary in the time of the celebrated statue known as the Colossus of Rhodes, was a native of Laodicea, a pupil of Lysippus, and flourished about the close of the 3d century B. C.

**CHARGE**, in military tactics, the advance of infantry or cavalry posing force, with the object of scattering the enemy's ranks before the attack. Charges of cavalry are either in order of battle, in a

With shouts precipitate themselves upon the enemy. If the charge fails to break the opposing line, the attacking force retires in as good order as may be, to re-form and repeat it, or to await another opportunity. If successful, and the enemy break before it, the attacking force must re-form, reload, fire on the fugitives, and continue thus to gain ground until the cavalry come up. An indiscreet pursuit might bring the pursuers under a flank fire or masked batteries, or within reach of the enemy's cavalry. (For charge in column, see ATTACK.) Infantry form square to receive the charge of cavalry. Cavalry charge in muraille, echelon, or column. Echelon has the advantage of exposing the troops less. Charge in column is employed against infantry deployed in masses. In such case, the cavalry form in columns by squadrons, and advance, first at march, then at trot, increasing in speed to the wild gallop with which they hurl themselves on the foe. The squadron at the head of the column receives the fire, and, if it can penetrate the square, the succeeding squadrons complete the defeat. If, on the contrary, it fails to make impression on the wall of bayonets, it breaks to the right and left to mask the other squadrons, who ought to charge ere the infantry can reload. A skilful commander will endeavor to draw the enemy's fire on skirmishers, or on a curtain of light infantry, and seize the moment after the pieces are discharged to urge his charge. On the other hand, the officer in command of the infantry must be on his guard against such feints. Coolness, steadiness, and the most perfect discipline are the qualities which enable infantry to sustain cavalry charges. When the infantry fire is reserved and delivered with precision at the breasts of the attacking squadron, the first rank of men and horse are usually overthrown, and form a rampart which embarrasses the attack of the squadrons following. The passage of defiles in retreat should be always secured by a charge of cavalry. In charging artillery, it is necessary first to defeat the troops that support it. When pieces are isolated, cavalry form a crescent having the hollow toward the fire, and, advancing the points or horns of the figure till they arrive beyond the side range, they dash on the battery and sabre the gunners. Troopers usually cheer when they attack, but sometimes charges have been made in silence. In the days of chivalry the charge consisted of individual tilts of knights and men-at-arms. Later, the cavalry on both sides approached to 80 paces, where they exchanged pistol fire, and the party which suffered most retired. Yet later, they advanced to 30 paces, fired, and took to their sabres. Frederic the Great was the first who ordered his men to charge sabre in hand, commencing the gallop at 50 paces. Single charges have often decided battles. At Eylau, the whole French cavalry under the duke of Berg charged at once on the enemy, with a momentum that overthrew the Russian horse and penetrated two lines of in-

fantry. During the French retreat in Spain, at Medellin, on the Guadiana, Gen. Latour ordered a charge on the pursuing Spaniards with such effect that he put 15,000 of them *hors de combat*, and took 6,000 prisoners and 40 guns. A main feature of Napoleon's tactics was a grand charge of the cuirassiers and heavy cavalry of the reserve. It failed him, however, at Waterloo. The history of warfare abounds in records of brilliant charges, few pitched battles being fought without one or more worthy of commemoration. The charge of the British light cavalry at Balaklava, against a force which it was madness to encounter, is the most recent instance. (See BALAKLAVA, and CAVALRY.)

CHARGE D'AFFAIRES, the title of the 4th rank of diplomatic agents. They are accredited not to the sovereign but to the department of foreign affairs, and are appointed by and responsible to the minister of state of their own country. They were not recognized in European diplomacy till near the 18th century. By the congress of Vienna in 1815, they were made the 8d order of diplomatists, which was changed to the 4th by the congress of Aix la Chapelle in 1818. The title is given to the agent whom an ambassador or envoy, by virtue of authority from his prince or state, appoints to conduct in his absence the affairs of his mission.

CHARIKAR, a town of Afghanistan, pop. 5,000, containing a castle, the residence of a local chief. It has an active commerce in coarse cotton goods, and a carrying trade of some importance across the Hindoo Koosh. In 1841 it was the seat of a British garrison, afterward almost wholly destroyed in its retreat to Cabool.

CHARIOT, among ancient nations, a two-wheeled carriage, open above and behind and closed in front, and used in war, in public games, and for the purposes of common life. The axle of the Greek chariot was usually made of oak, ash, or elm, though Homer describes the chariots of Juno and Neptune as having metallic axles. The wheels were about 4 feet in diameter, and each consisted of a nave bound with an iron ring, of 10 spokes, a felly of elastic wood, and an iron tire. They were fastened to the axle by pins, and the overthrow of Glaucomas in his contest with Pelops was caused by the treachery of his charioteer, who inserted a linchpin of wax. The Lydians and Romans sometimes attached 2 or 3 poles and spans of horses to their chariots, but the Greeks rarely added a third horse. From the earliest historic periods chariots were used in war both by the Asiatic and the classic nations. The famous scythe chariots, whose spokes were armed with long hooks and sickles, were chiefly used by the ancient Persians, Britons, and Gauls. The warriors of highest rank among the Greeks, Romans, and Jews, either fought from their chariots, or sometimes in close combat, dismounted. In the Roman games chariots were often decorated with sculptures and enriched with gold and ivory. The triumphal chariot,

follows a S. course to the Missouri river, which it joins near the S. extremity of Chariton co., Mo. It is about 250 m. long, and is navigable for 50 m. The E. Chariton and Middle fork are its principal branches.

CHARITON, a county in the N. central part of Mo., derives its name from the Chariton river, by which it is intersected. It is bounded W. by Grand river, and S. W. by the Missouri. It is also drained by Yellow and Wolf creeks, which furnish water power for several mills. The soil is fertile and adapted to pasturage. The surface is gently undulating and covered with forests and prairies. Stone coal and limestone are found in large quantities. In 1850 this county produced 2,667,908 lbs. of tobacco, 377,397 bushels of corn, 14,592 of wheat, and 34,170 of oats. It contained 12 churches and 1 newspaper establishment. There were 1,000 pupils attending public schools, and 500 attending academies or other schools. Pop. in 1856, 9,211, of whom 2,198 were slaves. Capital, Kaytesville.

CHARITY, BROTHERS OF. I. An order of religious hospitallers founded at the end of the 13th century, and since denominated Billelines. II. A religious order in the Roman Ca-

lar institutions in other countries, of charity are now to be found in civilized land. Louis XIV. granted to this institution in 1657, finally confirmed by the legate in 1660. The charity and devotion men had made them so useful that even the revolution spared continued their work of benefices without restraint. One of the first new government was to open to usefulness, and Napoleon placed under protection of his mother. They vows, which are renewed every year 1848 the number of establishments of charity throughout the United States not included, was under the charge of about 12,000 American branch of this society established at Emmitsburg, Md. Mrs. Eliza Seton, their first superior. In 1852 there were 28 houses of the sisters in different parts of the States, and the number is constantly increasing. In the diocese of New York, 11,250 sisters of charity. having an

In occasions during the night before the of the wedded pair, with all sorts of pans, kettles, and iron and copper utensils (*chalybeities*), producing every variety of discordant sounds, and accompanying them with derisive and obscene songs. The charivarists usually continued their uproar until their wrath was soothed by drink or food. The council of the town attempted to put a stop to this nuisance, but frequently occasioned disturbances. In French towns, as for instance in Lyons, this practice was maintained as late as the 17th century. In Brittany the term charivari was also applied to aggravated collisions between husband and wife. Xantippe throwing a pail of water at the head of Socrates is the most classic type of this sort. In the 16th century of France the turn of 4 queens is called charivari. The Germans possess a work on the origin of *Katzenmusiken* by Phillip, which appeared at Freiburg in 1849. French literature boasts of a still more comprehensive work on the same subject: *Histoire, morale, civile, politique, et littéraire, du charivari, depuis son origine vers le 4me siècle*, by Dr. Ybariat de St. Flour, with a supplement by Eldi Christophe Bassinet, which brings the historical record of charivaris down to the 18th century.

CHARIZI, JUDAH, one of the most remarkable Hebrew scholars and poets of his day, born in Xeres, in Spain, time unknown, died before 1600. Little is known of his life. He received his education at one of the rabbinical schools for which Spain was so celebrated in the middle ages. Although he was one of the restorers of Hebrew literature, his writings were strongly tinged with the genius of Arabic poetry, which he had studied with great care. He translated the philosophical works of Maimonides and the poems of Hariri from the Arabic into Hebrew, and composed a Hebrew imitation of the latter, entitled *Tahkemoni*, which is one of the curiosities of literature.

CHARLEMAGNE, EMPEROR OF THE WEST. See CHARLES I. (GERMANY.)

CHARLEMAGNE, JEAN ARMAND, a Frenchman, born Nov. 30, 1759, died in Paris, March 6, 1838, who left the study of theology to become successively attorney's clerk, soldier, writer on agricultural subjects and political economy, and finally actor and dramatist. The most popular of his plays was one entitled *Le souper des Jacobins*. He was also the author of several novels; that entitled *Timon Alceste, ou le misanthrope moderne*, was commonly attributed to him, but was written by another person of the name of Charlemagne.

CHARLEMONT. See GIVET.

CHARLEROI, or CHARLEROY, a Belgian arrondissement, in the province of Hainaut; pop. increased from 131,025 in 1846 to 170,824 in 1857. Charleroi, or Charleroy, the fortified chief town of the arrondissement, is situated on the Sambre, on the railroad from Brussels to Namur, 88 m. from the former city, and since 1856 con-

nected with Paris by the Northern railroad via Maubeuge and St. Quentin. There is also a railroad from Louvain to Charleroi; the Sambre and Meuse railroad branches south of Charleroi; and via Erquelinnes the town connects with the Paris and Cologne railroad. Thus accessible from all parts, the town is in a very flourishing condition. The glass works here are the most extensive in Belgium. The annual yield of the collieries in the vicinity, which give employment to 8,845 miners and 118 steam engines, is estimated at 3,000,000 cwt. There are about 6,000 nail-makers in the adjoining country, and 70 high furnaces, 50 iron foundries, and 90 coal pits, almost all of which have sprung into existence within the last 30 years. There are also tanneries, dyeing establishments, rope-walks, salt and sugar refineries, and factories for spinning wool. The fortress was commenced by Charles II. of Spain, in 1666, and completed by Vauban for Louis XIV. It is a hexagon, with 5 counterscarps, 2 horn-works, and 5 ravelins. It has changed masters several times, and in 1794 stood a vigorous siege, and held out until all the advanced works were levelled with the ground, and until 4 assaults had been made by the French, when it capitulated. It was restored in 1816 under the direction of the duke of Wellington.

CHARLES, a S. W. co. of Md., separated from Va. by the Potomac river; area 450 sq. m.; pop. in 1850, 16,162, of whom 9,584 were slaves. The surface is uneven and the soil rather inferior. The forests consist mainly of oak, chestnut, ash, cedar, and locust trees. In 1850 this county produced 458,684 bushels of corn, 149,588 of wheat, 25,684 of oats, and 2,862,800 pounds of tobacco. There were 23 churches, and 784 pupils attending the public schools. The first settlement in Charles co. was made in 1640. Capital, Port Tobacco.

CHARLES. The sovereigns of this name will be treated according to the alphabetical order of the countries over which they ruled, viz.: 1, England; 2, France; 3, Germany; 4, Naples; 5, Sardinia; 6, Spain; 7, Sweden.

#### I. ENGLAND.

CHARLES I., the second of the house of Stuart who sat on the English throne, was the 8d son of James VI. of Scotland and I. of England, and Anne, daughter of Frederic II. king of Denmark; born at Dunfermline, in Fifeshire, North Britain, Nov. 19, 1600, previous to the accession of his father to the throne of England; became heir apparent to the crown on the death of his elder brother, Prince Henry, in 1612; was created prince of Wales in 1616; succeeded to the British throne on the demise of his father in 1625; and was executed Jan 30, 1649. At an early age he was thrown into that fatal association with worthless favorites, which seems to have been the bane of his house. In the beginning of the year 1623, a marriage had been negotiated at the court of Spain, principally by means of the earl of Bristol, the English

"of all the proceedings connected with the Spanish match, it may be fairly inferred: 1st, that had the treaty been left to the address and perseverance of the earl of Bristol, it would have been brought to the conclusion which James so earnestly desired; 2d, that the Spanish council had ministered ample cause of offence to the young prince by their vexatious delays and their attempts to take advantage of his presence; 3d, that he, nevertheless, entered spontaneously into solemn engagements from which he could not afterward recede without the breach of his word; 4th, and that, in order to vindicate his conduct in the eyes of the English public, he was compelled to employ misrepresentation and falsehood. But the great misfortune was the baneful influence which such proceedings had on his character. He was taught to intrigue, to dissemble, to deceive. His subjects, soon after he mounted the throne, discovered the insincerity of their prince; they lost all confidence in his professions; and to this distrust may in a great measure be ascribed the civil war which ensued, and the evils which befell both the nation and the sovereign." It is worthy of remark, that when, shortly after

of evil consequences to both him and the wife of Buckingham to say the least, as fatal to Charles as were the teachings that minister, and the animosity the crown, among the common Charles I., though he had extraordinary accomplishment, and a calm, which obtained for him the credit of wisdom than he possessed, had of perception nor depth of insight, slow, formal, destitute of power to convince, and, when he was persuaded, inaccessible to persuasion, that long before Buckingham to shape his faculties, he had not been tutored, and heard nothing of prudence or in his father's court, but daily, the propriety of obtaining means however false or dishonest what James loved to call the His position, moreover, was as came to the throne, no one but his shining faculties, of the clearest the soundest judgment, the will, the most thorough wisdom

the part of Charles; nor was the propriety by such means as he could withhold, by benevolences, loans, extortions and that would be tolerated, any new in the part of kings, or any greater aim than it had been in his father, or Elizabeth, or in Henry VIII., or in I., every one of whom had regarded it as a necessary evil, to be endured if it could not be avoided, to be dishonour as long as, and whenever, it was possible. All had avoided summoning a parliament when government could not be carried on without them; all had at times carried on business snubbed, and whenever they dared to do so. Each one of them, unless it were James, had committed far grosser abuses of privilege, without their raising so much a murmur of discontent, than Charles had. His principal error seems to be, that he invariably made concessions which ought to have been firm, and was intransigent when he ought to have made concessions; his chief fault, that no one could be his friend or enemy; that he never kept any promise, either of support to the friends of amnesty to the other; so that his defeat headed his victory almost as much as his defeat, for they knew that no promise could withhold him, if successful, from abuse of success. At the opening of his reign, in war with Spain, and wanting money to carry it, he was compelled to summon a parliament, which, as soon as it met, began to present grievances, and proceeded to impeach the Duke of Buckingham, without granting any redress. To avoid sacrificing his favorite, the king dissolved the parliament, quarrelled with the lords as well as with the commons, expelled 2 members, Digges and Eliot, and others, Bristol and Arundel, to the tower. Identically at the instigation of Buckingham coincided with his naturally arbitrary yielding, and hasty temper, that, being engaged in hostilities with Spain, which he did not hope to prosecute successfully without the aid of his parliament, he plunged into a foreign and a wholly unnecessary war with France and proceeded to carry on both by forced loans and expedients undeniable, as they were odious to the people of England.

Two years afterward, a second parliament was summoned, and again adjourned, in order to prevent Buckingham from being impeached by vote the "grievance of grievances," the chief cause of all the calamities of the reign.

On the following day it was proposed to the king, after giving the royal assent to the bills of subsidy; but not until it had received the petition of right, to which the people appealed as to their chief protection against the encroachments of the prerogative, which the crown was ultimately forced to grant. In the mean time, the English arms were covered with disgrace; yet still the king persisted in retaining Buckingham at the head

both of his councils and of his army; and that favorite was on the point of again setting sail from Portsmouth, in all probability to bring fresh discredit to the English fleet and army, when his career was cut short by the dagger of a fanatical assassin, Felton, in time to save the military prestige of his country from further degradation, but not to spare his king the universal odium and distrust of the nation. Almost immediately after the death of Buckingham, Rochelle, for the relief of which the war with France had been nominally, at least, undertaken, surrendered, and the last stronghold of Protestantism in France, and one of its strongest bulwarks throughout the whole world, had ceased to exist, the blame and disgrace of its fall both resting wholly upon Charles; who, if he could have at this stage of proceedings consented to a few necessary and moderate reforms, and would have set himself at the head of a Protestant movement, would have been supported by his people to almost any extent, and might have become as popular as he was ever afterward odious throughout the realm. At this moment, in thoroughly ill humor, the parliament reassembled; and, although ordered by the royal message to take the bill for tonnage and poundage into immediate consideration, proceeded to take up the grievances, religious and political, of the community, the former having the precedence, owing to the increasing influence of the Puritan party. The king was now guilty of a piece of mean and dishonest sophistry and trickery, which cannot be explained or understood, in substituting for the petition of right, which had passed into a law and had received the royal assent, a garbled edition from which the assent had been removed, and the evasive answer which he had been compelled to cancel in the last session attached to it instead. The house was outraged. Charles himself, repenting of his folly, would, if he could, have laid the storm he had raised. But it was too late. The commons proceeded to the strongest measures. The speaker endeavored to adjourn the house, in obedience to an order he had received from the king. They again refused to adjourn, and ordered the speaker to put to the vote a remonstrance against the bill of tonnage and poundage; and when he refused to do so and arose to depart, he was held down by force in his chair by Holles and Valentine, while the former delivered an extraordinary and violent protest, declaring all persons enemies to the country who should attempt to bring in Popery, Arminianism, or other doctrines obnoxious to the true and orthodox church; who should advise the taking tonnage or poundage; or who should pay tonnage or poundage, the same not being granted by parliament. This done, they adjourned themselves just in time to prevent the doors of the house from being forced by the captain of the guard; and the next morning the parliament was dissolved by the king in the house of lords, without sending for the commons. How far the

parliamentary freedom, for he had in the first instance some reasonable cause of complaint, any more than he must accredit to the parliament the determination to make of the king a mere puppet of their will. Both designs arose soon after, and on both sides with nearly equal injustice. Thus far, it is nearly certain that each side honestly believed itself to be clearly and indisputably in the right; while one of them, the king, was, though it was perhaps impossible that he should then perceive it, almost wholly in the wrong. It was but a short time before he made himself so entirely. Nine members of the lower house were now arrested, and being brought up by writ of habeas corpus must, in conformity with the petition of right, have been discharged or admitted to bail, when Charles most unwarrantably placed them in the hands of the lieutenant of the tower, and forbade him to produce them in court. Subsequently, they were offered their discharge on bail on their giving security for good behavior, which they refused, as such a proceeding would imply a confession of guilt. Thereafter they were ordered to plead to a criminal information filed against them, to which they objected that the court of king's bench had no authority to sit in judgment on their conduct in parliament, which objection was most sophistically overruled, on the ground that their behavior was extra-parliamentary, and therefore liable to censure *extra parlamentum*. Whereupon 3 of them, the most obnoxious, Eliot, Holles, and Valentine, were imprisoned during the royal pleasure, and ordered, before liberation, to make submission and pay fines to the king, respectively, of £2,000, £1,000, and £500. Eliot died in the tower, of disease aggravated by confinement, refusing to make submission, and being refused any mitigation of his penalty until he should do so, in 1632, after 3 years' rigorous imprisonment. He was considered a martyr for the sake of liberty and justice, and it would be hard to say whether the conduct of Charles was more impolitic or more unworthy. He violated not only the established privileges of parliament,

put himself so thoroughly in the wrong, that he had silenced all his own friends, and filled every person in the land with the gravest and darkest suspicions. Nor was it to be denied that if the royal prerogative had gone beyond the limits of constitution, the conduct of Buckingham would justify in our days a suspension of confidence, and the refusal to resign until a change of ministry. However, as yet the practice, as well as the established privileges of parliament, Charles now, as if resolved to go to the utmost, not only declared by proclamation his intention to govern without parliament; he did so for no less than 11 years; he gave the church entirely to the king, and the state into the hands of the king. Wentworth, created earl of Strafford, severally promised him to use all his power to render him absolute in the government. By the extraordinary assumptions of Charles, the Parliament were led to believe that Charles was bent on reintroducing the tyranny of Rome; and although the king was true, yet, knowing that it could be blamed but they, for persistent conduct which could but aggravate it. Ireland, in the mean time, under the government of Wentworth, who was to raise money in order to meet the exigencies without resorting to parliament, was driven to the very limits of Scotland, maddened by the king, the instigation of Laud, to set upon her contrary to the laws of the kingdom, actually rose in England, gained possession of Lancashire and Durham, the king having attempted to raise funds to oppose the summoning a parliament, of which he refused supplies, but which, as it passed

first to consider grievances, he dissolved within 20 days after its assembling, before it had given any positive reply to his demand. The lords were in his favor; and clearly he was too precipitate, for had the commons refused him any aid, most men would have deemed the dissolution justifiable; had they granted any, even the smallest, the Scots would have been deterred from their attempt. At this time Charles had a superb fleet of above 60 ships at sea, which he maintained by the illegal levy of ship money; but army he had none on which he could depend, nor any means to raise one. Wherefore, unless he would see the Scots march to York and take possession of the northern metropolis, there was no resource but to convoke the great council of the peers at York, who immediately demanded the assembling of the parliament and to treat with the Scottish rebels. In 1640 assembled the parliament which did so much, in the first instance, for the liberties of England, and afterward was guilty of such odious usurpation, known in history as the long parliament. Its first act was to impeach and then to proceed by attainder against both Laud and Strafford, the latter of whom was condemned and executed, abandoned by the king, for whom he had made great sacrifices. Some just and salutary laws were passed by this parliament; some illegal practices, which had been usual with the later English monarchs, were repressed; some grievances redressed; some rights of the subject firmly established; but, from the moment when it voted itself incapable of dissolution, the parliament changed places with the king; became distinctly the usurping power; made infinitely greater attacks, both on the prerogative of the crown and on the rights of the individual, than the most despotic of kings had ever attempted; arrogated to itself the power of regulating every thing in the realm, from the highest to the lowest; constituted itself a court of law, a court of justice, and a court of morals, exercising powers the most unheard of, and, in fact, altering the whole constitution of England from a monarchy into a perfect democracy, of which itself was the indefeasible and the sole exponent and ruler, until it should think proper to abdicate its own authority and descend from supreme despotism into private life, which no one supposed it ever would do, and, in fact, which it never did. An appeal to arms was now necessary, if England was to be a monarchy; for, as the king truly said, he might be called king, and be served on the knee, but he should be no more king than the meanest of his subjects, should he concede all that was now asked of him. Had he conceded a little on his first accession, he might, probably, have been the most popular king in Europe. Then he would concede nothing, and had irritated all his enemies to madness. When the head of Strafford was asked of him, and every reason of expediency, honor, faith, commanded him to be firm, he yielded. Now he was tied to the stake, and

could but fight with what weapons he had left to him. He set up his standard at Nottingham, Aug. 22, 1642; but the parliament was really in arms the first, and Col. Cromwell, at the head of a troop of horse, had seized the plate of the university of Cambridge, which would otherwise have gone to arm and equip men for the king. The first blood was shed at Edgehill (Oct. 23), where, as in all the first actions of the war, the high spirit and chivalrous courage of the undisciplined cavaliers prevailed over the inferior strength, spirit, and enthusiasm of their equally undisciplined antagonists. It is certain that, after the battle of Reading (April 26, 1643), and the advance to Brentford, London might have been taken, and the war concluded at a blow, but that the royalists, who had perceived by the pretensions of the king in the late negotiations at Oxford that he had abated nothing of his despotic intents, dared not allow him to prevail. The remodelling of the parliamentary army followed; Cromwell and Fairfax became its generals; the former introduced a discipline as perfect as is known in any modern service, and created a spirit of enthusiastic fanaticism, equal to the spirit of enthusiastic loyalty and chivalry which animated the cavaliers; and by the union of the two, raised the late despised parliamentarians to be, what they proved themselves thereafter in every European country, the best troops in the world. Marston Moor (July 3, 1644) and Naseby (June 14, 1645) followed; the last blow was struck by Sir Jacob Astley, for the crown, at Stow-on-the-Wold (March 21, 1646), when he told his captors: "My masters, you have done your work, and may now go play, unless you please now to fall out among yourselves." After some attempts at negotiation, marked by his usual insincerity and chicanery, with the leaders of the parliament and the leaders of the army, neither of whom he chose to trust, while neither dared to trust him, Charles delivered himself up to the Scots, May 5, 1646, who, on Jan. 30, 1647, gave him up to the commissioners of the English parliament. Cromwell, who as yet entertained no definite views, nor saw any way of attaining the great elevation which he subsequently reached, was prepared to play the part subsequently played by Monk; and Fairfax, who was a truly upright and honorable man, and averse to all extreme courses, was ready to support him. Yet, even now, when terms were offered him by the Independents, so advantageous that Sir John Berkeley, one of his truest adherents, declared that "a crown so near lost was never yet so easily recovered as this would be, were things adjusted on these terms," the king madly refused to concede any thing, broke off all terms with the army, commenced new negotiations with the Presbyterians, and ultimately convinced both parties—all parties—that there was no truth in him. The discovery of a fatal letter to his wife, in which he assured her that he designed for those rogues, Ireton and Cromwell, no reward but that "for a silken garter, they should be fitted with a hempen rope," destroyed

tence of death was passed upon him, Jan. 27, and he was executed by decapitation on a scaffold erected in front of the banqueting house at Whitehall, Jan. 30, at 3 P. M.—Charles I. had 8 children by Queen Henrietta, 6 of whom survived him, viz.: Charles and James, afterward kings of England; Henry, duke of Gloucester; Mary, the wife of William, prince of Orange, and the mother of William, king of England; Elizabeth, born 1635, who died a prisoner in Oaribrooke castle soon after her father's death, Sept. 8, 1650; and Henrietta Maria, the wife of Philip, duke of Orleans, from whom, through a daughter, is descended the royal family of Sardinia. Charles was an elegant writer of English, and, in the early part of his reign, a zealous patron of the fine arts.—The writings attributed to him are indicated in Horace Walpole's "Royal and Noble Authors," and have been published under the title of *Reliquiæ Sacre Carolinæ*. Among them is the famous work, the *Eikon Basilike*, or "Portraiture of his Sacred Majesty in his Solitudes and Sufferings;" his claim to its authorship has been much disputed, though advocated by the Rev. Dr. Christopher Wordsworth, in his book enti-

reached him in Brussels. In order to avail himself of the confusion in England after the downfall of Cromwell's government, Charles fled to Calais in Aug. 1659, but in April, 1660, that he succeeded at Breda in opening a negotiation with the Monk. His restoration to the throne was voted by parliament a year, and on May 8 he was proclaimed in London, which city he entered in triumph, having departed from the Hague 6 days. His journey to London was one of triumph; and the whole of the celebration which it passed bore the appearance of a fair-day. So great was the popularity with which Charles was received, with his usual wit, he observed to his company, that he could not tell him why he had stayed away so long; every body seemed so charmed with him that he was at length come back. He returned with open arms, reinstated with the promise to give a guarantee, or to make good. "It has been," says Macaulay of much the practice of writers, a

tion of the soldiers was the first object of enlightened patriot; but it was an object while the soldiers were united, the most he could scarcely expect to attain. On an, a gleam of hope appeared. General proposed to general, army to army. On which might be made of that one moment depended the future destiny of mon. Our ancestors used that moment. They forgot old injuries, waived petty is, adjourned to a more convenient opportunity all dispute about the reforms which institutions needed, and stood together, rs and roundheads, Episcopalians and terians, in firm union for the old laws of d against military despotism. The extinction of power among king, lords, and ns might well be postponed, until it had decided whether England should be gov- by king, lords, and commons, or by iers and pikemen." The reign of Charles arked by disasters and disgraces of all

The Dutch fleets not only swept the l, but entered the Thames, burned the and dockyards at Chatham, and terrified izens of London, but maddened even han they terrified them with the roar of cannon. A frightful conflagration destroyed e city of London; a hideous plague de- ted whole districts. The name and er of Englishman, abroad, had sunk to rest state from the proud preëminence it had occupied during the stern domi- of the great protector. The whole of this most brilliant and amiable—whom his enemies could not hate—but most ees and purposeless of all the Stuarts, t one general saturnalia and grand orgie e, licentiousness, meanness, and riot. d May 21, 1662, to a virtuous and amiable uese princess, Catharine of Braganza, er of John IV., he outraged, neglected, ured her in the tenderest point, encourag- harem to insult her before his face.

to maintain Protestantism, he signed t treaty at Dover by which he pledged f to make public profession of the Catholic religion, to join his arms to of Louis XIV. for the purpose of destroy- e power of the United Provinces, and oloy the whole strength of England by nd sea in support of the rights of the of Bourbon to the vast monarchy of Louis, on the other hand, engaging to arge subsidy, and promising that if any ction should break out in England he send an army at his own charge to sup- s ally. This treaty was signed at Dover

in May, 1670, just 10 years after the day on which Charles landed at that very port amid the acclamations and joyful tears of a too confiding people. His scheme was frustrated by the refusal of the commons to grant him supplies for the war, and by their compelling him to dismiss his ministry, Clifford, Arlington, Buckingham, Ashley, and Lauderdale, of the initial letters of whose names is composed the well-known enigmatic cipher, cabal. An alliance with France brought about a quarrel with Holland. War against that country was declared in 1672 (March 17), but the indignation of the people being aroused by the proceedings of the government, the prime minister, Shaftesbury, retired from the cabinet, and Charles was compelled to make peace with Holland at the beginning of 1674 (Feb. 28). The excitement produced by the so-called popish plot, in 1678, led Charles to the fatal step of dissolving the parliament. The first of the 8 parliaments which he afterward successively called, met in March, 1679, and was noted for passing the habeas corpus act. The last of them was summoned to meet at Oxford, March 21, 1681, but proving as little compliant as the two preceding, he dissolved it, after a week's session. From that year Charles governed without a parliament, and his arbitrary course at length provoked the Rye-house plot, June 14, 1688, instigated by friends of constitutional liberty. The detection of the plot brought the noble heads of Lord Russell and Algernon Sidney upon the block; and Charles's reign, thus stained with the blood of these martyrs of liberty, was soon brought to a close. He died suddenly of apoplexy, and his death, as usual in that age, although without the smallest shadow of grounds, was attributed to poison. When he was almost *in articulo mortis* he declared himself a Roman Catholic, and received extreme unction, and the last rites of the church, at the hands of a proscribed priest, Father Huddleston, who was introduced by a secret passage, in disguise, into the royal bedchamber.—The following sketch of his character, by Macaulay, is almost an epitome of his reign: "He had received from nature excellent parts and a happy temper. His education had been such as might have been expected to develop his understanding, and to form him to the practice of every public and private virtue. He had passed through all varieties of fortune, and had seen both sides of human nature. He had, while very young, been driven forth from a palace to a life of exile, penury, and danger. He had, at the age when the mind and body are in the highest perfection, and when the effervescence of boyish passions should have subsided, been recalled from his wanderings to wear a crown. He had been taught by bitter experience how much baseness, perfidy, and ingratitude may lie hid under the obsequious demeanor of courtiers. He had found, on the other hand, in the huts of the forest, true nobility of soul. When wealth was offered to any who would betray him, when

cared very little what they thought of him. Honor and shame were scarcely more to him than light and darkness to the blind. His contempt of flattery has been highly commended, but seems, when viewed in connection with the rest of his character, to deserve no commendation. It is possible to be below flattery, as well as to be above it. One who trusts nobody will not trust sycophants. One who does not value real glory, will not value its counterfeit. . . . The facility of Charles was such as has, perhaps, never been found in any man of equal sense. He was a slave without being a dupe. Worthless men and women, to the very bottom of whose hearts he saw, and whom he knew to be destitute of affection for him, and undeserving of his confidence, could easily wheedle him out of titles, places, domains, state secrets, and pardons. He bestowed much; yet he neither enjoyed the pleasure nor acquired the fame of beneficence. He never gave spontaneously; but it was painful to him to refuse. The consequence was, that his bounty generally went, not to those who deserved it, nor even to those whom he liked the best, but to the most shameless and importunate suitor who could obtain an

#### II. FRANCE.

CHARLES MARTEL, duke and mayor of the palace of the Franks in 689, died in 741, was the son of Pepin of Herstal, by his

vor of the palace to the young king Dagobert III. The Franks were thus ruled by a king in the name of 2 children. This could not be endured; and the Neustrians first rose against Plectruda, and the Austrasians freed Charles from prison, and proclaimed him their duke. Under his command they invaded Neustria, gained several victories, and induced their western brothers to acknowledge the authority of their leader. Thus Charles became sole lord of both kingdoms, permitting nevertheless the nominal reign of Clotaire IV., Dagobert III., Chilperic II., and Thierry IV. This continued from 716 to 737. But on the death of the last, Charles appointed no successor and retained the supreme power, although not assuming any higher title than that of duke of the Franks. His energetic government at home subdued the powerful Austrasian aristocracy to submit, as well as the prelates of Neustria and Burgundy, while his valor enlarged the extent of the Frankish kingdom. He waged successful wars against several German nations; and his brightest laurel was won in his struggle against the Moslems, who, after the conquest of Spain, had crossed the Pyrénées and attempted to conquer Gaul also. The southern part of this country had been first successfully protected by the gallant Eudes, duke of Aquitaine, who had even routed the Moslems in 721 at a great battle under the walls of Toulouse; but, overpowered by the immense forces of the invaders, he was eventually compelled to call for assistance upon the duke of the Franks. The Moslems had already penetrated as far as Poitiers, when Charles at the head of his Frankish and German warriors met them a few miles N. E. of that city. Both armies stopped, and passed 6 days in desultory skirmishes before engaging in a decisive battle. At last, on Oct. 3, 732, the powerful masses of Christian infantry received the charge of the Arabian cavalry, and, "fighting with breasts as firm ramparts and with iron arms," withstood unbroken its repeated assaults until at sunset the Saracens retired to their camp. In the confusion and despair of the night the various tribes of the Orient, Africa, and Spain were provoked to attack each other, and the remains of the host were suddenly dissolved, every emir seeking safety by a precipitate flight. At sunrise the Franks to their unbounded astonishment perceived that the enemy had left their camp and were retreating in haste toward the south. The Moslems had not dared to encounter again such formidable warriors. This victory, which took place 100 years after the death of Mohammed, checked the power of his adherents and saved western Europe from their further invasions. Charles, from his conduct on this great occasion and the vigor of his arm, received the surname of Martel, the "hammer" of the Moslems. His prudence prevented him from pursuing the retreating army; but he subsequently renewed the war, and forced the Arabian emirs, who had maintained their

power over several cities of southern Gaul, to return to Spain. The whole of Aquitania was annexed to the Frankish empire, which was ruled by Charles, and after his death divided between his 2 sons, giving Austrasia to Carloman and Neustria to Pepin. The latter soon became possessed of the whole, and afterward assumed the title of king, being the first of the Carolingian dynasty.

CHARLES I. (CHARLEMAGNE). See CHARLES I. OF GERMANY.

CHARLES II. (THE BALD), the 4th king of the Carolingian dynasty, born June 12, 823, at Frankfort-on-the-Main, died Oct. 12, 877, in a village at the foot of Mount Cenia. The son of Louis le Débonnaire by his 2d wife, Judith of Bavaria, his birth gave rise to serious troubles between his father and his elder brothers. War followed, in which the old Louis le Débonnaire was harshly dealt with by his ungrateful sons; and his death, June 20, 840, found Charles holding nearly the whole western part of his father's empire. His claim being, however, disputed by his eldest brother Lothaire, who had assumed the imperial dignity, Charles, to maintain his rights, formed with his 2d brother Louis, king of Bavaria, an aggressive alliance against the emperor, and defeated him in a desperate battle fought June 25, 841, at Fontenay or Fontenoy, in Burgundy. The victory, however, weakened their resources to such an extent as to prevent them from following it up. Charles and Louis renewed their alliance in a solemn meeting at Strasbourg, Charles taking an oath in the German language, and Louis in the vernacular of the people of Gaul. The words of this oath, which have been preserved, are the first monument of the Romance language, from which the French has sprung. The union of Charles and Louis brought Lothaire to terms; and the treaty of Verdun in 843 secured to the former the tenure of his kingdom, that is, the whole of Gaul W. of the Meuse, the Saône, and the Rhône, which henceforth was to be called France, and part of Spain N. of the Ebro. But the submission of all the provinces of this kingdom was far from being complete, and Charles had frequently to resort to arms against the people of Brittany and Aquitania. Under his reign the Normans, who had previously desolated the coasts of Gaul, invaded the country by ascending the rivers, burning and plundering the villages and the cities. Paris itself had to suffer by their ravages, Charles being unable to afford protection against them. On the death of his nephew, the emperor Louis II., Aug. 12, 875, Charles seized upon the imperial crown; but his power seems to have been rather diminished by this assumption of a new title. A few months later he was compelled to sign a decree by which the tenure of the counties was declared hereditary, which decree was the foundation of the feudal system in France. This was the last important act of his otherwise inglorious reign.

CHARLES III. (THE SIMPLE), the 8th king

throne of his ancestors.

**CHARLES IV. (THE FAIR)**, the last king of the direct line of the Capetian dynasty, born in 1294, died at Vincennes, Jan. 31, 1328. The 3d son of Philip IV. the Fair, he succeeded his brother, Philip V. the Tall, in 1322, visited with severe punishment the Lombard money changers for their many extortions, the judges for their prevarications, and the barons for their unlawful encroachments upon private property. He secretly aided his sister Isabelle in her revolt against her husband, King Edward II. of England, made a futile attempt to be elected emperor of Germany, and died leaving his 3d wife, Jeanne d'Evreux, pregnant. On her being delivered of a daughter, the crown went to Philip of Valois, the cousin of Charles, and the grandson of King Philip III. the Bold. The Capetian direct line ended by 3 brothers succeeding each other: Louis X., Philip V., and Charles IV.; so did the collateral branches of Valois and Bourbon.

**CHARLES V. (THE WISE)**, the 3d king of the family of Valois, son of King John II., born Jan. 21, 1367, died at Vincennes, Sept. 16, 1380. He was a prince of very little military genius, but great ability, with much taste for learning. Being

tamara against Pedro the Cruel Charles had secured for him was of great service in his and consequently instrumental in over England. Meanwhile, trade and prosperity had been restored while several important laws were founded, among the number, now the *bibliothèque de la ville*; the Bastille was also erected with a view to hold the Parisians. Charles V. was indeed, if not one of the most useful at least one of the most useful

**CHARLES VI. (THE MAD)**, the 4th king of the family of Valois, born Paris, Dec. 8, 1368, died Oct. 21, 1401. Of Charles the Wise, he was but the son; his father died; and his uncles, John, Berry, Burgundy, and Bourbon, reigned in his name. A general revolt against their oppressive rule, especially in Paris, where the *Maillotins*, from the name they were armed. Young Charles was forced by the duke of Burgundy to flee Paris, Nov. 27, 1382, the battle of 1

was violently frightened by the sudden appearance of a ragged maniac, who stopped and cried: "Do not proceed further, or you are betrayed." This overpowered already weak mind, and he fell into a derangement, which was the next day aggravated by his running the risk of being killed at a masquerade ball. Henceforth

he was prevented from attending to the duties of government; and his uncles again seized the government, the duke of Burgundy to secure his own ascendancy. The other, Duke Louis of Orleans, soon attempted to snatch the power from his hands, and opposite parties, Orleanists and Burgundians, arose to divide the court and the nation. The contest grew fiercer when John the Fearless succeeded his father, Philip the Bold, and toward his cousin of Orleans could not be ratified by causing the latter to be killed. Nov. 23, 1407. The powerful count of Armagnac, the leader of a formidable party in the south of France, at once espoused the cause of Orleans, and henceforth this faction was called by the name of Armagnacs.

The contest commenced between these and the Burgundians, and the unfortunate king was neglected and left to the care of menials; his wife, Isabella of Bavaria, whom he had married in July, 1385, gave herself up to love and political intrigues. The daughter of the emperor, Odette de Champdivers, succeeded the little queen, from having been betrothed, was almost the only one who could give any consolation to the king's distracted mind. During his lucid intervals he had sense enough to sympathize with the misfortunes of the country.

The condition of the country was becoming worse every day, when a new enemy appeared in the person of King Henry V. of England, landing on the coast of Normandy, and his victory over the French at Agincourt, Oct. 25, 1415, as complete as those of Crécy and Poitiers. France was every where given up to rage, murder, fighting, and bloodshed. For a period of 4 years, there seemed to be no negotiations were entered into; but the treacherous murder of John the Fearless, in the presence of the dauphin, Sept. 10, 1419, gave a new impetus to the war. Philip the Good, son of John the Fearless, to avenge his father's death, with the aid of his wife, Isabella, and King Henry V. of England, concluded a treaty at Troyes, May 21, 1420, in virtue of which the latter received the hand of the king's daughter Catherine, and the regency of France for the present in case of the king's death. In all these transactions the unfortunate prince had of course nothing to do; he could not sanction them by his presence or

Henry V. did not long enjoy his power. He died Aug. 31, 1422. His son, Charles, himself died shortly afterward, leaving France in the hands of the English.

CHARLES VII. (THE VICTORIOUS), the 5th

king of the house of Valois, born in Paris, Feb. 22, 1403, died at the castle of Mehun-sur-Yèvre, near Bourges, July 22, 1461. The 5th son of Charles VI. and Isabella, he became by the early death of his brothers heir apparent to the crown in 1416. In 1417 he was appointed lieutenant of the kingdom, and 2 years later he assumed the title of regent, without however being able, on account of his indolent habits, to exert any authority; he was but a tool in the hands of his favorites, most of them leaders of the Armagnac faction. On the death of Henry V. and Charles VI. in 1422, Henry VI. of England was proclaimed king of France, at St. Denis, and his authority recognized by the majority of the people, while Charles was supported only by a few citizens of central and southern France. He was so poor and powerless that his enemies called him the *roi de Bourges*, as if this city were the whole of his monarchy. The duke of Bedford, who governed in the name of Henry VI., successfully waged war against Charles, and the English troops, victorious in several encounters, concentrated themselves around Orleans, which was the stronghold of the French king. His position was utterly helpless, when suddenly a young peasant girl, Joan of Arc, the celebrated "Maid of Orleans," came to his rescue. Her enthusiasm, patriotic devotion, and confidence in victory, inspired the French troops with new ardor, while terror spread among the English. Orleans was delivered, the enemy repeatedly defeated, and the king triumphantly brought to Rheims, where he received the holy unction. From this time, Charles was indeed the real king in the eyes of the whole people, who every where rose in his behalf. The war became a national one, in which the lower classes, who had until then remained nearly indifferent, took an active part. The capture and death of the heroine, far from damping the popular enthusiasm, kindled a new spirit. The French gained considerable advantages; and finally the treaty of Arras, concluded in 1435, between the king and Philip of Burgundy, insured their ultimate triumph. Henceforth Charles appeared to be a new man; he distinguished himself by wisdom, prudence, and bravery; he achieved the task which had been commenced by others, and partly deserved the glorious appellation which has been attached to his name. Peace was reestablished, order and tranquillity prevailed, and prosperity revived throughout the kingdom. A regular army was organized from 1439 to 1448; the finance department, the administration of justice, and the other branches of the government were put on a better footing. In many of his reforms Charles was assisted by Jacques Cœur, the richest and most enterprising merchant of the time, whom he had made minister of finance. The improved condition of the country secured the sympathies, and, on the renewal of hostilities, the assistance even of those provinces which were still held by the English. Consequently, in the space of a few

his associates, who attempted to resist her, and gave for a few years to France a degree of peace and prosperity, till her brother became of age. The chivalric romances and accounts of Charlemagne's heroic deeds had imbued his rather weak mind with the idea that it was his mission to restore the Roman empire, and to take Constantinople from the Turks. At the head of a powerful army he entered Italy in 1494, triumphantly marched through the peninsula, and took possession of Naples. Satisfied with his military exploits, Charles left a part of his army in Naples, and hurried home with a select body of about 9,000 soldiers. When in the neighborhood of Parma, he met at Fornovo an army of 40,000 Italians, who sought to intercept his return; but in spite of their numbers the young king routed them and triumphantly re-entered France. He soon learned that his army had been defeated by the Spaniards under Gonzalvo de Cordova, and that Naples had returned to its old allegiance. He was planning a new expedition when he suddenly expired from the effects of an apparently trifling accident.

CHARLES IX., the 12th king of the family

denly it was reported that Adam had been shot by a man commonly known as the king's assassin. This was an accident, but it was too late for the French to take measures for their security; they were weak and defenceless. On the night of Bartholomew's day (1572), at the Louvre, the Catholic arms and mercenary slaughterers, who had confided in the king, killed him. It is difficult to determine what Charles IX. in the fatal deed had acted under the pernicious influence of Catherine de' Medici. This terrible event from him the frantic exclamation was construed as an order: "Well, all, that not a single Huguenot preach me with their death!" afterward manifested signs of remorse, and breathed his last when only 23 years of age, amid dreadful corporal and spiritual torments.

CHARLES X., the 7th and last king of the family of Bourbon, born at Versailles, 1757, died at Goritz, in Illyria, 1836, was the 4th son of the dauphin Louis XVI., and reigned at his birth

scandalous conduct was, however, somewhat restricted by the influence of the dauphiness Marie Antoinette, and his love for Mme. de Polastron. On one occasion he rashly insulted his cousin, the duchess of Bourbon, at the opera ball; and his duel with the duke, which grew out of this circumstance, seriously impaired the favor which his affable and courteous manners had gained for him. He tried to make amends by distinguishing himself at the siege of Gibraltar, but in vain; his levity and inconsistency had destroyed the last vestige of his popularity. When the revolution broke out, faithful to the traditions of his house, he became one of its most uncompromising enemies. But instead of supporting his unhappy brother, Louis XVI., he fled from Paris to Brussels, then to Turin, where he engaged in intrigues, the consequence of which was to increase the danger to which his brother was exposed. On May 20, 1791, he had an interview with the emperor Leopold at Mantua, and a few months later was present at the conference of Pilnitz, the only result of which was to give a new impetus to the revolutionary spirit in France. He continued to go about begging assistance for the royalist cause; meanwhile the king was arraigned before the convention, sentenced to death, and executed. The exiled prince, who now assumed the title of Monsieur, repaired to Russia, where Catherine II. presented him with a magnificently ornamented sword bearing this inscription: "*Donnée par Dieu pour le Roi.*" But this was a useless weapon in such weak hands. The ill-directed efforts of the Bourbons and their allies having proved fruitless on the Rhine, it was thought proper to give encouragement and assistance to the Vendéans or Chouans. Monsieur was consequently sent, Aug. 1795, with English ships, to effect a landing on the coast of Brittany. Although supported by a large number of emigrants and some 2,500 English troops, the brave Charette, who was in waiting for him, having gathered nearly 20,000 Vendéans, and engaged his word that 60,000 more would rise in arms on the arrival of a Bourbon, the prince did not dare to land, and his cowardice was the signal of the ultimate defeat of the monarchical party in western France, the heroic peasants of Brittany and Vendée being tired of giving their lives for princes by whom they were deserted. From this period to 1814, Monsieur lived in obscurity, residing mainly in England. On the fall of Napoleon, he repaired to Paris. On April 12, 1814, he was welcomed there by the provisional government, headed by Talleyrand. A part of the Parisian population hailed his return, while his affability of manners and kind words conciliated the good will of many. The most popular saying reported of him at the time was: "Friends, nothing is changed in France; there is only one Frenchman more." Notwithstanding this favorable beginning, 11 months had hardly elapsed when Monsieur was again compelled to leave France, after having vainly tried to secure the city of Lyons against

the approach of Napoleon. The last defeat of the emperor at Waterloo brought him back again to France in the train of the European armies. During the first years of the restoration, he kept aloof from public affairs. He was, however, the head of the ultra-royalist party, which so seriously interfered with the policy of Louis XVIII. That party at last prevailed by the accession of the Villèle cabinet, and the influence of Monsieur became prominent. He succeeded Louis XVIII., Sept. 16, 1824, under very favorable auspices, his brother not having been a favorite with the nation. At first he adopted some popular measures; but soon his government appeared to be ruled solely with a view to the reëstablishment of the old régime. A bill to indemnify the emigrants for their losses during the revolution was introduced; this bill, by which the nation was to assume a thousand millions of new debts, in behalf of those who had actually borne arms against it, was adopted, March 27, 1825. This was a great triumph for the reactionary party. Soon another bill was passed, decreeing the most severe penalty against what was called sacrilege. In the legislative session of 1826, an attempt was made to alter the law of inheritance, so as to reëstablish the right of primogeniture; this, however, failed. Another bill, to regulate or rather to destroy the freedom of the press, called *loi de justice et d'amour*, was not more successful. The public discontent was further increased by the favor shown by the government to the Jesuits who had reëstablished themselves in France, under the new appellation of *pères de la foi*. At last the popular sentiment broke out during a review of the national guards, held April 29, 1827, by the king himself; he was received by the cries of "Down with the ministers," "Down with Villèle." Greatly provoked by these manifestations, his haughty answer was that he "came to receive homage, not lessons." On the same night a decree of dissolution was issued against the national guards. A few weeks later, the chamber of deputies was also dissolved, while the royalist party was reëstablished in the chamber of peers by the addition of 76 new members. At the same time, the freedom of the press was entirely suppressed by the reëstablishment of the censorship. To divert public attention, the government resolved on assisting Greece in her war of independence, but the glory achieved by French arms failed to restore popularity to the cabinet; and Charles X. at last consented to part with his ministers and choose new counsellors among the most liberal royalists. The Martignac ministry, formed Jan. 4, 1828, was the signal of a kind of reconciliation between the king and the nation. The measures then adopted were hailed with delight by the friends of constitutional liberty, but created the utmost dissatisfaction among the court party. The king, fearing the ascendancy of liberal principles and following the suggestions of the ultra royalists, dismissed the Martignac administration, and in-

trusted Prince Polignac with the formation of a new cabinet. The prince was indeed the truest representative of that old royalist party which had "forgotten and learned nothing." His mere name was considered as a challenge offered by the king to the nation; every one foresaw the coming struggle. In vain the government tried to assuage public opinion by the excitement of military success. The expedition against Algiers was undertaken; that stronghold of piracy was stormed on July 6, 1830. But all to no purpose; the interest of the whole nation was engrossed by home affairs. On the opening of the chambers, March 2, the king had made use of threatening language, and to this a majority of 221 deputies answered by voting an address declaring their want of confidence in the ministry. The king declined to receive the address, on which the chambers were adjourned, and on May 16 they were dissolved. New elections took place, and resulted in a still more powerful opposition majority. Incensed at this, and encouraged by the triumph of the French army in Algeria, the king resorted to a *coup d'état*. Decrees were promulgated to suppress entirely the freedom of the press; to dissolve the newly elected, but not yet opened, chamber of deputies, and prescribe an essential modification in the mode of election, so as to secure the triumph of the court party. These ordinances fell like a thunderbolt on Paris. Resistance was immediately organized. Barricades were built, and defended by bodies of workmen from the suburbs, and by artisans and printers, under the command of officers and young men from the polytechnic school. The insurrection was emphatically popular, and not confined to any particular class. The royal troops, under Marshal Marmont, offered but unwilling resistance, and were driven from the capital in less than 3 days. Charles X. was so little conscious of the danger of his situation that he remained quietly at the palace of St. Cloud; he learned but gradually the defeat of his troops, being to the last under the impression that he had to deal only with a riot. But it was a revolution, and when he attempted to avoid its consequences it was too late. He recalled the fatal ordinances, appointed a liberal ministry, and even abdicated in favor of his grandson, the duke of Bordeaux, the present count of Chambord, but all in vain; the chiefs of the revolution would not accept such proposals; the king had no alternative but to depart. He retired first to Trianon, then to Rambouillet, under the protection of his guards. In the latter place, he made some show of resistance; but on the appearance of 10,000 volunteers from Paris, he gave it up entirely, and, accompanied by commissioners sent by the chamber of deputies, he directed his course toward Cherbourg. There, on Aug. 16, he embarked for England with his family and a few faithful servants, on board of 2 American ships, the *Great Britain* and the *Charles Carroll*. He landed at Cowes as a private individual, under the name of comte de Ponthieu. He

immediately repaired to

warriors, slaughtered all who offered resistance, devastated the towns which were not prompt enough in their submission, and now considered his power firmly established. Far from it; they rose the following year, and, notwithstanding repeated defeats, renewed their resistance in 777, but in vain. Charles's power now seemed securely established. He held a *placitum* at Paderborn, where many Saxon tribes acknowledged his power and were baptized. Their intrepid chief, the hero who inspired them with his courage and love of independence, Wittikind, had been obliged to take refuge with a northern prince. Charles improved this interval of apparent tranquillity to lead his warriors against the new caliph of Cordova, Abderrahman. Crossing the Pyrénées in 778, he took Pamplona, Saragossa, and the territory as far as the Ebro; but a severe misfortune attended his return to France. The rear-guard of his army, being overtaken in the narrow passes of Roncesvalles by the Basques, the inveterate enemies of the Franks, was destroyed to the last man; and among the valiant chiefs who were slain was Roland, whom history scarcely notices, till his later renown in the annals of chivalry. But the presence of Charles was required on the Elbe; the indomitable Saxons had revolted again under Wittikind; they could not endure the foreign yoke, and, above all, they hated the attempts made to convert them to Christianity. Charles adopted against them measures of the greatest severity and cruelty; more than 4,000 prisoners were at one time slaughtered; many thousands of the Saxons were transplanted with their families into Frankish countries; part of Saxony was laid waste, and every means resorted to to crush the spirit of its unfortunate inhabitants. Two great battles, which took place at Detmold in 788, destroyed their last forces, and Wittikind, despairing of the future, surrendered in 785, swore allegiance to Charles at Attigny-sur-Seine, and was baptized. This, however, was far from being the last of these bloody struggles; the independence of Saxony found other champions, who more obscurely, but not less heroically, undertook their patriotic task. The alternate succession of risings and defeats went on almost uninterruptedly, until Saxony, being completely exhausted by repeated losses, and bent down under the despotic organization devised by Charles, had no recourse but to give up her national freedom and religion. The diffusion of the gospel was aided by conquest; the bishoprics or missionary stations of Minden, Halberstadt, Werden, Bremen, Münster, Hildesheim, Osnabrück, and Paderborn were the origin of as many cities; and the old Saxon nationality was completely broken down. While this desperate struggle was still at its height, Charles had to baffle the treacherous designs of Tassilo, the Agilolfingian duke of Bavaria, who, although a tributary of the Frankish king, held secret intercourse with his enemies, and attempted to unite the Saxons, the Lombards, the Saracens, the Avars, and the Slavonians

against Charles. The duke was arrested, arraigned as a traitor before an assembly of lords at Ingelheim in 787, and sentence of death passed upon him, which, however, was commuted by Charles to imprisonment in the monastery of Jumièges, near Rouen. Bavaria was now divided into counties under Frankish governors. Charles afterward conquered several of the Slavic tribes along the banks of the Baltic, undertook a war of extermination against the Avars, which lasted from 794 to 799, and put their country under the administration of Frankish counts and bishops. Charles, having thus taken possession of the north-east of Spain, the larger part of Italy, and northern and eastern Germany, found himself at the beginning of the 9th century master of an empire bounded N. by the Baltic sea, the Eyder, the German ocean, and the British channel; W. by the Atlantic ocean; S. by the Ebro, the Mediterranean, and the Volturno; E. by the Save, the Theiss, and the Oder. Margraviates, or military marches, were established for the protection of the land frontiers, while fleets were in readiness on the sea-shore to oppose the piratical invasions of the Saracens and the Northmen. So extensive a dominion seemed fully to warrant a higher appellation than that of king; and moreover, the ultimate aim of Charles's conquests had been the restoration of the western Roman empire. Having been induced to visit Italy to protect Leo III. against his rebellious clergy, the Frankish king was solemnly and triumphantly crowned by the grateful pontiff in St. Peter's church, on the Christmas day of the 800th year of the Christian era. Henceforth he styled himself emperor of the West, and with a view of reestablishing the ancient Roman empire, he proposed to marry Irene, the Byzantine empress; a project baffled by the deposition of Irene. This was a great era in the middle ages; the Christian kings of Spain, the Mussulmans of Fez, and the caliph of Bagdad, Haroun al Rashid, sent ambassadors to present homages and gifts to the powerful western monarch.—However great as a warrior and the founder of an empire, Charles deserves still more praise as a lawgiver, a civilizer, and a patron of learning, science, and art. He endeavored to establish order and a regular administration among the many nations which his sword had united, most of which were in a barbarous condition, totally different in their origin, language, and manners, and hostile to each other. Great national assemblies, known as *champs de Mai*, were held yearly in the spring. (See CHAMP DE MARS.) Other assemblies took place in the autumn, but were merely councils of military and ecclesiastical lords whose advice the emperor was pleased to receive, and who, under his directions, prepared the bills and projects to be submitted to the national meeting. In addition to the laws thus adopted by the nation, Charles issued edicts known as capitularies, in which regulations for the administration of the empire as well as

the management of the emperor's private property were enacted. The collection of these capitularies, a number of which have been preserved, is among the most valuable relics of the middle ages, and affords striking evidence of rare foresight, wisdom, and prudence in their author. His empire forming, ethnologically, various kingdoms, Charles placed at their head his own sons with the title of kings, but they were nothing more than his lieutenants, the supreme power being concentrated in his own hands, he alone appointing the officers intrusted with the administration. His whole dominion was divided into a number of counties governed by earls (*Grafen*), and these were placed under the supervision of imperial delegates, or *missi dominici*, who 4 times every year visited the circuits assigned to them, holding provincial meetings and courts of justice, receiving the accounts of the collectors of public money, and adjusting the grievances of the people. Charles was thus enabled to control every branch of administration, as well as the proceedings of the various functionaries, who were appointed for a term of 8 years only. His protection extended to the clergy, increasing their wealth by a law upon tithes, their liberty by his respect for canonical elections, and their power by certain judicial prerogatives; but at the same time keeping them under his dominion, submitting them to the *missi dominici*, restricting their rights of asylum, interfering with questions of discipline and even of dogma, and causing the monasteries to be reformed by Benedict of Aniane. Trade and industry were not less objects of his fostering care; he granted privileges to merchants, and reduced as much as possible the tolls to which they were subjected. He established uniformity of currency, had the coinage executed in his palace, and regulated the value of gold and silver coin. Beggars were not permitted to prowl about the country, but were provided for by the lords or communities to which they belonged. Charles bestowed particular attention upon general instruction and the revival of classical learning. Illustrious men were invited to his court from all parts of the world, and especially from Italy, to diffuse among his subjects various branches of learning, as grammar, rhetoric, logic, arithmetic, astronomy, history, theology, and medicine. The Anglo-Saxon Alcuin, a native of York, a man of considerable information, if not thorough learning, seems to have been the leading spirit of this aggregation of teachers; he was the originator of the Palatine school, a kind of normal institution, from which men, thoroughly instructed, were sent into the provinces, and constituting at the same time an academical society, which consisted of the emperor himself, several members of his family, mostly females, and the most distinguished of his courtiers. The academicians assumed names borrowed from antiquity; Charles himself was styled David, while 2 of his daughters, Gisèle and Rothruda, were called Delia and Columba.

These ladies and some of the monks of various orders were employed in making copies of ancient manuscripts, a task, however, specially devoted to the monks of various orders. Charles gave great encouragement to the study of letters, and such copies, and especially the famous palimpsest at Aix la Chapelle. Charles, in his desire of knowledge, was conversing with the learned during his hours, and having been present at his meals. During the day he frequently got up to study the course of the sun. Through such diligent application he was much of a scholar as was consistent with his duties; and some literary works, such as a German grammar, and a collection of the national songs of Germany. The fine arts were neglected by him; he had the Greek adopted in the churches, and brought from Italy, whose concerts he patronized. Among the many palaces constructed by him, we must mention those of Ingelheim, Nimeguen, and Aix la Chapelle. The latter was a masterpiece of architecture, having been ornamented with columns and sculptural fragments brought from Italy; it was a large and magnificent building, the spacious halls and rooms of which were decorated in a splendid manner, and filled with most elegant and costly furniture. The basilica in the same city, erected also by Charles, was equally celebrated, and became the pattern of many churches built during the 9th century. He moreover encouraged civil engineering; a wooden bridge, 500 paces long, was constructed at Mainz over the Rhine; and a gigantic canal was commenced, but not completed, to establish through this river and the Danube a water communication between the German ocean and the Black sea. As a man, Charles, according to Eginhard, was of a tall and commanding figure; either standing or sitting, he had an air of grandeur and dignity; and notwithstanding the shortness of his neck and his obesity, he was well proportioned and remarkably active, with a firm step and manly appearance, his shrill voice alone being not in accordance with his person. A perfect adept in the use of weapons, he was also an unrivalled swimmer and a consummate hunter. Although encouraging magnificence of attire among his courtiers, he was generally plainly dressed, giving preference to the old Frankish style of costume. He was frugal and temperate, and evinced great severity against drunkards. He had 9 more or less legitimate wives, by whom he had at least 20 children. The only son who survived him was his successor, Louis le Débonnaire. Several among his many daughters led a dissolute life and caused great scandal, which their father and afterward their brother were unable to suppress. The awe with which Charles inspired his contemporaries increased as time rolled on; his historical deeds, amplified and adorned by poetry, powerfully seized upon the popular imagination; and

the great emperor and his 12 legendary peers became the heroes of innumerable chivalric romances, which were recited or sung everywhere, and the collection of which is now called the "Carlovingian Cycle." His name also won a halo of sanctity, the anti-pope Calixtus II. having canonized him in 1165, and Pope Gregory XI. having ordered his anniversary to be celebrated on Jan. 28. The origin of many of the learned institutions has been ascribed to him; and fiction and truth are so much blended in his history that it is difficult to distinguish the one from the other. But, however this may be, Charlemagne takes his rank among those extraordinary men who, from time to time, appear to change the face of the world and inaugurate a new era in the destinies of mankind.—The literary works attributed to Charlemagne are: 1, his "Capitularies" (first collected by Ansegise, abbot of St. Wandrille, best edition that of Étienne Baluze, Paris, 1677, 2 vols. folio); 2, "Letters" contained in the collection of De Bouquet; 3, a "Grammar," of which fragments are to be found in the *Polygraphia* of Trithemius; 4, his "Testament," contained in Bouchel's *Bibliothèque du droit François*, tom. iii., printed at Paris, 1667, folio; 5, some Latin poems, such as the "Epitaph of Pope Adrian," and the "Song of Roland;" 6, the Caroline books.—The cathedral of Aix la Chapelle stands on the site where Charlemagne had erected a chapel, which he designed as his burial-place. The chapel was destroyed by the Normans, and rebuilt in its present form by Otho III. toward the close of the 10th century. The position of the tomb, in which once reposed the remains of Charlemagne, is marked by a slab of marble under the centre of the dome, inscribed with the words *Carolo Magno*. When the vault was opened, the body of Charlemagne was found seated on his throne, clothed in the imperial robes. These relics are now deposited in Vienna, excepting the throne, which alone remains in the cathedral of Aix la Chapelle. Among the books which treat of Charlemagne we may refer to the great biography of his contemporary, Eginhard, *Vita Caroli Magni*, in Duchesne's *Rerum Francorum Scriptores* (the best edition is that by Pertz, in the *Monumenta Germaniæ Historica*, 2 vols., also by Ideler, Hamburg, 1839, 2 vols.; an excellent German translation appeared in Berlin in 1850); Monachus Sagallensis, *De Gestis Caroli Magni*, libri ii.; Donatus Acciaiolus, *De Vita Caroli Magni Commentariis*; Leclerc de la Bruère, *Histoire du règne de Charlemagne*; B. Hauréau, *Charlemagne et sa cour*; Struve's *Rerum Germanicarum Scriptores*, tom. i.; Dippold's *Leben Kaiser Karl's des Grossen* (Tübingen, 1810); Gaillard's *Histoire de Charlemagne* (2d edition, Paris, 1819, 4 vols.); Lorenz, *Karl's des Grossen Privat- und Hofleben*, in Raumer's *Historisches Taschenbuch* (1832); Capefigue's *Charlemagne* (2 vols. Paris, 1840); Sporschil's *Karl der Grosse* (Darmstadt, 1845). Dr. F. Piper has recently edited from the original MS. *Karl des*

*Grossen Kalendarium und Ostertafel* (Berlin, 1858). Among the more popular works upon this monarch may be mentioned the "History of Charlemagne," by G. P. R. James (1832).

CHARLES THE FAT, or *le Gros*, the last emperor of the Carlovingian dynasty, born about 832, died in 888. He was the 8d son of Louis the Germanic, and received the kingdom of Swabia for his portion of his father's possessions. After the death of his oldest brother, Carloman of Bavaria, he succeeded him in the imperial dignity and in the possession of Italy (881), and after that of his younger brother, Louis of Saxony (Jan. 20, 882), he became king of all Germany. On the death of Carloman of France in 884, Charles the Fat united France under his sceptre with Germany and Italy, and the vast empire of Charlemagne was thus again vested in one and the same sovereign. He proved, however, utterly unworthy of this exalted position. "Charles the Fat upon the throne of Charles the Great," says a German historian, "was a caricature of weakness and contempt; this master of nations, harassed, humiliated by every foreign and internal enemy, a passive tool in the hand of his minister, an inactive spectator of the sufferings of his people, was covered with domestic as well as public disgrace." His incapacity and cowardice soon became manifest. The city of Paris being besieged by the Northmen, he marched against them with a large army from Germany; but instead of fighting the enemy, he offered them large sums of money and the pillage of Burgundy to obtain their retreat. This shameful conduct raised general indignation; the Bavarians, Saxons, Thuringians, and finally the Alemanni, deserted him and deposed him solemnly in an assembly at Trebur in 887. He had already been disowned by the French. He died the next year, poor and forsaken, in a cloister near Constance. He was noted for his inordinate love of the pleasures of the table, and this as well as his natural corpulency gave him the surname of "the Fat."

CHARLES IV., emperor of Germany, the son of John, king of Bohemia, who fell in the last battle of Crécy, born in Prague, May 18, 1316, died Nov. 29, 1378. Several years before the death of Louis of Bavaria, the emperor being under excommunication of the pope, the king of Bohemia had been chosen in his stead. But Louis, partly by the great superiority of his talents, partly by the support given to him by the princes of the empire, who were especially jealous of the papal power, and had within 10 years adopted at the diet of Rense the most energetic measures against the claims of the holy see, easily conquered the blind Bohemian, who threw himself thenceforth almost entirely into the hands of the pope and of the French king. He was of the family of Luxemburg, and so allied to the royal house of France; and consequently he caused his son, who was a man of some considerable ability, though of a cold, politica,

fawning, and treacherous disposition, to be educated in that kingdom, and to be brought up as much as possible a Frenchman. So far as his interests led him in that direction, Charles of Luxemburg, as he was called, was willing to be German, French, or for that matter, English. Nevertheless, he had not the slightest idea of sacrificing his own life or that of his people in behalf of a king who would never adequately reward his services. Therefore, so soon as he saw that the English archery had in fact won the day, and that the English king was pressing the broken troops of France so hard as showed that there would be no second battle, by which to redeem a victory already lost, Charles of Luxemburg took himself off the field, and left his gallant father and a handful of brave countrymen to die, the former because he would not outlive his honor, the latter because they would not survive their king. By this event, Charles succeeded to the throne of Bohemia, and having been chosen emperor by 5 electors (July 19, 1346), hoped to succeed without opposition, when Louis died, a little more than a year afterward. The electors of Brandenburg and the Palatinate, the archbishop of Mentz, and the duke of Saxe-Lauenburg, assembled at Lahnstein, declared the choice which had fallen upon Charles IV. void, and proceeded to elect in his place Edward III. of England, the conqueror of Crécy, and brother-in-law of the late emperor. But the English parliament obliged him to decline the proffered dignity. Equally fruitless was their election of Frederic the Severe, landgrave of Meissen, who likewise refused the crown. Twice disappointed, they now elected Günther von Schwarzburg, a knight distinguished by his feats of arms, in whose favor they gained over the Poles, those ancient enemies of the house of Luxemburg; and for a time the prospects of Charles seemed to be at the lowest. He set himself, however, to accomplish by underhand intrigue the same ends in secret which the failure of the Hohenstauffen, of his grandfather Henry, and of Louis of Bavaria, clearly proved to him the impossibility of effecting by open violence. He was the first of the emperors who introduced that foreign policy against which his predecessors on the throne had so manfully but unsuccessfully striven. The Hapsburgs had made some weak attempts of a similar nature, but it was not until this reign that modern policy took deep root in Germany. He empoisoned German policy with every hypocritical art, by the practice of courtly treachery and secret murder, in which he had become an adept in France. Primogeniture, first introduced by him into his family, passed into that of the Hapsburgs, and at all events promoted the dismemberment of the empire, whose external power was thereby increased, notwithstanding the moral paralysis of its effect. He craftily entered at this juncture into negotiation with Edward, to whom he proved the necessity of an alliance between them against France; drew

the Hapsburg army on his side by giving his daughter Catharine in marriage to Basil, the son of Albert the Lame; and with equal skill dissolved the Wittelsbach confederacy by wedding Anna, the daughter of the count palatine Rupert, by ceding Brandenburg to Louis the Elder, and declaring Waldemar, whom he had himself invested with the electorate, as his postor. Louis the Elder, with equal pathos, sacrificed Günther, who was shortly afterward, in 1347, poisoned by one of the emissaries of Charles. Those who surrounded the deathbed of Günther in his last moments extorted from him an abdication, for which they were sufficiently paid by Charles. He now stood at the head of the house of Luxemburg. He dissolved the alliance between the pope and France, and prevailed upon the pope to quit Avignon, and to cast himself again upon the protection of the German empire. His view with regard to Italy did not extend to restoring it to the empire, but only to procuring the ceremony of his coronation at Rome. Flattering also in this, he visited Rome in a private capacity; took no heed of the Italian factions, except to foment discords between them; betrayed Rienzi, who trusted himself confidently in his power, and sent him in chains to the pope; flattered Petrarch, who implored him, as Dante had previously implored Henry VII., to restore Italy to the empire, with fair and fine words; and, in a word, by his conduct so disgusted the Ghibellines, who had hoped by his means to strengthen their party, that they set fire to the house which he inhabited at Rome, and he narrowly escaped with his life. At Rome he was received with the greatest distinction by the papal legate, and on the day after the coronation (1355) withdrew from the city, in obedience to secret orders received from the pope, in order to avoid being proclaimed temporal sovereign. Ten years later, his policy was completely rewarded by his success in detaching Pope Urban V., the successor of Clement, from the French alliance. Two years later, again, when that prelate returned home, he was visited by Charles, whom he met at Viterbo, and to whom he vouchsafed the honor of conducting him to St. Peter's, leading the horse he rode by the bridle as he walked at his side. Next he applied himself to the reorganization of the empire, by getting the whole constitution of the electoral college into the power of himself and of the future emperors *de facto*; and this he in a great measure accomplished by the promulgation of the celebrated golden bull at the diet of Nuremberg in 1356, which continued to be a fundamental law of Germany until the dissolution of the empire. This was the most important achievement of his reign. At a later day, the corruptions and feuds which he had encouraged broke out on all sides throughout the empire; the league of the cities was at war with the nobles; the country was devastated by bands of robbers, and all seemed on the verge

but it was not his policy, base and as that had been, which created the ces, but the general ferment of the mind of the people, which was here, but especially in Germany, to seethe and boil with new ideas cal and ecclesiastical reform, and ould not be settled until after many a urbulence, commotion, and war. By nacy he raised not only the power of family but that of the empire, and eeded by intrigue and cunning where enstauffen with all their valor and nity had failed. His domestic and policy was, it must be admitted, eral, and beneficial. He bestowed s of laws, in the main just and ad-as, on Bohemia, Moravia, and Silesia. rred privileges on the aristocracy he cities, encouraged agriculture and promoted internal navigation, intro-man artificers into Bohemia, converted of that country into a smiling garden, l the capital with fine public edifices ly buildings, patronized learning and rts, founded universities, and generally the progress of education and the g of his people. Altogether, he was anomaly. As a man, and especially as n, he must be pronounced odious; yet he is not without claims to considera-ven to respect. "Charles," says Men- account of his reign is singularly discriminating, "was named—falsely, l more for the empire than any em- ce the Hohenstauffen—the stepfather ipire, but the father of Bohemia. His iscovered his Bohemian descent, his ace to his mother being stronger than her. He was diminutive in stature, -set, carried his head ill and drooping had high cheek bones and coal-black s Slavic appearance curiously con-ith his sumptuous attire, for he seldom the imperial crown and mantle, and h manners and education. He spoke ges, and was deeply versed in all the of his time. Part of his biography y himself is still extant. He also drew lan for the new part of the cities of ad Breslau." He bequeathed the king-Bohemia and Silesia to his eldest son, us; to Sigismund, the 2d, the electo-randenbourg; and to the 3d, Lusatia. e works referring to Charles IV. may oned Pelzel's *Geschichte Kaiser Karl's* ue, 1780-'82), and Dönnige's *Geschichte chen Kaiserthums im 14 Jahrhundert* (841).

LES V., emperor of Germany, and Spain under the title of Charles I., hent, Feb. 24, 1500, died at the mo-f Yuste, near Plasencia in Estrema-in, Sept. 21, 1558. He was son of Burgundy, archduke of Austria, and he daughter of Ferdinand and Isabella

of Spain. His father was son of the emperor Maximilian, and the beautiful Mary, daughter of Charles the Bold and Isabella of Bourbon. By the death of his father Philip, he became in 1506, when only 6 years old, heir presumptive to the entire possessions of the house of Hapsburg in Germany, in right of his paternal grandfather, Maximilian, and to the splendid sovereignty, or dukedom, as it was called, of Burgundy, afterward the Spanish Netherlands, in right of his paternal grandmother, Mary. By the death of Ferdinand the Catholic, his maternal grandfather, in 1516, he inherited the kingdom of Spain, now one and undivided, the kingdom of Naples, and all the boundless empire of Spain in America, beyond the western ocean. It was his boast that the sun never set on his dominions; he bore 2 globes on his escutcheon, and on his coin 2 pillars, those of Hercules, the boundaries of the old world, with the motto *Plus ultra*, or "more beyond." He was, on his arrival at the age of manhood, the mightiest, the wealthiest, in every respect the most powerful prince in the world. In extent of territories, in number and quality of populations, whence to draw unlimited supplies of the best soldiers in Europe, in revenues, and treasures of gold and silver, in maritime resources and abilities, no one could so much as aspire to compete with him. He was educated in the Netherlands, under the care of William Oroy, lord of Chièvres, who had him thoroughly instructed in military exercises, in history, and in those business habits which are essential to the conduct of affairs of state; he brought him up stern, cold, regular in his life, grave, formal, and dignified in his manners; but he made him solely and entirely a German, and this was a disadvantage to him in his after life, as he never gained the sympathies of his Spanish subjects. From the moment of his accession to the throne of Spain, Charles had set his ambition on the imperial crown, which had been so long the property of his grandfather Maximilian, but he had at the same time the ability to perceive, that to pretend to the succession at this time would be to array against himself the jealousy of all the other potentates of Europe, and the prudence to avoid a premature disclosure of his object. His motto was *nondum* (not yet), but he nevertheless awaited his time only, and made the surer of his object by his seeming neglect of it. In the mean time, Martin Luther had shaken the church to its base. On the death of Maximilian, Frederic of Saxony, the friend and protector of the bold reformer, became regent of the empire. When the imperial election came on, Francis I. of France, who was the most dangerous competitor of Charles, was rejected on the ground of his not being a German, though it was believed at the time that his partisans were induced by golden arguments to desert his cause. Henry VIII. had, it appears, for a short time, entertained a hope of attaining the imperial dignity; but so soon as he was assured that he was too late in the field, he directed the whole weight of his in-

fluence to be thrown into the scale in favor of the Spanish monarch. Charles was eventually elected emperor, June 28, 1519, and taking leave of his Spanish subjects, whom he disliked, and with whom he was not popular, proceeded to Worms, where a great diet was convoked of all the estates and princes of the empire, to receive the emperor, regulate the affairs of the empire, and decide the Lutheran controversy. The last was really the great and determining question of the day. But Charles lacked the foresight to discover its paramount importance. In view of the pretensions of his rival Francis, and his military preparations against Italy, it appeared to the emperor to be of all things the most essential to preserve the unity of the German empire, free from dissension. The efforts of Charles were necessarily directed by the course of events to the repression of the attempts of Francis I. against Italy; and he had need of all his power and ability to effect that end, and to prevent or frustrate the constant and formidable coalitions which were made against him, so often as he appeared to be gaining any decisive advantage over his impetuous and impulsive rival. Thus, after the tremendous battle of Pavia, in which, by the consummate generalship of Charles of Bourbon, the arms of the empire triumphed over those of France, while Francis himself was made prisoner on the field, he was reduced to the necessity of making peace and releasing his captive on conditions, to the observance of which the latter swore on the Gospels previous to his liberation, but which, so soon as he was free, he repudiated, by the union of the pope, the king of England, the French, the Venetians, and all the Italian princes. A second time, when the French again invaded Italy and were again defeated, near Pavia, the emperor again consented to a peace, which is known as the "ladies' peace," having been negotiated by the mother of Francis and the aunt of Charles, Margaret, the princess regent of the Netherlands. Shortly after this reconciliation, the war of the peasants and the nobility being suppressed, and the moderate councils and doctrines of Luther continuing to prevail, the Catholic princes entered into a closer league of interest with the emperor at the diet of Spire, and endeavored to prevent the further progress of the new doctrines by a decree that the church should remain *in statu quo* until the convocation of a council. This step led to the celebrated protest of the Lutheran princes, whence the name of Protestants, April 19, 1529. The necessity of concentrating his forces against the Turks, who were besieging Vienna and had laid waste all the country as far as Ratisbon, added to the admitted impossibility of crushing the Lutheran party, except by open recourse to arms, led Charles, in accordance with the views of the pope, to limit his efforts to the promotion of dissensions among the princes. But on the retreat of the Turks, the subject was again taken up at Augsburg, when a religious war appeared inevit-

able, until a new incident, who thought to place himself in the western, as he already held the eastern empire, produced of strife. Scarce had the emperor been by a temporary and internal dissensions and commenced. Zwingli was killed, his party suffered a total defeat, the doctrines of Luther were followed, the convocations of towns after the dissolution of the empire, Denmark, and the persecution of the Netherlands, and the ultimate suppression in Münster of Trent, the death of Luther, and sulting from the confederation of princes, followed in quick succession. France being humbled in new wars, a certain degree gained over, pacified by the cession of part of the pope and the emperor turned to the suppression of the heresy. All ineffectual. The warfare was continued on the Protestant side chiefly by Albert von Culmbach. At length, a furious battle took place between Maurice and Albert, the latter under the ban of the empire, a depredator, opposed to all in arms, brought the war to a while, by means of a treaty concluded at Augsburg in 1555, the false peace of Augsburg. Charles determined to fulfil his long cherished wish of abdicating his numerous crowns in succession to his son Philip, who was also have resigned the empire had the education of that prince, and his bigoted character, increased his aversion as unconquerable as he regarded them. At a splendid assembly in a splendid assembly, he surmounted and authority in the empire, and in the succeeding years, according to the chief of the crowns of Spain, with all the depending on them, both in the new world, was accomplished. He retired soon to the monastery of Yuste, in the remaining years of his life. Diocletian had there been an imperial abdication, and religious solitude, a favorite theme of Roman writers, had been imitated by authors prior to the recent discovery of the letters of the emperor, in which it is proved that, in profound and pious

never more intently occupied with the course of contemporary affairs; that instead of attaining to generosity of sentiment or loftiness of thought, he increased only in severity and intolerance, and bitterly regretted that he should have allowed the escape of Luther; and that instead of triumphing over an appetite which had always been ungovernable, he shocked his physician by the immense supplies of partridges, capons, sirups, pies, sausages, omelettes, and flagons of wine, which were constantly ordered for his table. Politics and gastronomy were the subjects of almost every letter which proceeded from the imperial hermitage. Though he had a passion for horology, there is no evidence, according to Mr. Prescott, that he ever made the philosophical reflection concerning the absurdity of attempting to produce uniformity of faith among men, since he could not make any two of his timepieces agree. He suffered severely from the gout, and, among other eccentricities, is said to have had his own funeral obsequies performed in the chapel of the monastery a short time before he was attacked by the malignant fever which caused his death. Menzel has summed up his character in the following sentences, which may be deemed impartial, although perhaps not enough allowance is made for honest religious scruples, from which it is hardly just to assume that Charles was wholly free, and for natural predilections in favor of the faith in which he had been brought up: "Charles, although dexterous in the conduct of petty intrigues, was entirely devoid of depth of intellect, and even misunderstood his age; magnanimous in some few instances, he was unendowed with the greatness of character that had empowered Charlemagne to govern and to guide his times. Possessed of far greater power than that magnificent emperor, the half of the globe his by inheritance, he might, during the 30 years of his reign, have moulded the great reformation to his will; notwithstanding which, he left at his death both the church and the state in far more wretched disorder than at his accession to the throne of Germany. Frederic II. was too dull of intellect to rule a world; Charles V. was too cunning. He overlooked great natural advantages, and buried himself in petty intrigue. Luther remarked of him, during his youth: 'He will never succeed, for he has openly rejected truth, and Germany will be implicated in his want of success.' Time proved the truth of this opinion. The insufficiency of the reformation was mainly due to this emperor. Ferdinand I., opposed in his hereditary provinces by a predominating Protestant party, which he was compelled to tolerate, was politically overbalanced by his nephew Philip II. in Spain and Italy, where Catholicism flourished. The preponderance of the Spanish over the Austrian branch of the house of Hapsburg exercised the most pernicious influence on the whole of Germany, by securing to the Catholics a support which rendered reconciliation impossible; to

the Spaniards and Italians, admittance into Germany; and by falsifying the German language, dress, and manners. The religious disputes and petty egotism of several estates of the empire had utterly stifled every sentiment of patriotism, and not a dissentient voice was raised against the will of Charles V., which bestowed the Netherlands, one of the finest provinces of Germany, upon Spain, the division and consequent weakening of the powerful house of Hapsburg being regarded by the princes with delight." By his wife Isabella, daughter of King Emanuel of Portugal, he had one son, the future Philip II. of Spain, and 2 daughters. He was succeeded as emperor by his brother Ferdinand I.—Among the works treating specially of Charles V. the most important are Antonio de Vera's *Vida y hechos de Carlos V.*; Prudencio de Sandoval's *Historia de la vida y hechos del emperador Carlos V.*; Robertson's "History of the Reign of the Emperor Charles V." (London, 1769; German translation by Mittelstedt with comments by Remer, Brunswick, 1795); Lanz's *Correspondenz des Kaisers Karl V.* (Leipzig, 1844-'46); and Charles's instructions to his son Philip II., translated into French by Teissier (the Hague, 1700). The MS. of a description of the capture of Tunis, in the handwriting of Charles, dated Tunis, July 23, 1585, and addressed by him to his sister Mary, regent of the Netherlands, has been discovered by M. Gachard, keeper of the Belgian archives. For the life of Charles V. after his retirement, the best original authorities are MSS. in the archives of Simancas. Upon these are chiefly founded the Gonzalez MS.; the *Chronique de Charles Quint*, by Pichot, Paris, 1854; the *Retraite et mort de Charles Quint*, by Gachard; Mignet's *Charles Quint*, &c.; Stirling's "Cloister Life of the Emperor Charles V.," and Prescott's appendix to the Boston edition of Robertson's history of the reign (Boston, 1856).

CHARLES VI., 2d son of the emperor Leopold I. of Germany, and Margaretta Theresa of Spain, born Oct. 1, 1685, died Oct. 20, 1740. He was educated from his childhood with a view to the Spanish throne, to which, on the death of Charles II., the last Spanish king of the house of Hapsburg, he was entitled. But Charles II., dying without heirs male, in defiance of the Austrian right, left his throne by will to Philip, duke of Anjou, second grandson of Louis XIV. of France; and on the death of the Spanish monarch, in 1700, Philip took possession of the kingdom. A war ensued, in which most European powers took part, and which is known as that of the Spanish succession. In 1708 Charles was proclaimed king of Spain, in Vienna, under the name of Charles III. With the assistance of England and Holland he eventually, June 26, 1706, was proclaimed king also in Madrid, but obstinately declined being crowned, because he had not the regal outfit which he thought requisite to support his dignity. This proved fatal to Charles. The French having had time to receive reinforcements, and

obtain an abler general, in the person of the duke of Berwick, natural son of James II., and nephew on his mother's side of the great English captain, defeated the allies in the battle of Almanza, which recovered for Philip the whole of Valencia, and ultimately restored to him the crown, which he had once lost had his enemy taken the occasion to assume it. In 1708 and 1709, the war languished in Spain, Charles being shut up in Barcelona, which was gallantly defended by a small garrison of 2,000 men, until it was relieved by an English fleet; but the great successes of the allies in the Netherlands inclined the French, exhausted by continual reverses, to sue for peace. Spain would have been abandoned, even, had not the German cabinets insisted on the expulsion of Philip by the arms of his own uncle, Louis XIV. In consequence of this, the war continued. In 1710, the allies in Spain being reënforced, the Germans and the English gained a signal victory at Saragossa; Philip was again driven from Madrid, and Charles, when it was too late, entered it, amid the mournful and ominous silence of the people, who had been taught to regard him as the tool of the English heretics, and were excited against him by the influence of the pope, the clergy, and the Jesuits. France sent powerful reënforcements, and her best general, Vendôme, and the English commander Stanhope suffering himself to be surprised and made prisoner at Brihuega, Charles was once more shut up in Barcelona, to which thenceforth his kingdom was limited. Joseph I., emperor of Germany, dying without issue in 1711, Charles, at the suggestion of Eugene, was elected emperor, and recalled to Germany, where he was crowned at Frankfort-on-the-Main in December of the same year, and one year later king of Hungary, at Presburg. His wife, Elizabeth of Wolfenbüttel, and Count Stahrenberg, remained two years longer in Barcelona, in a fruitless attempt to retain the kingdom; but they were forced to withdraw, and Catalonia fell a prey to a cruel vengeance. In England the tories came into power, who had always sided with France, on account of the support it gave the Stuarts, whom they still hoped to see restored. Marlborough was replaced by Ormond, who was secretly ordered to retreat, abandoning the Dutch under Albemarle to defeat, and obliging Eugene to retire from his position at Quesnoy. This was followed by the peace of Utrecht, concluded in 1713, between France and England, by which England retained Gibraltar, Minorca, and St. Christopher's, obtained the demolition of the fortress of Dunkirk, and the right of free trade with the Spanish colonies, in consequence of which she guaranteed to Philip the possession of the throne of Spain. Holland shortly afterward acceded to the peace. The German empire, though abandoned by England and Holland, could still have compelled France to listen to reason, had it been possible for her various governments to act in concert. Eugene was forced

to negotiate with Villars; but so insistent was the French in their demands, that the prince left Rastadt, where the conferences were held, on his own responsibility, and Louis XIV. yielded, fearful that persistence might awaken even Germany from her stupor. The treaty of Utrecht was recognized. Philip retained Spain, England Gibraltar. Charles VI. retained all the Spanish possessions in Italy, Naples, Milan, Sardinia, the Netherlands, and the fortresses of Kehl, Freiburg, and Breisach, and the territory west of the Rhine which had formerly belonged to France, for which that power received Ladau in exchange. In the following year, Sardinia was given by Austria to the duke of Savoy, in exchange for Sicily, and that prince took the title of king of Sardinia. Charles VI., being the last heir male of the house of Hapsburg, gave his whole attention to preserve the inheritance of all the crowns which he held in his daughter Maria Theresa of Austria, whom he had given to Francis of Lorraine; an end which he hoped to attain by what is known in history as the pragmatic sanction, a compact or guarantee, procured at immense cost, of all the nations. Spain's consent was purchased by the cession of Tuscany, Parma, and Piacenza; France was conciliated by the promise of Lorraine; England and Holland by the abolition of the commercial society of Ostend; and Augustus of Saxony and Poland, by the assurance of the succession of the crown of Poland to his son Augustus III. The latter assurance speedily involved Europe in a fresh war. On the death of Augustus II., the Poles proceeded to hold a reëlection, for which Stanislas Leszcynski again offered himself as a candidate, and, although he was not much favored by the nobility of Poland, Charles held steadily to his engagement. The exertion of his influence, united to the active intervention of Anne of Courland, the niece of Peter the Great, who had governed Russia since 1730, and who had already mooted to the emperor and to Prussia the scheme for the partition of Poland, secured the crown to Augustus. Anne sent Marshal Münnich, at the head of 40,000 Russians, into Poland, expelled Maurice the Strong (Marshal Saxe) from Courland, of which he had been elected duke, and conferred that dignity on her partner Biron, whom she had elevated from the lowest position, he being in fact only the son of an ostler. Stanislas was forced to fly from his dominion, and in consequence France, Spain, and Sardinia declared war, not on Augustus or on Russia, but on the empire, evidently with no object but that of plundering that power. The Russians sent 20,000 men to assist the emperor; England and Holland remained neutral; and Prince Eugene, owing to the death of his able antagonist, the marshal duke of Berwick, was enabled to maintain himself on the Rhine. Every where else, however, the imperialists suffered severe losses. Villars gained a great victory near Parma, in which Mercy, the imperial general, was

tain; and although his successor Königsberg surprised the allied camp on the Secchia, capturing 500 guns, the fate of the campaign went against the empire, while Don Carlos of Spain succeeded in making himself master of the kingdom of Naples. These successes were not, however, turned to the advantage of France to the extent that might have been expected. Louis XV., steeped in licentious dissipation, cared little for conquest or glory, so long as he could enjoy undisturbed the pleasures of his harem, and a truce was concluded, by which the former stipulations of the emperor were accepted. Don Carlos retained Naples; Parma and Tuscany were given to Lorraine, the sovereignty of which was bestowed on Stanislas Leszczyński, 1736, with the reversion to France on his death, which occurred in 1760, when Lorraine became French. During the remainder of his reign, the emperor was constantly engaged in wars with the Turks, from whom he vainly fancied he should be enabled to make conquests, which might counterbalance his losses in the west of Europe. But on the death of Prince Eugene, the army which he had created fell into a state of total demoralization. The house of Hapsburg became extinct in the direct line by the death of Charles, which happened while he was busily employed in reorganizing the financial system of his empire, which was in a terribly distracted condition, and in arranging the last details of the pragmatic sanction by procuring the election of his son-in-law, the duke of Tuscany, husband of the beautiful and high-spirited Maria Theresa, as king of the Romans. After his death, the pragmatic sanction immediately dissolved itself, as by common consent of all parties, not one of the contracting powers abiding by the guarantees which Charles had purchased at so dear a rate; and it was only by the courage and abilities of his daughter that the hereditary possessions of the house of Hapsburg were preserved and transmitted without dismemberment.

CHARLES VII. (KARL ALBRECHT), emperor of Germany, born in Brussels, Aug. 6, 1697, died in Munich, Jan. 20, 1745. His father was Maximilian Emanuel, elector of Bavaria, and governor of the Spanish Netherlands. Joseph I., having taken possession of the elector's possessions in Bavaria, outlawed him, and detained his son as prisoner at Klagenfurth and Göriz, where the young prince, however, enjoyed every advantage of education. Liberated in 1714, after the conclusion of the treaty of peace of Rastadt, Charles Albert was sent as commander of the troops against Turkey in 1716-'18. In 1722 he married a daughter of Joseph I., having previously renounced all rights arising from this marriage to the empire of Austria, and adhered to the pragmatic sanction. Four years afterward he succeeded his father as elector of Bavaria. His first act now was to protest against the pragmatic sanction, and after the death of Charles VI. in 1740, he put forth his claims to the Austrian succession, which had already

been urged by his father, immediately on the accession of Maria Theresa. In order to insure his claims, he concluded at Nymphenburg an alliance with France and Spain, May 18, 1741. With the assistance of French troops he captured Linz, where he was proclaimed archduke of Austria, and afterward took possession of Prague. Elected king of Bohemia, and soon afterward German emperor, he proceeded to Frankfort-on-the-Main, where, Feb. 21, 1742, he was crowned emperor of Germany by his brother, the elector of Cologne. The Hungarians, however, rose in favor of Maria Theresa, whose army occupied Munich, reconquered upper Austria and Bohemia, and compelled Charles to resort to flight. The efforts of his general, Seckendorf, enabled him to return to Munich, April 19, 1743; but in June he was again expelled by the victories of Maria Theresa's troops. About the same time his allies, the French, were defeated near Dettingen by the English allies of the Austrian empress, and Charles would never have regained possession of his capital but for his alliance with Frederic of Prussia (May 22, 1744), who invaded Bohemia, and for the exploits of Seckendorf. But prostrated by adversity, he died soon after his reëntrance into Munich. He was a weak man, wholly incapable of the part which he aspired to play.

#### IV. NAPLES.

CHARLES D'ANJOU, king of Naples and Sicily, count of Anjou and Provence, born about 1220, died in 1285. He was the youngest brother of Louis IX. of France, and married Beatrix, the heiress of Provence, thus becoming related to Henry III. of England and Richard of Cornwall, the king elect of Germany, who had married the 2 eldest sisters of Beatrix. He accompanied his brother in his first crusade, landing with him in Egypt in 1249, and being taken with him a prisoner by the Saracens. On his liberation he came back to Provence, where he had first to reëstablish his authority in some of the large cities. He greatly assisted his mother, Blanche of Castile, in her regency during the king's absence in Palestine. On the death of the emperor Conrad IV. the kingdom of the Two Sicilies was offered to him by Pope Urban IV., in defiance of the rights of the Hohenstauffen. Crowned at Rome, he marched against Manfred, the natural brother of Conrad IV., who had been proclaimed king by the Sicilians. At Grandella, near Benevento, he won a great battle in 1266. Here his rival was slain, and he assumed at once over the reluctant Italians a power which he maintained by unmitigated severity. The numerous adherents of the Hohenstauffen, aware of the popular feeling, invited young Conradin, son of Conrad, to Italy. This brave prince, then scarcely 16 years old, entered his hereditary states, where he was enthusiastically received. Every thing seemed to promise him victory; his army was numerous and full of confidence; but the crafty Charles, with forces comparatively small, succeeded in defeating his young oppo-

ment in 1268, at the battle of Tagliacozzo, and making him his prisoner. He subsequently had him executed on the principal square of Naples, after going through the mockery of a trial. The friends and adherents of the prince were also unmercifully dealt with, and the unpopularity of the conqueror was still further increased by the insolence of his French soldiery. In 1270 Charles sailed for Tunis, to join his brother Louis IX. in his 2d crusade. On his arrival he found Louis dead; he succeeded, however, in compelling the bey of Tunis to acknowledge himself his tributary. On his return he planned the conquest of the eastern empire, but his schemes were baffled by the insurrection commonly called the "Sicilian vespers." This dreadful event, which had been brought about by Charles's tyranny, took place March 30, 1282. Sicily placed itself under the protection of Don Pedro of Aragon, and Charles tried in vain to reconquer the island. He was overpowered by the superior cunning of Pedro and the prowess of the admiral Roger dell' Oria. During this hard contest, it was proposed that a duel should take place at Bordeaux between the 2 princes, a proposal eagerly accepted by Charles, although he was already 60 years old; but the offer was only made by Pedro to gain time, and the Aragonese did not appear on the appointed day. Charles repaired in haste to Italy, hoping to take revenge on the battlefield; but on arriving at Gaëta, he learned that his son had been defeated and taken prisoner in a naval engagement with the Aragonese admiral. This misfortune preyed heavily upon his mind; the inflexible warrior now became as wavering as he had been resolute. His death soon followed. He was succeeded by his son, Charles II., called the Lamb, who began to reign in 1289, after his liberation from prison. He also tried in vain to reconquer Sicily. He died in 1309.

## V. SARDINIA.

CHARLES ALBERT (CARLO ALBERTO AMADEO), king of Sardinia, born Oct. 2, 1798, died at Oporto, July 28, 1849. The son of Charles Emanuel of Savoy-Carignan, of a younger branch of the royal family, and having consequently no hope of ever obtaining the crown except by the extinction of the direct line, he early adopted liberal principles, and was even affiliated with the carbonari. Being appointed regent, March 18, 1821, on the abdication of King Victor Emanuel, he did not hesitate to proclaim in Sardinia the constitution adopted by the cortes of Spain and to appoint a provisional junta; but his plans were immediately baffled by the marching of an Austrian army into Piedmont, and the rejection by King Charles Felix of all his measures. He then withdrew from Turin, resigned his office, and left the kingdom. In 1823, he served as a volunteer in the French army which, under the duke of Angoulême, invaded Spain, to crush the liberal party; he was consequently charged with perfidy by his old friends. In 1824, he was allowed to

return to Turin, and the post of viceroy. On the death of Charles, elder branch, succeeded to which, however realizing the anti freedom. So system was a to agricultu criminal laws were army received an which greatly increased measures were mingled to national liberty. king was as undecided as cession of Pope Pius IX. to return heartily to his a constitution to Sardinia; he amnestied the exiles of liberty to the pr revolution of 18 champion of It aided with and the ducies of P dena, saying boldly help him in the as ("Italy will be cessfully at first, trengo, April 30, 1 June 11; and sto chiera; but ill he was in his 25, by Marshal Radecenza, Treviso, and retreat to and from risk of being taken, istice, through which vantages. On the resumed hostilities; Ohrzanowski, was vara, March 23, 1844, had placed in him were resigned the crown to his Emanuel II., and retired to died 4 months later. I back to Turin, where in his honor.

CHARLES EMANUEL I., surnamed the Great, duke of Savoy, born at the castle of Nivoli, Jan. 12, 1562, died at Savillon July 26, 1630. He succeeded his father, Philibert Emmanuel, surnamed Ironhead, in 1580. His bold and enterprising spirit, instigated by boundless and unscrupulous ambition, soon embroiled him in the wars of his time, and he successively entered into alliances with Spain, France, and the emperor of Germany, which he broke, however, as soon as it suited his interests. But he was possessed of remarkable talent, even of great scientific accomplishments, and distinguished himself by his courage in many a battle. In 1585 he married Catherine, the daughter of Philip II. of Spain. This connection, and some pretensions to the throne of France after the death of Henry III., made him the enemy of

IV., who had still to conquer his country. In war with Henry for the marquisate of Saluzzo, and with the Swiss cantons of Valais and Bern, he was compelled by a defeat at St. Joire (Oct. 1589) to an unprofitable peace, but soon recommenced hostilities in league with the Catholic league, penetrated Provence, occupied Barcelonnette, Antibes, Gréjus, and entered Aix as victor (Nov. 1601). This was but the commencement of a war, which was carried on with varied success after a series of victories and defeats terminated by the peace of Lyons (1601), which gave Saluzzo to Charles Emanuel in exchange for some small frontier districts ceded to France. He then made a sudden attack on Valais, but the enterprise failed; many of his men were killed, others hanged as robbers. In view of the growing influence of Spain in Italy, he entered into alliance with France and England; but after the assassination of Henry IV. (1610), France concluded peace with Spain, leaving the duke of Savoy. He then broke the alliance of the house of Hapsburg, after the extinction of the ducal line of Mantua, laid claims to Montferrat (1612). At the death of the emperor Matthias (1619), he came a candidate for the crown of Germany, but was beaten by Ferdinand II. Restless in his ambition (which also led him into schemes of conquest in Cyprus and Macedon), he attacked Genoa (1624), and finally brought himself the enmity of all his former allies. The French occupied Pignerol, threatened Savoy, and finally conquered it. Broken by these disasters, the old Charles Emanuel died suddenly. He was a zealous patron of letters and sciences, but plunged his country into wars by his ambitious wars. He was succeeded by Amadeus I.

## VI. SPAIN.

CHARLES IV., king of Spain, born in Naples, 12, 1748, died in Rome, Jan. 19, 1819. The son of Charles III., he succeeded to the throne in 1788, having married at an early age his cousin, Maria Luisa of Parma, by whom he was entirely controlled. When Manuel Godoy, a handsome man in the body guards, became her lover, contrived to make him the friend of her husband; and she succeeded so well, that they together on the most intimate terms, the favorite of the queen becoming also the favorite of the king. He was always ready to con-  
 sider favors upon Godoy; raised him very early to the rank of a lieutenant-general, and bestowed upon him the title of duke of Alcudia and the office of minister of foreign affairs. Complications arose with the French republic, and to the efforts of Charles to save the life of his cousin, Louis XVI., whose execution he retarded by declaring war against France. His army, however, was soon worsted, and he was obliged to conclude in 1795 a treaty of peace with France. This treaty was signed by Godoy, who then assumed the title of "Prince of the

Peace." In consequence of this alliance with France, Charles became involved in a war with Portugal and England. The hostilities against the former country did not last long, nor were they severe; but in the contest with the latter, the Spanish navy received a deadly blow, in 1805, at the battle of Trafalgar, while Spain lost, at the same time, its richest colonies in America. Napoleon, who found a pliant tool in Godoy, finally resolved on deposing Charles IV., who also had an enemy in his own son Ferdinand. The young prince, whose bad qualities were still unknown to the nation, gained universal favor by his opposition to Godoy and the French rule, and used his influence to annoy his father. Charles, disgusted with his son's conduct, and tired of the French domination, resolved to retire to Spanish America; but on the very day he intended leaving his royal residence at Aranjuez, March 18, 1808, he was stopped by a tumult of the populace instigated by Ferdinand. The rage of the people was now directed against the queen and Godoy. In order to save Godoy's life, Charles abdicated in favor of Ferdinand, but a few days later sought to withdraw the abdication. Napoleon put an end to the feud between father and son by deposing them both. Charles and Ferdinand were taken to Bayonne, where Napoleon was to pronounce between them as an umpire. As soon as the emperor got them in his power, he obliged Ferdinand to restore the crown to his father, who was in his turn persuaded to relinquish it to Napoleon. This episode was the turning point of the all-powerful emperor's fortune. As for Charles, he received in exchange for his crown the castle of Compiègne, surrounded by a forest abounding in game, with a yearly pension of 6,000,000 francs. Notwithstanding the allurements of Compiègne, Charles went to Marseilles. In 1811 he was permitted to repair to Rome, always in company with his wife and Godoy, who, strange to say, became every day dearer to him. After the fall of Napoleon, Ferdinand having given dissatisfaction to the Spaniards, a proposition was made to Charles to renew his claims to the crown; but he refused, his only desire being to spend his latter years in retirement in the company of his wife and of her paramour. The former having died in Dec. 1818, grief preyed so much upon his mind that he died within a month afterward.

## VII. SWEDEN.

CHARLES XII., king of Sweden, born in Stockholm, June 17, 1682, killed at the siege of the fortress of Frederickshald, Norway, Nov. 30, 1718. He was the eldest son of Charles XI. (born Nov. 24, 1655, died April 15, 1697), a peaceful and wise prince, who improved the internal condition of his kingdom, opened the succession to females, and left the crown, with a full treasury, to his son. Charles was well educated by his father, learning French, and speaking fluently in Latin and German, beside his native tongue; he was more than an

having obtained by the treaty of the Hague the aid of England and Holland, assumed the initiative with great energy. In May, 1700, he embarked at Carlsrona for the island of Zealand, designing to attack Copenhagen with a fleet of 80 ships of the line, beside transports, assisted by a Dutch and English squadron. In his first engagement Charles gave evidence of the impetuous and daring courage for which he was afterward distinguished; for, on nearing the place of disembarkation, he leaped into the sea, and was the first man on the enemy's soil. Copenhagen was bombarded by the fleets, and would have been invested and closely besieged, when further operations were terminated by negotiations, which had for their result the signing of a separate peace at Travendahl (Aug. 8, 1700), Frederic IV. of Denmark deserting the coalition, and resigning Schleswig-Holstein to the house of Gottorp. In the mean time, a Polish army had overrun Swedish Livonia, and laid siege to Riga, while Peter of Russia besieged Narva, at the head of semi-barbarous hordes, who were only driven to the assault by the terror of the knout. The sword which Charles now drew was never again to be

a hollow way, where he must ally retreat, he merely bowed a word, turned his horse's head by the way he had come. A brought against him under the Riese, whose effeminacy rendered subject of scorn to the gallant F for Charles was everywhere Clinsow, July 30, 1702, he victory, which would have had not Charles been detained by Oracow, which delayed the cause that although he was closely followed by the Swedes under Rehnska, tinnally escaped, and afterward owing to the invasion of Finland, which required the war Charles until 1705. Charles in petty struggles with Poland, allowing the young and growing north to recuperate itself at he might have crushed the enemy in the end crushed himself. However, his thoughts seem to fixed on placing another king Poland, young Sobieski having

ck upon Russia, and Charles, dashing rap-  
 across Silesia into Saxony, was there re-  
 with an enthusiasm of zealous joy, second  
 that which had formerly welcomed the  
 of Protestantism, Gustavus Adolphus.  
 old step so terrified Augustus that he  
 his 2 principal councillors from Poland,  
 full powers to treat with Charles; but  
 the treaty had actually been signed, hav-  
 en compelled during the progress of ne-  
 ons, which were secretly carried on, to  
 his Russian ally at Kalisz, where Peter  
 ctorious, he was so much elated, that he  
 ed the report that peace had been con-  
 between himself and Charles false in  
 particular. The declaration did nothing,  
 er, to eject that prince from Saxony, of  
 he kept absolute possession, and in  
 Augustus was held in utter contempt  
 testation in consequence of his tyranny, but  
 ore of his apostasy from the Protestant  
 . The Saxon was soon compelled to  
 his pretensions, and to meet Charles in  
 ence at Altranstädt, where peace was de-  
 ely concluded. By it Augustus resigned  
 ims to the throne of Poland, and had the  
 to surrender to the conqueror the per-  
 f young Sobieski and the unhappy Patkul,  
 t whom the vengeance of Charles was  
 ilarly excited. He had already put to  
 General Patkul, who was in the Saxon  
 a, and had defended Warsaw against his  
 as being born a Livonian, and therefore  
 dish subject; and he now committed a  
 which is the deepest blot on his escutcheon,  
 wing himself to be carried away by his  
 for his Livonian *quasi* subject, and  
 g Patkul to die the agonizing death in-  
 only on the lowest and most degraded  
 ctors, of being broken on the wheel.  
 after the signing of the peace the events  
 residence of Charles in Saxony are very  
 kable, as he fixed his headquarters at  
 städt, and acted in all respects as if he  
 the sovereign of the country, recruiting  
 mies from its subjects, and compelling  
 hat place by threat of arms the emperor  
 istria, who had dispossessed his Pro-  
 t subjects of 125 churches, which had  
 given up to the Jesuits, to restore those  
 had been confiscated, and to permit the  
 on of 6 new ones. The emperor was at  
 me hard beset by his enemies. At this  
 re, had Sweden joined the coalition against  
 mpire, it would have been in peril of  
 ruin; and, in order to avert this calamity,  
 ough was sent to visit the Swedish con-  
 . The courtly talents of the handsome  
 olished Englishman were not exerted in  
 Charles was persuaded to withhold his  
 om the coalition, and to turn the weight  
 arms and military genius against Russia.  
 pt. 1707, the Swedish monarch invaded  
 ountry at the head of 48,000, marching al-  
 y the very route in which Napoleon follow-  
 th above 12 times the number of troops, a

little more than a century later, and shared al-  
 most identically the same fate, and in as nearly as  
 possible the same manner, except that the line  
 of his operations having been diverted to the  
 southward, it was into the Turkish territory, not  
 into his own country; that he effected his escape.  
 He crossed the Beresina at Borissov, stormed  
 the Russian lines at Holowczyn, wading the  
 river Wabis, in which he sunk up to the neck,  
 at the head of his forlorn hope, and was at one  
 time surrounded by the Calmucks, many of  
 whom he slew with his own hand. Thence he  
 pursued the enemy with such inconsiderate  
 haste and rashness, that he lost himself and his  
 army amid the forests and morasses of those  
 dreary solitudes. His artillery was lost in the  
 swamps, his men died of hunger, while he was  
 yet advancing; yet he still pressed resolutely  
 onward, the enemy wasting the country before  
 him, according to the invariable practice of the  
 people. Gen. Lewenhaupt, who was attempt-  
 ing to join him with reënforcements from  
 Sweden, was waylaid and defeated, after a des-  
 perate conflict which lasted during 8 entire  
 days, by the czar in person, at Liesna, notwith-  
 standing which he succeeded in joining his  
 master at the head of 6,000 men. Up to this  
 time it had been the plan of Charles to strike  
 direct at Moscow; but when he reached Smo-  
 lensk he was persuaded by Mazeppa, the hetman  
 of the Cossacks, to turn his line of march toward  
 the Ukraine, where the hordes were not as yet  
 reconciled to the Russian yoke, and where they  
 had promised to aid him. But Peter laid waste  
 the country, constantly retreating before him  
 and refusing to deliver battle, and Mazeppa, who  
 was proscribed, failed to aid him until he forced  
 his way, with fearful loss of life from cold,  
 hunger, and fatigue, in the depth of the winter  
 1708-'9, as far as to Gadatch upon the Dnieper  
 in lat. 52°, where he retired into winter quar-  
 ters with the intention of attacking Pultowa, a  
 strong town on the river Vorakia, with an  
 abundance of all provisions and supplies of  
 which his army was in want, in the com-  
 mencement of spring. Before that time arrived,  
 however, his forces were so fearfully reduced  
 that Peter, who, since his defeat at Narva, had  
 completely reorganized his army, resolved to  
 fight, and appeared at the head of 70,000 men,  
 at the moment when his invader was about to  
 invest the city. It so happened that while recon-  
 noitring the advance of the enemy Charles was  
 dangerously wounded in the thigh, and was  
 obliged to limit his exertions, on the day of  
 battle, July 8, 1709, to issuing his commands from  
 a litter instead of directing their manœuvres  
 himself, and charging in person at their head.  
 It is said that there were, moreover, disagree-  
 ments between Rehnköld and Lewenhaupt,  
 and that the Swedes, who were preëminently  
 a manœuvring army, did not display their usual  
 superiority in tactics on this occasion. All  
 advantages, however, without counting this,  
 were in favor of the enemy: vast superiority  
 of numbers, better equipment, perfect condition

of men and animals, a superb artillery, above all a single leader, and he their czar. There was reason enough why the Russian should win the day, and he did so completely. Charles escaped, with extreme difficulty, with a handful of followers, into Turkish territory, old Mazzeppa adhering faithfully to his fallen fortunes. The last salvo was fired by Prince Maximilian Emanuel of Würtemberg, who commanded a Swedish regiment. He was taken prisoner and treated with extreme distinction by the czar. The Swedish division of Lewenhaupt was overtaken and compelled to surrender on the Dnieper, and Charles, escaping to Bender on the Dniester, a strong fortress which was then in Turkish territory, where he was hospitably received and allowed to fix his residence by the Ottoman Porte, employed the whole power and energy of his mind to bring about a war between Turkey and Russia. This he succeeded in doing, and the grand vizier, taking the field at the head of 200,000 men, shut Peter up in the Crimea, and his affairs seemed utterly ruined; when his mistress, for she had not yet become his wife, Martha, afterward Catharine I. of Russia, bribed the grand vizier with all her jewels to allow the Russians to escape. That day was decisive of the fall of Charles and of the rise of Russia. Charles, who had been greatly aggrieved that to him had not been assigned the chief command of the Turkish army, galloped impatiently into the camp, but too late to prevent the escape of the czar. Frustrated as he was and severely mortified, the king of Sweden still continued year after year, until 1713, to linger at Bender, incessantly employed in endeavoring to awaken the Turkish government to a consciousness of the danger of allowing the Russians to consolidate their rising power, and constantly hoping that he had succeeded, but ever hoping in vain. He effected the overthrow, by the intrigues of the agents whom he employed at Constantinople, of 4 successive grand viziers, and felt justified in his long delay by the reasonable hopes he entertained of placing himself at the head of a powerful Turkish army. In the mean time Livonia and Esthonia fell a prey to Russia, immediately after the calamity of Pultowa. Riga surrendered. Courland became the property of Peter, who caused its duke to marry his niece Anne Petrovna, and then designedly and deliberately drank him to death. Pomerania was next invaded. The Saxons seized the whole of Poland on the flight of Stanislas, who, deserted by all his adherents, joined Charles in Turkey; the allied forces of Saxony and Russia made themselves masters of all Swedish Pomerania, with the exception of Stralsund and Wismar; and after the war had been carried on with the most atrocious cruelty, Stade, Altona, Garz, and Wolgast being burned to the ground in the dead of winter, and nearly all their inhabitants perishing of hunger, cold, and misery, Prussia was induced to join the anti-Swedish league by the promise of the future possession of Stettin.

But, about this time, strange events took place in Turkey, which nearly altered the whole state of affairs in Europe. The Russian agents having at length persuaded the Ottoman Pera that the residence of Charles at Bender was dangerous to their safety, as he was plotting, they said, to attack Turkey from Poland should he succeed in establishing Stanislas on the throne, he received intimation that he must leave Bender; and on his positively refusing to do so, orders were issued to the seraskier of that place to bring him, dead or alive, to Adrianople. Still with characteristic obstinacy refusing to submit, he barricaded his house, and with the 200 or 300 men who composed his personal retinue, defended it against several thousand Turks with artillery, until the roof taking fire, he was forced to sally out, killing many Turks with his own hand, when his spurs at length becoming entangled, he fell and was mastered and made prisoner (Feb. 1, 1713), with his eyebrows and eyelashes burnt off his face, and his clothes covered with blood. Thence he was removed to Demotika, near Adrianople, where, obstinate as ever, he remained 10 months in bed, feigning sickness, until, becoming satisfied that he could expect to obtain nothing from the Porte, he sent off a parting embassy to Constantinople, in order to conceal his intentions, and then taking horse, in disguise, by night, travelled day and night through Hungary, Austria, Bavaria, the Palatinate, Westphalia, and Mecklenburg, in order to avoid the Saxons and Prussians, and passing through Cassel incognito, although his 2d sister, Ulrica Elenora, had recently been married to Frederic, hereditary prince of Hesse, reached Stralsund during a dark November night (Nov. 23, 1714). The moment it was known that Charles was in the city, it was invested by a combined army of Danes, Saxons, Russians, and Prussians. It was defended by Charles with extraordinary skill and talent for nearly a year; but being desperate of receiving aid from without, he was forced to abandon it, Dec. 15, 1715, when he retired to Land in Scania, where he set himself to defend his coasts. For the remainder of his reign the war was carried on for the most part by sea, and generally to the prejudice of the Swedes, though not without Charles at times making dangerous efforts against Norway. At this time his principal friend and adviser was Baron Görtz, the minister of Holstein, who undertook the cause of Charles with extraordinary energy and ability, and had all but succeeded in breaking up the anti-Swedish league, which had just been joined by George I. of England. It was the policy of Görtz to gain over Peter the Great, by any concession which might be needful, by his aid or connivance to conquer Norway, and thence, with the preconcerted aid of a Jacobite rising, to land in Scotland, and dethrone George I. in favor of the pretender. A treaty had been agreed upon, by which Peter should retain his conquests on the gulf of Finland, Stanislas

should be replaced on the throne of Poland, and Charles should be married to Anne Petrovna, the widow of the duke of Courland. Accident dissolved the whole scheme. A Swedish despatch fell into the hands of the Danes. Denmark dreaded the union of Russia and Sweden; Saxony saw that she should lose Poland; Hanover, that her projects upon Bremen and Verden, Russia that hers on Stettin would fail. Frederic of Hesse would no longer be heir to the crown of Sweden; while the power of Charles, by so great a marriage, would swell to a height dangerous to the aspirations of the Swedish aristocracy. A small Swedish force under Armfeldt had perished from cold while crossing the mountains which separate Norway from Sweden, and another, commanded by Charles in person, was besieging the fortress of Fredericks-hald, in the south of Norway, when the king was shot through the head. His death was supposed to have been predetermined by conspirators, but the hand which did the deed was never discovered. In his pocket were found a miniature of Gustavus Adolphus and a prayer book. His tomb is in the chapel opposite to that where the remains of Gustavus Adolphus are interred, in the royal mausoleum in the Ridderholms church in Stockholm. The walls are decorated with trophies of his various battles, including a standard taken with his own hands in Poland. The hat, clothes, and sword worn by him at the time of his death are preserved in the chapel. Ulrica Elenora and her husband Frederic of Hesse succeeded him on the throne of Sweden. Görtz, for his endeavors to preserve the integrity of the kingdom, was sentenced to the block. Sweden was as fatally dismembered, in order to secure the succession of a false heir to her crown, as she could have been by the utmost spite of her enemies. She has never again risen above the condition of a second rate power.—Charles was distinguished for love of justice, for intrepidity, firmness, temperance, and austerity of life. But his firmness frequently degenerated into obstinacy, his temperance into eccentricity, and his austerity into excessive severity. He was tall and of noble appearance, had a fine open forehead, large blue eyes, flaxen hair, fair complexion, a handsome nose, a pleasant smile, but little beard. Among the works which refer to his life may be mentioned that written by his chaplain Norberg, entitled *Konung Carls XII. historia*; Adlerfeld's *Histoire militaire de Charles XII.*; Lundblad's *Konung Carls XII. historia* (Stockholm, 1830; German translation, Hamburg, 1835-'40); and Voltaire's celebrated *Histoire de Charles XII.*

CHARLES XIII., born Oct. 7, 1748, died Feb. 5, 1818. He was the 2d son of King Adolphus Frederic and Louisa Ulrica, sister of Frederic the Great of Prussia. Destined from his birth to fill the high office of lord high admiral of Sweden, he received a naval education, and made several cruises in his youth. In 1765 he became president of the society of

sciences at Upsal, and in 1770 commenced the tour of Europe. On the death of his father, and the accession of his brother, Gustavus III., to the throne of Sweden, he was recalled home, where he played a very important part in the revolution of 1772, by which the power of the kingdom was vested in the person of the king, with the consent of the estates. This was effected mainly by the establishment of the order of Vasa, and by the organization of clubs and committees among the young officers of the army and navy in the confidence of the king. It was agreed that the brothers of the king should superintend and commence the movement in the country, while the king himself should attend to the management of the affair in the capital. The revolution broke out by the pretended siege of Christianstadt, Aug. 12, 1772, by Prince Charles, in which no one was injured, and the whole business was so admirably managed, that without the spilling of a single drop of blood the country was delivered from the factious tyranny of the nobles, and the king honorably restored to the authority of his ancestors. Shortly after these events, Prince Charles was created duke of Sudermannland, and appointed governor-general of Stockholm; but in the war which shortly afterward broke out against Russia, which persisted in fomenting dissensions in Sweden, he returned to his old profession, assumed the command of the Swedish fleets, and defeated the Russians in a great naval engagement in the gulf of Finland; in reward for which distinguished service he was raised to the governorship. On the murder of his brother, Gustavus III., he was appointed regent in 1792; in which situation, at a highly critical period, he preserved the kingdom for his nephew, Gustavus IV., in its constitutional form, kept it externally and internally at peace, and united for the protection of navigation in the northern seas with his neighbors the Danes. In 1796 he resigned his power to his nephew Gustavus, who, having attained his majority, ascended the throne in that year, under the title of Gustavus Adolphus IV. After his nephew's accession, Prince Charles retired into private life, passing his time in literary and scientific pursuits, and appeared no more in public affairs until his nephew having become a religious fanatic, and that of a most mischievous description, a revolution broke out in 1809, by which he was deposed and his uncle placed at the head of affairs, first as administrator of the realm, and afterward (June 20, 1809) as king of Sweden; in which title he reigned well, moderately, and wisely. His reign was cast in stormy times, during the splendid avatar and headlong fall of Napoleon; but he conducted the affairs of state with such consummate ability and prudence, that while almost every other European kingdom was in some degree a sufferer by the ill of the long protracted warfare, Sweden not only had no losses to mourn, either on the field or in the doings of cabinets, but actually re-

ceived Norway at the restoration of peace as a compensation for her loss of Finland. Charles XIII. had married, so long ago as 1774, Hedwig Elizabeth Charlotte, princess of Holstein-Gottorp, but having no heir by her, he had adopted Prince Christian of Holstein-Sonderburg-Augustenburg as his successor; and on his dying prematurely, chose Marshal Bernadotte to succeed him.

CHARLES XIV. JOHN. See BERNADOTTE.

CHARLES, archduke and generalissimo of Austria, duke of Teschen, 3d son of the emperor Leopold II., younger brother of Francis I., and uncle of Ferdinand I., emperors of Austria, born Sept. 5, 1771, in Florence, then the residence of his father as grand duke of Tuscany, died April 30, 1847. Of weak constitution and sickly, he seemed to promise little, but was soon attracted by military subjects, and became fond of geometry and other serious studies. He was 20 years of age at the time of the first war of the emperor, his brother, against France (1792). Under Hohenlohe he took part in the battle of Jemmapes against Dumouriez, and then commanded the van of the prince of Coburg, when he distinguished himself in the engagements of Aldenhoven and Neerwinden, in which the French were defeated. Belgium having been reconquered, he was appointed its governor-general, March 25, 1793. In 1794 he had a part of the Austrian command, in the battles of Landrecy, Tournay, Courtray, and Fleurus, against the victorious army of Pichegru. When the Netherlands were lost, he retired for some time to Vienna to restore his impaired health. In 1796 he took the field again as field-marshal of the empire, and commander-in-chief of the Austrian army on the Rhine, and his victories over Jourdan, at Neumarkt, Teining, and Amberg, soon compelled Moreau, who had advanced as far as Munich, to undertake his famous retreat; the French were driven over the Rhine, and only maintained in their possession the bridges of Hünningen and Kehl. Both these positions Charles attacked and took in the following winter. But while things were going on successfully in Germany under his command, the French, under Bonaparte, were everywhere victorious in Italy, and were rapidly advancing toward the heart of Austria; and when Charles was sent there to check their progress, the victorious young general, imitating the words of Cæsar, could say: "Hitherto I have had to combat armies without a commander; now I have to combat a commander without an army." Charles was compelled to conclude the preliminary treaty of Leoben, April 18, 1797, which was soon followed by the peace of Campo Formio. Having lived for some time in Bohemia, as governor of that kingdom, he was again called to arms after the violent breaking off of the congress of Rastadt (1799), and again defeated the French under Jourdan, who had crossed the Rhine, in the battles of Ostrach and Stockach. Dissensions between him and the commanders of the

allied Russian troops checked his successful operations, and after the defeat of Korsakoff by Masséna at Zürich, he had again to guard the Rhine. Bad health compelled him in March, 1800, to resign his command to Kray, and to retire to Bohemia. He was not yet restored when he had to hasten again to the defence of the empire of his brother, which, by the admirable marches of Napoleon over the Alps, and of Moreau through Germany, was brought to the brink of ruin. The armistice of Steyr concluded by him with the latter was the preliminary of the peace of Lunéville (1801). His great services were now recognized by his appointment as president of the aulic council of war at Vienna, as well as by a proposition made at the diet of the German empire to reward him with a statue, and the title of saviour of Germany; which honors, however, he refused to accept. In 1805 he commanded the Austrian army in Italy against Masséna, but his victory at Caldiero (Oct. 30) was of little avail as Napoleon, after the surrender of Ulm, was rapidly advancing toward Vienna. The hasty retreat of the archduke Ferdinand to Bohemia and the battle of Austerlitz, compelled Francis to the peace of Presburg (Dec. 25). Charles was now made generalissimo of all the Austrian armies, and minister of war, with unlimited power, which he used for the reorganization of the forces of the empire, and the creation of a strong reserve and militia. In 1808, after the abdication of Charles IV., king of Spain, the provinces of Catalonia and Aragon called him to the throne of Spain and India, and an English frigate was sent to carry him from Trieste, but was sent back with his thanks. In the war of 1809 he commanded in Bavaria, while his brothers John and Ferdinand led the armies in Italy and Poland; he advanced as far as Ratisbon, but Napoleon's victories at Thann (April 19), Abensberg (20), Landshut (21), Eckmühl (22), and Ratisbon (23), compelled him to retreat. Having, however, received new reinforcements, he defeated Napoleon, who had taken Vienna, in the battle of Aspern and Essling (May 21, 22), thus shaking the belief in the invincibility of the modern Cæsar. This victory brought little more than glory; the great battle of Wagram (July 5, 6) decided against Charles, though commenced victoriously by the Austrians. He retreated in the best order and continued fighting to Znaim. An armistice, however, and soon after the peace of Schönbrunn, put an end to the bloody campaign. Charles was wounded, and feeling at the same time personally mortified, he laid down his military command, July 30, resigning all his offices, and retired to Teschen, whence he afterward went to Vienna. After the return of Napoleon from Elba, he again served for a short time as governor of Mentz; but this was the last act of his public life. He married in 1815 Henrietta, princess of Nassau-Weilburg, and became the father of a numerous and prosperous family, among whom he lived in quiet retirement.

ing the honors and distinctions due to his merits as a military commander, and a reputation for modesty, frankness, and accomplishments. His 2 works, "Principles of Chemistry," illustrated by the History of the Campaign of 1796 in Germany" (8 vols. Vienna, 1797), and "History of the Campaign of 1799 in Germany and Switzerland" (2 vols. Vienna, 1800), are highly esteemed in military literature.—Of his sons, the eldest, Albert, born 1801, is military and civil governor of Hungary; Charles Ferdinand, born 1818, and William, born 1827, are lieutenant field-marshal of Austria.—Frederic, who distinguished himself in a naval expedition to Syria (1840), died at Paris, 1846. His daughter Theresa, born 1805, was married (1837) to Ferdinand II., king of Naples; her sister, Maria Carolina, born 1825, to the archduke Rainer Ferdinand.

**CHARLES, JACQUES ALEXANDRE CÉSAR**, a French physicist, born at Beaugency, Nov. 12, 1787, died in Paris, April 7, 1823. He was remarkable for his skill in public experiments and demonstrations, and his lecture-room, in which he popularized the electrical discovery of Franklin, was attended by one of the most brilliant assemblies of Paris. Montgolfier having sent him a balloon filled with rarified air, Charles immediately constructed the first balloon ever capable of holding hydrogen gas, with which an aeronaut successfully ascended, Aug. 18, 1803. Charles afterward made an aërostatic voyage himself, rising to the height of 7,000 ft. He invented the megascope and other ingenious optical instruments, was a member of the academy of sciences and librarian of the institute, and had one of the most beautiful cabinets in France.

**CHARLES AUGUSTUS**, grand duke of Saxe-Weimar-Eisenach, son of the duke Ernest Augustus Constantine and Anne Amalia, princess of Brunswick, born Sept. 3, 1757, died Oct. 14, 1828. Having lost his father in the first year of his life, he was educated with the greatest care together with his posthumous brother, Ernest Ferdinand Constantine, under the rearing of his young mother, who, in the first year after the death of her husband, was herself still under the guardianship of her father. Upon the recommendation of Frederic the Great she appointed as their governor the count of Görtz, a former Prussian minister, giving them as teachers Seidler and Herrmann, Wieland and Herder, while Schmid conducted the affairs of the state through the difficulties of the 7 years' war. In Dec. 1774, Charles Augustus with his brother entered upon a journey to France and Switzerland, during which he made the acquaintance of Goethe, who became his friend, and afterward his minister. He had been declared reigning duke by his father on his 18th birthday, he married Louisa, princess of Hesse-Darmstadt, and continued the liberal and reformatory government of his father, gathering around him at Weimar a circle of distinguished men, among whom were Goethe,

Herder, Wieland, Schiller, Voigt, and Musæus. In 1786 he took service in the Prussian army, was in the campaigns of 1792-'93, on the Rhine, as volunteer, was made Prussian lieutenant-general in 1797, and remained in service till after the battle of Jena (1806), when he retired to his dukedom and soon joined the Rhenish confederacy. His soldiers now fought for Napoleon (who came over from Erfurt to see him, together with the emperor Alexander) in Tyrol, Spain, and Russia. Having gone over to the coalition in 1813, he entered the Russian service in the following year, and led an army of Saxons, Hessians, and Russians into the Netherlands. He then went to Paris, London, and Vienna, and took part in the campaign of 1815. The congress of Vienna rewarded him by enlarging his state, and erecting it into a grand duchy, as well as with the compensation of 800,000 thalers. He was the first of the German princes to introduce the promised constitutional representation (1816), and allowed freedom to the press, until he was induced to adopt restrictive measures by the complications that followed the great gathering at the Wartburg in 1817. He died of apoplexy at Graditz, near Torgau, on his return from Berlin. Several scientific and agricultural institutions, a park and botanical garden, are among the improvements with which he adorned his country. He was succeeded by his son, Charles Frederic.

**CHARLES CITY**, a S. E. county of Va., bounded on the S. by James river, and on the N. and E. by the Chickahominy; area 184 sq. m.; pop. in 1850, 5,200, of whom 2,764 were slaves. It was one of the 8 original shires into which Virginia was divided in 1634. Presidents Harrison and Tyler were both born within the limits of this county. In 1850 the productions amounted to 178,940 bushels of Indian corn, 81,229 of wheat, 2,461 of potatoes, and 5,144 pounds of wool. There were 6 corn and 6 saw mills, 1 tannery, 13 churches, and 92 pupils attending public schools. Value of real estate in 1850, \$861,579; in 1856, \$1,008,497; showing an increase of 16 per cent. Capital, Charles City Court-house.

**CHARLES DE BLOIS**, or **DE CHÂTELLON**, duke of Brittany, died in 1364. He was the nephew of Philip VI. of France, who, anxious to secure his fortune, married him to Jeanne de Penthièvre, heiress apparent to the ducal crown of Brittany. But on the death of John III., in 1341, the claim of Jeanne was disputed by John of Montfort, brother of the deceased, who asserted that Brittany could not revert to female sovereigns. Thence arose a war of 20 years' duration, in which the kings of England and of France participated, the former giving assistance to Montfort, while the latter supported Charles de Blois. His cause at first promised to be successful; his competitor died about 1345; whereupon Jeanne of Montfort came boldly forward in behalf of her young son, and displayed such courage, inspired her followers with such enthusiasm, and obtained such assistance from

the chivalry of England, that fortune at last declared for her. Charles was killed in 1364, and the duchy of Brittany was awarded to young Montfort.

CHARLES EDWARD, LOUIS PHILIP CASIMIR, son of James Stuart and Clementina Sobieski, and grandson of James II., king of England, born in Rome, Dec. 31, 1720, died there Jan. 30, 1788. His mother's protracted labor of 6 days might have been thought to indicate that his career was destined to afford no exception to the misery that seems to have been the inheritance of the princes of the house of Stuart. But the Jacobite party saw in his birth an event that gave them new hopes. The incapacity of the pretender, or chevalier de St. George, as exhibited in 1715-'16, and the failure of Albe-roni's plan for his restoration in 1719, had well nigh driven them to despair. The birth of Charles Edward, and the high character of the race to which his mother belonged, caused a reaction in their feelings, and prolonged the struggle between the constitutionalists and the divine right party for another generation, which was marked by desperate intrigue, and was concluded in wholesale slaughter. They were not disappointed. Charles early gave indications of talent, and of a firmness of purpose inherited from his mother, which misfortune caused to degenerate into sheer obstinacy. He was well educated by Protestant tutors, acquiring accurate knowledge of English, French, and Italian, and of the history of England. His physical education was attended to, and he was dexterous in all manly exercises. He had some taste for the fine arts, and skill in music. In his 14th year he made his first campaign, serving in the Spanish army that besieged Gaëta, in the war between Spain and Austria. Though so young, he bore himself bravely. In 1737 he made the tour of Italy, and, to the annoyance of the British government, was everywhere well received. At Venice the honors due to a crowned head were accorded to him, for which the Venetian ambassador was dismissed from England. His character at this time was that of an amiable, accomplished youth, and his sweetness of disposition is frequently mentioned. From a very early period his mind dwelt upon the thought of recovering the British throne; but if Walpole had continued to rule in England, or if his peace policy had been pursued by his successors, it is obvious that Charles must have reached middle life without an opportunity to make his cast for a crown or a coffin. It was necessary that England and France should be at war to give the chevalier a chance to regain the throne his ancestors had so unworthily filled. England and France became involved in that war which grew out of the Austrian succession, and Charles was invited to France to take command of an army that was to be sent to England. He reached that country the middle of Jan. 1744, landing not far from the place where Napoleon landed in 1815. He went to Paris, but Louis XV.

would not see him. He made a favorable impression on all persons with whom he came in contact, and particularly upon Marshal Saxe, who was to have been the real head of the invading army. That army was assembled on the channel coast, and consisted of 15,000 men. The transports were to be convoyed by 20 ships of the line and 5 frigates. The English were greatly alarmed, and the more so that war had not been declared, though it existed in fact. Their channel fleet was small, most of their ships being in the Mediterranean, where they had been sent to the assistance of the house of Austria. The prince and the marshal embarked, their preparations having been completed, at the close of February. This was the most favorable turn that the fortunes of the Stuarts ever took after the flight of James II. There was much discontent in England, they had a powerful party in Scotland, and the Irish Catholics looked upon them as promised deliverers. Marshal Saxe was the ablest of living soldiers, and one of the few generals who have beaten English armies on pitched fields. Charles was enthusiastic and resolute, and had he landed success would probably have been his. But on March 6 a great storm arose and raged for a week. Many vessels, filled with troops, were lost, and the rest were forced back to France. Though Charles earnestly pressed the French government to renew the attempt, he failed; whereupon he directed his attention to private efforts, and with difficulty was prevented from sailing to Scotland in a fishing boat. In 1745, having obtained some assistance from individuals of British origin in France, he fitted out 2 vessels—the *Elizabeth* of 67 guns, and the *Doutelle* of 16—and placing a quantity of arms and ammunition on board of them, sailed for Scotland, accompanied by a few friends. Of money, he had less than \$20,000. The *Elizabeth* was brought to action by a British cruiser, and was compelled to fly. This was a serious loss, as most of the stores were in her. The *Doutelle* escaped, and, after some adventures, Charles landed at Moidart, July 25, where he was joined by a few persons, whose numbers were soon increased; the most prominent of the highland chiefs being Donald Cameron the younger of Lochiel. The Stuart standard was raised at Glenfinnan, Aug. 19. His army now rapidly increased, many clans rising in his behalf. He baffled Sir John Cope, the royal general, descended upon the lowlands, entered Perth, and took possession of Edinburgh, Sept. 17. The lowlanders who joined him were not numerous, most of them, as one of their number pithily expressed it, having resolved to wait and see which side the hang-man should take before making up their minds. Even of the few leading men who gave in their adhesion, many were probably in the condition of Lord Balmerino, who said that he was so poor he would have joined the Mogul had he set up his standard in Scotland. The victory of

Hadamuir, won Sept. 21, in which Cope's army was annihilated by the highlanders in 5 minutes, raised the prestige of Charles's arms, and he was enabled to march into England at the head of 6,000 men, entering that country Nov. 8.

He took Carlisle, and penetrated to Swarkstone Bridge, 6 m. beyond Derby, and 94 from London, without encountering any opposition, his superior military genius enabling him to rattle the English army under Wade. But when he met no opposition, neither was his force increased, save by a few individuals, most of whom were of the lowest rank. The English nobility at that time contained many Jacobites, and they were still more numerous among the gentry; yet they remained quiet, when the example of a few leading men among them would have caused an extensive rising and a change of dynasty. Most of them were like Dr. Dryasdust's uncle, who, as his nephew

said, "so little esteemed personal safety, in comparison with high church principle, that he waited but the news of the adventurer's reaching London to hasten to join his standard." Discouraged by this coldness, the chiefs compelled Charles to return to Scotland, where a new army had been formed, partly composed of troops from France, and partly of native levies. Charles was bitterly opposed to this course, and the view he took showed his superiority. Had the army pressed forward, London would have fallen into its hands. On the retreat, the insurgents evinced

their usual military preëminence, outmarching even their mounted enemies, and inflicting a bloody repulse upon them at Clifton. They took Glasgow after their return, and defeated the English army, commanded by Hawley, Jan. 17, at Falkirk. The duke of Cumberland was then sent to Scotland, and Charles was compelled to retreat again, much against his will. Toward the middle of April, 1746, the 2 armies were near to one another, and Charles planned a night attack on Cumberland, which failed because of want of due information respecting the country. On April 16 was fought the battle of Culloden, which was as fatal to the prince's character for generalship as to the fortunes of his house. With a fatigued, starved, and diminished army, he awaited the attack of the superior forces of the royal army, the latter being well supplied with every thing to render them efficient. At first the action was one of artillery only, in which the highlanders suffered terribly. At length their right wing charged, swept away a large portion of the 1st English line, and was itself almost annihilated by the fire and bayonets of the 2d line. Even then the royal army would have been defeated, had the Macdonalds imitated the daring bravery of the MacLeans, Frasers, MacIntoshes, Stuarts, and Camerons; but, angry because they had been placed on the left, whereas they claimed the right as theirs from the day of Bannockburn, they refused to charge, and gave the enemy victory. Culloden was the last battle fought

for the fated line. Charles fled, and after 5 months of the most romantic wanderings he escaped to France, where he was well received, the king, for the first time, personally welcoming him. He was a great favorite at court. Some faint show was made of renewing the attempt to invade England, but Charles refused to promise to cede Ireland to France in the event of success, and the plan fell through. He visited Madrid in 1747, and was well received. In 1748 he was expelled from France under insulting circumstances, in compliance with the terms of the peace of Aix la Chapelle. This treatment he had brought upon himself, for the French government had sought in every way to avoid extremities, and nothing but the prince's obstinacy made violence necessary. He was also compelled to leave Avignon, and refused a home in Venice. He visited Germany, and afterward resided for some time in the duchy of Bouillon. He became a Protestant in or about 1752. He was engaged in some Jacobite conspiracies, and visited London in 1750 and in 1758. The story that he was present at the coronation of George III. is slenderly supported. He finally took up his residence in Florence. His father dying in 1766, he became the legitimate king of Great Britain. This title he never assumed, but was known as the count of Albany, which designation he had borne as early as 1784. He married in 1772 the princess Louisa of Stolberg-Gedern, who was more than 30 years his junior. The only effect of this marriage was to add domestic misery to the sufferings of the prince; his name is to be found in the long list of distinguished men who have been dishonored husbands. Alfieri was the princess's lover. She fled from her husband, and a judicial separation took place in 1788. The fact that the prince was intemperate in his last days has often been dwelt on, and it has been said that he fell into the habit of using spirits during his Scottish wanderings. Drunkenness, however, was the vice of the higher classes of that age, and was common with men who had never known hardship or misfortune; but Charles's position attracted attention to all that he did, and men contrasted his conduct with his pretensions and earlier career. His last years were spent at Rome, where he died on the anniversary of the execution of his great-grandfather, though most accounts place the event on the following day. He left an illegitimate daughter, who survived him but a year. He was one of those rare characters who bear prosperity better than adversity. His talents were high, and no member of the Stuart family ever exhibited more practical ability. His conduct in the campaign of 1745-'46 evinced an original genius for war. He found himself in circumstances entirely new, and he adapted himself to them with all the facility of genius.—The history of Charles, and of his Scottish campaign, has been written by many eminent men—by Scott, R. Chambers, Pichot, J. H. Jesse, Earl Stanhope, C. L. Klose, and others. There is

much curious matter respecting the conduct of the Jacobites, and of the prince and his family, in the "Memoirs of Sir R. Strange, and of Andrew Lumisden," by Mr. Dennistoun, Mr. Lumisden having been private secretary to both Charles and his father. In the early years of the 19th century the interest in the history of "the young pretender" was renewed by the writings of Scott, who has introduced him into 2 of his novels, "Waverley" and "Redgauntlet." Scott had known many Jacobites, and wrote of "the forty-five" and subsequent crises in their history from positive knowledge; and though he was a constitutionalist, his amiable nature caused him to sympathize with the members of a fallen party.

**CHARLES RIVER**, a winding stream rising in Worcester co., Mass., flowing through Norfolk and Middlesex. It meets the tide waters and forms part of Boston harbor. Navigable to Watertown, 7 m. W. of Boston.

**CHARLES'S WAIN**, a name given to the constellation Ursa Major, or the Great Bear, often called also the Dipper. The literal meaning of the name is the rustic's wagon, and some fancied resemblance doubtless was the occasion of its use.

**CHARLESTON**, a district of South Carolina, bordering on the Atlantic; area 1,906 sq. m.; pop. in 1850, 72,805, of whom 44,376 were slaves; in 1858, estimated at 100,000, of whom 60,000 are slaves. The Santee river bounds it on the N. N. E., and it is drained by Ashley and Cooper rivers, which unite to form the harbor of Charleston. The other chief river is the Edisto, beside which there are numerous inlets, including Charleston harbor, N. and S. Edisto, and S. Santee. These are generally navigable by small craft. The coast is broken by several bays and protected by a stretch of sandy islands. The surface is low, level, and in some places exposed to inundation. The soil embraces every variety, from the richest alluvial mould to the most sterile sand. There are large quantities of waste land, most of it reclaimable. The famous sea island cotton is grown along the rivers and coast. In former periods indigo, tobacco, silk, and wine were extensively produced. The olive, orange, and lemon have been found to mature in the open air, though cut down by occasional very severe winters. The palmetto and the pine are among the indigenous forest trees. The productions in 1850 were 318,737 bushels of Indian corn, 498,972 of sweet potatoes, 15,700,603 lbs. of rice, and 4,221 bales of cotton. There were 22 corn and flour mills, 8 saw mills, 1 cotton factory, 2 tanneries, 12 printing offices issuing 14 periodicals, 92 churches, 3 colleges, 50 academies, and 1,196 pupils attending public schools. The South Carolina railroad, which terminates at Charleston city, runs through this district; a communication between the Santee and Cooper rivers has also been opened by a canal 22 m. long. This is by far the most populous district of the state. Several battles during the revolution,

including those of Eutaw and Fort Moultrie, were fought in this district. Capital, Charleston.

**CHARLESTON**, the capital of the district or county of the same name, in the state of South Carolina, and the chief commercial city of that state, stands at the confluence of the two rivers, Ashley and Cooper, which here unite and form a spacious and beautiful bay. These rivers run a parallel course for nearly 6 m., widening as they approach the sea, thus gradually narrowing the site of the city into a complete peninsula. Here, spreading over an ample area, and blending with the Atlantic, they make one of the most capacious of harbors, landlocked on all sides except one, on the east, from whence the sea pours in. The extent of the bay is ample for all the commercial purposes of a great city. The *coup d'œil* constitutes a beautiful picture, which might compare with any in the world, but for the lack of background, and of the relief afforded by contiguous eminences. The lands around, and that upon which the city is built, are all equally low and level, rising only a few feet above the sea. The dwellings seem to emerge from the water, and at a little distance the shore line becomes indistinct. The width of the inner harbor, at its mouth, is something over a mile. The passage is defended by 3 fortresses, well placed to resist the approaches of an enemy. On the right hand, at the entrance, is Fort Moultrie, on Sullivan's island, occupying the site of that memorable fortress, Sullivan, which, on June 28, 1776, lost off the British fleet of Sir Peter Parker, in one of the most brilliant fights of the revolution. On the left hand, raised upon a mole in the harbor, and directly covering the channel, is Fortress Sumter, a recent erection, and one of the best built forts of the United States. Immediately in front of the city, and but a mile from it, is Castle Pinckney, covering the crest of a mud shoal, and facing the entrance. The approaches are thus probably as well defended as they can be by such structures, and under the present greatly advanced system of offensive warfare. As against shipping, before the application of steam, there could be little doubt of the perfect efficiency of these 3 structures for the defence of the harbor. The outer harbor, lying within the bar, extends from Sullivan's island to the south channel, below the lighthouse, a distance of 6 m. The bar is the most serious obstruction to the commercial prosperity of Charleston. This consists of successive ranges of sand banks, which stretch away before the entrance for several leagues; and as these ranges consist in part of quicksand, they are liable, from storms and undercurrents, to occasional change of locality, greatly increasing the difficulty of pilotage. Between these successive ranges of sand are formed several channels of varying depths of water. Until recently those in use were but 3: the ship channel, with 16 feet water at ebb; the small or middle channel, with 14; and Lawford's, or the

with channel, with but 10 feet. Recently, a fourth channel has been discovered, called Maffitt's from the discoverer, an officer engaged in the coast survey. This brings the vessels close in to the shores of Sullivan's island, is free from shoals, is of bolder cut and more direct passage, and promises in a great degree to overcome, if not entirely overcome, the impediments of the entrance, which have so seriously retarded the commerce of the port. Efforts are now in progress to increase the depth and utility of the Maffitt channel, by bringing art to the help of nature. A dredge steamer of great power, which works by suction, is employed daily in removing sand and mud from the bed of the channel, and with the most encouraging results. Already, the largest ships that frequent the harbor give it the preference over all others. Buoys are set at proper distances, and knowledge of the bearings of the lights and beacons will make the entrance easy. The best of these channels may, at high water, give a depth of 18 or 20 feet. The average rise of the tide upon the coast is about 7 feet. The ship channel is  $11\frac{1}{2}$  m. from the city, the middle channel, while that of Maffitt is probably still nearer. The approach to the coast is easy enough, the shoaling gradual, and with proper care and good seamanship, the soundings alone would ensure the mariner of safety. The lights along the coast of this district begin at the well-known Cape Roman; there is a light at Bull's, and floating lights and bell-boats contribute to disarm all the dangers of the coast. The lighthouse at the entrance of Charleston harbor is on a Lighthouse island, and W. of the ship channel, lat.  $82^{\circ} 41' 55''$  N., long.  $79^{\circ} 52' 29''$  W. The tower is of brick (white), 110 feet high; the light is at an elevation of 183 feet above the sea. It may be seen at a distance, in good weather, of 20 nautical miles. Until recently the light was revolving; it is now stationary. This light, and the beacon in front of it, are used as a range for crossing the bar of the main or ship channel. The beacon in front of the main light is also fixed. It is visible at a distance of 10 nautical miles. The color of the tower is red. The height of the light above the sea level is 50 feet. There are beacons also on Morris and Sullivan's islands, at Fort Sumter, Castle Pinckney, Mount Pleasant, and on the battery at White point, all within the harbor. The beacon on Morris island is with the outer bar of the small channel; those on Sullivan's have a channel range leading from the main ship channel into the harbor; the Castle Pinckney light is red; that on Mount Pleasant is in course of erection. The battery beacon, at the E. end of the city, is a shaft of bronzed iron, and with Fort Sumter light forms a range to enter the N. channel; it is lighted by gas. From the entrance of the middle channel you command a full view of the city, guided by the spire of St. Michael's church, which bears from this point about N.  $68^{\circ}$  W. This spire was the only prominent landmark con-

ducting to the city previous to and throughout the revolution. To prevent its use by the British in making their approaches, the city authorities had it painted black, but the enemy found black quite as demonstrative as white, and alleged that the change of color really helped their pilotage.—The city of Charleston is situated in lat.  $82^{\circ} 46' 38''$  N. and long.  $79^{\circ} 55' 38''$  W.; 125 m. S. S. E. from Columbia, the capital of the state; 110 from Savannah, Ga.; 165 from Washington, N. C.; 547 from Washington, D. C.; 587 from Baltimore, 684 from Philadelphia, 778 from New York, and 989 from Boston; with all which places it connects by railroads, and there are steamship lines to Baltimore, Philadelphia, New York, Savannah, Florida, and the island of Cuba. Railroads emerging from the city pass into the heart of the state, penetrate the mountain region, and with their numerous branches extend for nearly 1,000 miles, forming connections with the neighboring states of North Carolina, Georgia, Tennessee, and Mississippi, with all of which it carries on an extensive trade. Hence it is that Charleston is one of the great marts in all the South for the great staples of that region, cotton, rice, tobacco, indigo, grain, bacon, wheat, tar, pitch, turpentine, and lumber; and recently, to a remarkable degree, for vegetables and fruit, with which through steamships she largely supplies New York and other northern cities. In the immediate precincts are grown the fine cotton of the sea islands, and the largest rice crops of the United States. A brief summary of the exports in rice and cotton alone, through a term of years, will better serve to show its rank as a place of commerce, and we give a statement thereof for 5 successive years, ending Aug. 31 :

Years.	Upland Cotton, bales.	Sea Islands Cotton, bales.	Clean Rice, thousand.	Equivalent to
1854	408,658	24,766	125,524	Crop of 1858
1855	495,251	24,451	98,008	" 1854
1856	485,814	23,059	127,756	" 1855
1857	375,064	23,469	120,873	" 1856
1858	391,705	25,668	128,340	" 1857

The tonnage of the port in 1852 was 43,000 tons shipping. But the domestic shipping bears no proportion to the resources of the city. The banking facilities of Charleston consist of 6 incorporated banks, each of \$1,000,000 capital; one of \$872,475; one of \$3,160,800; and the bank of the state (a state institution), whose strict capital is \$1,090,977, but which discounts beside on sundry loans made by the state government, these latter varying from time to time; at the present period these sums amount to \$3,461,620. We thus make the aggregate banking capital of the city, as incorporated, on Oct. 1, 1858 :

Six banks of \$1,000,000 each.....	\$6,000,000
Railroad bank.....	872,475
Bank of Charleston.....	3,160,800
Bank of the state of S. Carolina.....	4,528,397

Total.....\$14,561,672

The present permanent population of Charles-

ton is about 65,000, of whom probably  $\frac{1}{4}$  are blacks and colored. It is on the increase, and the city is gradually spreading over the whole space between the 2 rivers, its entire length of 8 miles, and beyond this there is a growing suburb. For a long period, from 1830 to 1840, the growth of the city was imperceptible. Since that period,  $\frac{1}{4}$  has been added to the population. The incorporation within a few years of that portion of the population which dwelt without the corporate limits, called the Neck, has doubled the number of the wards, which are now 8, represented by 16 aldermen, and a mayor.—The city institutions are numerous, including, in addition to those which usually belong to municipalities, several charitable foundations, such as an orphan asylum, where 200 or 300 orphans of both sexes are nurtured and educated; poor-house, dispensaries, and hospitals. The city police consists of a day and night guard of about 100 men,  $\frac{1}{4}$  of whom are mounted. Among the endowments of the municipality are a high school and college, both of which possess a very high local reputation. The schools of local or private endowment are several, and well conducted, and the state legislature appropriates largely to the common school system, which has recently undergone great improvements, with an equal increase of efficiency and popularity. Of the several churches of the city, there are 10 Protestant Episcopal, 5 Presbyterian, 5 Methodist Episcopal, 8 Baptist, 1 French Protestant, 3 German Lutheran, 8 Roman Catholic, 2 Congregational, 3 Jewish synagogues, 1 Unitarian, 1 Methodist Protestant, 1 mariners', 1 New Jerusalem (Swedenborgian). Some of these churches are for black and colored worshippers. In all of them are galleries or other parts of the house assigned to slaves. The militia of Charleston constitutes the 2d division of the state military organization. It consists of 2 regiments of infantry (16th and 17th), a regiment of artillery (1st), a battalion of rifles, and a squadron of horse. The fire department is large and efficient, consisting of 12 volunteer companies, with their own engines, and 10 engines beside, belonging to the corporation, the officers of which are appointed by the city. The societies and clubs are very numerous.—Charleston is the second congressional district of the state, and sends one member to the federal congress. She has 2 senators and 17 representatives in the legislature of the state. There are several public libraries. The Charleston library (a society of private stockholders) contains probably 25,000 volumes, and is especially rich in works of natural history. The college library, the mercantile, apprentices', and other libraries, have each considerable and valuable collections. There is a medical college of high reputation, and 2 preparatory seminaries or schools of medicine. There is also an academy of art and a historical society, which has accumulated much valuable material.—The occupations of the people of Charleston are chiefly those of trade (including a large commission business) and the mechanic

arts. There are few manufactures, and these on a limited scale. The South Carolina institute, by public fairs and premiums, has been working auspiciously of late years, under the joint patronage of state and city, with a hope to give a new impulse to the arts, including in its objects every branch of mechanics, manufactures, and agriculture. It has a fine edifice in Charleston, and there is an annual exhibition. There is some ship building carried on, and there are 2 dry docks for repairs. But the capital of the state is mostly employed in agriculture, and that of the city in trade. A large proportion of the population of Charleston consists of the gentry of the contiguous parishes, who, possessing large planting interests, are sufficiently opulent to maintain abodes in the city as well as on their plantations. Here they educate their children, and hither they resort in midsummer. This is the secret of something anomalous in the life of Charleston. It is resorted to in summer as a watering place by the people of the country. This practice will account for some of the characteristics which are thought to be peculiar to the city. The planters bring with them wealth and leisure, and these naturally beget luxurious tastes and habits. These elevate the tone of the society, but tend to the displacement of labor and industry. Hence extravagant standards of living, and deficient enterprise as well as industry.—The city covers a considerable extent of territory, more than its number of people would seem to imply, as in other cities, in consequence of the suburban character of so many of the residents. The dwelling houses of these are generally isolated, having large open grounds on every side, which are used for gardens. Rare exotics, the fine fruits, the peach, the nectarine, the orange, fill these spaces, and, with the vine, impart a rich tropical character to the aspect of the abode, which itself may be neither very large nor very magnificent. Ample piazzas and verandas, ranging from 1 to 8 stories, give coolness and shade to the dwelling.—The corporate limits of Charleston extend from Battery or Wharfe point, on the extreme southern verge of the city, to an arbitrary line on the north, fully 8 miles above. The same limits, according to the usual mode of building in northern cities, would contain 800,000 or 400,000 people. The city is laid out with tolerable regularity. The streets, with few exceptions, cross at right angles. The 2 principal, King and Meeting, run N. and S., nearly parallel, the whole length of the city, but converge to intersection at or about the northern limits. Meeting street is a fine, broad avenue of 60 feet, having on it a large proportion of the public buildings, and doing a large share of the wholesale trade. King street, too narrow for its uses, is the fashionable shopping street. The cross streets extend from E. to W., from Cooper to Ashley river, and are generally too narrow for health, though the opinion 100 years ago preferred narrow to wide streets, as affording shade, and as giving more volume and force

the progress of the breeze. The houses are of brick or wood; there are few of stone. In a few years a city ordinance required that new buildings should be made of wood; but this regulation applies only to the old city, the limits on the north were Calhoun street. The upper part of the present city, formerly the town, has been incorporated recently, and in consequence of peculiar conditions in the locality, the limited settlement, and the suburban character of the population, there was a modification of this law, leaving them free to erect wooden structures for a period of 20 years. Charleston exhibits a peculiar taste in architecture.

It is like no other city in the union in this respect. No people could be more individually independent of each other. There are few large blocks or rows of buildings. There is no uniformity. Each man has built after his own fashion, and there are some singular emanations of taste; but what is lost in propriety is gained in variety, and, with fine gardens, lawns, plats of shrubbery, shade and fruit trees, orange, peach, &c., creepers, vines, the richness of the magnolia, the oak, the cedar, the cypress of India, girdling the white dwellings, the green verandahs, the effect is grateful and highly picturesque. There are few public squares in Charleston, and these are generally small; there is less necessity for them here than in cities where the dwellings are crowded together; a large portion of the private residences may be said, each, to have its square. Hall square is insignificant; Citadel square is a moderately large parade; and in the upper part of the city there are several small enclosures, equal to a block each, which are attractive though not much frequented. The principal public buildings are the citadel, the orphan house, the court-house, Roper hospital, the old and new town-houses, and the churches, especially St. Philip's, St. Michael's, the Catholic cathedral, the Baptist (Citadel square), central, and others. Outside of the city, on the N. boundary, is the Magnolia cemetery, a beautiful and well-designed "city of the silent," in which there are some fine monuments.—Charleston was originally settled about 1679, by an English settler, with an English charter, under William Oglethorpe, who became first governor. He first attempted a settlement at Beaufort, but abandoned this place in consequence of its insecurity. It was too easily accessible by sea, too difficult of defence in a period when England had several time competitors. Sayle transplanted his colony next to the W. side of Ashley river. Shortly after his death, another removal took place, and the colonists passed over E. of the river, and planted themselves on the W. side of the Cooper; and Oyster Point became the new Charleston. Its history, from that period to the close of the revolution, nearly 100 years, is full of curious and remarkable interest. Its conflicts with the tribes of red men by which it was surrounded; its devastations by war and fire; the terrible scourge which for

so long it endured from the fierce fevers of the low latitudes; the poverty of the early settlers; the niggardly help given by the lords proprietors; its civil commotions, in which finally it exchanged their government for that of the crown; and, subsequently, its conflict with the crown itself, at the period when the colonies generally threw off their allegiance; these are heads of chapters of exciting and instructive interest. Charleston was one of the first of the chief places of the South to assert a common cause with and for the colonies. It was the first to assert its own independence, and to make a constitution for itself. It was thrice attempted by the enemy: first in the fierce assault by Sir Peter Parker and Commodore Arbuthnot on the Palmetto fort at Sullivan's island, when the British fleet and army were beaten off, and almost destroyed; next by the attempted *coup de main* of Gen. Prevost; and thirdly, in the regular leaguer of the city by Sir Henry Clinton, when it stood a siege of 6 weeks by 12,000 British regulars, and succumbed at last to famine. But these details must be sought in other volumes, and in the history of the state at large.

CHARLESTOWN, the 4th city of Massachusetts, in Middlesex co., is one of the oldest places in that state, dating from 1628, though Frothingham, the local historian, is of opinion that July 4, 1629, is the only date for the foundation of the town for which good authority can be adduced. The Indian name is *Mishawun*. It is a peninsula formed by the rivers Mystic and Charles, connecting with the mainland by a very narrow isthmus. Originally the town territory was large, but from it have been taken Woburn, Stoneham, Burlington, Somerville, Malden, much of Medford, and portions of Cambridge, West Cambridge, and Reading, leaving it the smallest town, in dimensions, in Massachusetts. It is connected with Boston by the Charles river and Warren bridges, so that the two places form but one community in most social and business respects. It forms a part of the Boston port of entry. It is a handsome city, and its appearance favorably impresses strangers. It is one of the most interesting spots in American history. A flourishing and noted place in the colonial period, it became conspicuous at the very commencement of the revolution, as well from political as from military circumstances. The British force that fled from Concord and Lexington fell back upon Charlestown, and Gen. Gage threatened to destroy the place if the troops were molested. Most of the inhabitants left their homes, so that on June 17, 1775, when the town was destroyed, not above a tenth part of their number were present. The resolution to fortify Bunker hill, in Charlestown, taken by the Massachusetts committee of safety, led to the battle of that name, which, after making due allowance for patriotic exaggeration, was one of the most important actions ever fought, because of the moral effect it pro-

duced on the nominal victors. It was in course of this battle, and as one of its incidents, that Charlestown was destroyed. This act is often spoken of as if it were one of pure wantonness, but the English officers defended their conduct on grounds of military necessity. Gen. Howe, who commanded the force actively employed, declared that he was annoyed by musketry from Charlestown, and sent word to Clinton to fire the place, which was done by a discharge of shells from Copp's hill in Boston, and by men who were landed for the purpose. The destruction was complete within the peninsula, with the exception of a few houses. Gen. Gage had resolved to burn the town should the Americans erect any works on the hills within its limits. The number of buildings destroyed was about 400, and the value of the property was estimated at more than \$500,000. Burgoyne's rhetorical description of the event has added much to its notoriety. In 1825 the corner stone of Bunker hill monument was laid, which was completed 18 years later. (See BUNKER HILL.) Charlestown appears to have recovered very slowly from the effect of the blow it received in 1775. In 1765, its population by census was 2,031, but in 1790 it was only 1,583, and in 1800 it was 2,751, which did not vary much, we may suppose, from what it had been at the beginning of the war. By the census of 1810 the inhabitants numbered 4,959; by that of 1820, 6,591; that of 1830, 8,783; that of 1840, 11,484. The state census of 1855 showed a population of 21,700, of whom 5,168 were foreigners. The number of voters in 1857 was 8,411. Charles river bridge, connecting the town with Boston, was completed in 1786, and Warren bridge in 1828.—Charlestown is a place of considerable business, of a various character. The principal manufactures are chairs and cabinet ware, lead, soap and candles, leather, lumber, upholstery, steam engines and boilers, railroad cars and other vehicles, boots and shoes, tin ware, whips, stone and earthenware, casks, pickles and preserves, bread, clothing, morocco, gas, chemical preparations, quarried stone, brushes, spirits and beer, blacksmiths' work, willow ware, cigars, snuff, brass ware, mechanics' tools, combs, lime, trunks, masts and spars, boats, saddles, harness, blocks and pumps, silver ware, &c. The commerce of Charlestown is included in the Boston returns. The place has been connected with the ice trade from an early day, and great numbers of vessels are annually laden with ice at its wharves. According to the official returns of 1855, there was then \$600,000 invested in the business, and the number of tons of ice taken was 186,000. The state valuation in 1850 showed the property of Charlestown to be worth \$8,624,690. It is now \$14,048,800. The number of dwelling houses in 1850 was 2,186, and in 1855 it was 8,126. The Boston and Fitchburg railroad company formerly had both their passenger and business stations for Boston at Charlestown, but the passenger station was removed to Boston in 1848, and

their lands at Charlestown are now devoted to the merchandise station, and to extensive arrangements for manufactures and repairs. The Massachusetts state prison, which was founded in 1800, is in Charlestown, on a point of land near East Cambridge. The number of prisoners there on Sept 15, 1858, was 485. The institution has been very successfully governed, and is now under the charge of Mr. Giles Haynes, who was appointed warden in 1851. The McLean asylum for the insane, which was formerly in Charlestown, is now in Somerville, which was incorporated in 1842, and is composed of territory which made part of Charlestown until that date. One of the best navy yards belonging to the United States is at Charlestown, where it was established in 1779. It is on the N. side of Charles river, is enclosed by a high wall of great strength, and covers about 60 acres. The yard contains several dwelling houses, numerous store houses, rope walks, machine shops, ship houses, &c. The dry dock is a fine work, and cost nearly \$700,000. Its length is 341 feet, width 60, and depth 30. Some of the best ships belonging to the national marine were built at this yard, among them being the Independence, the Merrimack, the Jamestown, the Cumberland, and others. Extensive repairs of vessels are there made, and in the summer of 1858 there were 1,550 men employed in the yard. The naval hospital connected with the yard is at Chelsea. Charlestown has 2 banks, with capitals of \$500,000, 1 insurance company, and 2 savings banks. There are 12 churches, belonging to Baptist, Methodists, Unitarians, Universalists, Roman Catholics, and Orthodox Congregationalists. There are 89 public schools in Charlestown, attended by 4,435 scholars, and having 19 male and 61 female teachers. The city raises \$25,000 annually for schools. There is an incorporated academy, with 140 pupils; and the number of other academies and private schools is 5, with an average attendance of 123. The fire department consists of 6 engine companies, 1 hose company, and 1 hook and ladder company. The government is in the hands of a board of 6 aldermen and 18 councilmen, and a mayor. Charlestown forms a part of the first senatorial district of Middlesex co., which elects 1 state senator, and is divided into 3 representative districts, the 1st (ward 1) electing 1 member, and the 2d (wards 2 and 3), 2 members of the state house of representatives. The history of Charlestown down to the date of the battle of Bunker Hill has been well written by Mr. R. Frothingham, jr., one of the editors of the "Boston Post."

CHARLESTOWN, the capital of Jefferson co., Va., a thriving post village on the Winchester and Potomac railroad; pop. about 1,800. It is situated in the region called the valley of Virginia, and is surrounded by a beautiful and fertile country. The land on which the town is built formerly belonged to Col. Charles Washington, the brother of Gen. Washington, and the place was for some time his residence.

CHARLETON, ROBERT M., an American lawyer and author, born at Savannah, Ga., Jan. 19, 1807, died in the same city, Jan. 8, 1854. Early admitted to the bar, he became successively member of the state legislature, United States district attorney, in 1834 judge of the supreme court of the eastern district of Georgia, and in 1852 United States senator. The best known of his writings for periodicals are the "Leaves from the Portfolio of a Georgia Lawyer," which appeared in the "Knickerbocker Magazine." In 1839 he published a volume of poems, including the poetical remains of a deceased brother, the second edition of which, containing also 2 prose addresses, appeared in 1842. He was esteemed for his finished oratory and genial social powers.

CHARLEVILLE (anc. *Arca Remensis, Caropolis*), a French town, noted for its beauty, in the department of Ardennes (Champagne), situated on the Meuse, about a mile N. of Mézières, and connected with that town by an avenue and suspension bridge; pop. 9,162. It was a military station until the end of the 17th century, when its fortifications were destroyed, and subsequently the royal manufactory of arms was removed. The prosperity of the town has since increased. It has an active export trade in wine, spirits, coal, iron, and slates; a manufactory of muskets, nail works, copper foundries, and tanneries; a commodious port, a public library of 22,000 volumes, a college, an ecclesiastical school, and a theatre.

CHARLEVOIX, a N. W. county of the S. peninsula of Michigan, bordering on Lake Michigan, and having an estimated area of 620 sq. m. Its W. shore is deeply indented by Little Traverse bay, and 2 or 3 considerable lakes lie wholly or partly within its boundaries. It has been formed since the last census (that of 1850) was taken.

CHARLEVOIX, PIERRE FRANÇOIS XAVIER DE, a French historian and traveller, born Oct. 29, 1682, at St. Quentin, died Feb. 1, 1761, at Laflèche. After being professor of Latin literature and philosophy in the colleges of the order of Jesuits, of which he was a member, he was sent a missionary to Canada. He ascended the St. Lawrence, travelled through the country of the Illinois, and descended the Mississippi to its mouth. In 1722 he visited St. Domingo, and after his return to France was during 20 years a contributor to the *Journal de Trévoux*. His principal works are: *Histoire et Description du Japon*; *Histoire de l'île Espagnole ou de Saint Dominique*; *Histoire du Paraguay*; and *Histoire de la Nouvelle France*. The last named work is often referred to by American historians.

CHARLOTTE, a S. W. county of New Brunswick, separated from Maine on the W. and S. W. by the St. Croix river, bounded S. by the bay of Fundy and Passamaquoddy bay; area 1,250 sq. m.; pop. in 1851, 19,938. It is drained by several rivers, emptying into the bay of Fundy, and includes Grand Manan, Campo

Bello, and Deer islands. It has a fertile soil, but the inhabitants attend more to commerce, ship building, and the fisheries than to agriculture. The productions in 1851 were 8,263 bushels of wheat, 409 of Indian corn, 69,998 of oats, and 168,117 of potatoes. There were 102 saw mills, 14 grist mills, 4 tanneries, 6 woollen factories, 1 iron foundry, 58 churches, and 2,912 pupils attending schools. Capital, St. Andrew's.

CHARLOTTE, a S. E. co. of Va.; area 550 sq. m.; pop. in 1850, 13,955, of whom 8,988 were slaves. The surface is hilly; the productions in 1850 were 8,868,040 lbs. of tobacco, 872,867 bushels of corn, 85,658 of wheat, and 171,872 of oats. There were 436 pupils in the public schools, and 25 churches. The county was formed from part of Lunenburg in 1794. Capital, Marysville.

CHARLOTTE, a thriving town on Sugar creek, and capital of Mecklenburg co., N. C. It is the terminus of the Charlotte and South Carolina railroad, and of the Central railroad of North Carolina. A plank road 120 m. long connects it with Fayetteville. The town is situated upon the gold range of the Atlantic states, and its prosperity is principally owing to the working of the mines in its vicinity. (See GOLD.) A branch mint was established here in the year 1838 for coining gold. Pop. in 1853, about 2,500.

CHARLOTTE AMALIE, or ST. THOMAS, the capital of the island of St. Thomas, Danish West Indies. It has an excellent harbor, and is built on 8 hills, which are spurs of a mountain rising immediately in the rear of the town. The citadel of Christian's Fort and 2 batteries are its chief defences. This town possesses considerable trade, and contains a number of churches and chapels belonging to various denominations, and a Jewish synagogue. Pop. estimated at about 12,000.

CHARLOTTE AUGUSTA, commonly called Princess Charlotte, daughter of Queen Caroline and George IV., born at Carlton house, Jan. 7, 1796, died at Claremont, Nov. 6, 1817. At an early age she was placed under the care of the bishop of Exeter and Lady Clifford, and became one of the most accomplished princesses of her day. The prince of Orange was proposed to her as husband, but she bestowed her affections upon Prince Leopold of Saxe-Coburg (who in 1831 became king of Belgium). She married him May 2, 1816, and they took up their residence at Claremont, where she died after having been delivered of a still-born child. Her death caused universal grief in England, and the physician who had attended her committed suicide in despair.

CHARLOTTE HARBOR, or BOCA GRANDE, an inlet on the W. coast of Florida, about 25 m. long, from 8 to 10 m. wide, but only 10 or 12 feet deep. Its entrance, which lies between Boca Grande key and Gasparilla bay, is  $\frac{1}{2}$  of a mile wide and 6 fathoms deep. This harbor is sheltered from the sea by several islands, and

produces the finest oysters and the greatest variety of fish, wild fowl, and deer, of any part of the coast.

CHARLOTTE TOWN, the capital of Prince Edward island, is situated in Queen's co., at the junction of Hillsborough river with the York river; pop. nearly 5,000. It has a good harbor, is well built, contains the so-called colonial buildings, with accommodations for the legislature and courts of law, the old court house, an Episcopal church, Scotch church, a Baptist chapel, a Methodist chapel, a Roman Catholic church, an asylum for lunatics and poor, an academy, and a national school.

CHARLOTTENBURG, a handsome town in the Prussian province of Brandenburg, government of Potsdam, and circle of Teltow, on the left bank of the river Spree, connected with Berlin by a fine promenade, which is lighted at night, the distance being only about 4 miles; pop. about 9,000. The place takes its name from Sophia Charlotte, the queen of Frederic William I., who in 1706 caused a palace to be built there. Frederic the Great added a new château, and endowed it with a valuable gallery of art, which, however, especially the part which contained the paintings, was injured by the Austrians in 1760.

CHARLOTTESVILLE, a town of Virginia, capital of Albemarle co., on Moore's creek, 2 m. above its entrance into Rivanna river, and 81 m. N. W. of Richmond; pop. in 1853, 2,600. Its chief importance is due to its being the seat of the university of Virginia, an institution planned by Mr. Jefferson, founded in 1819, and whose buildings were erected at an expense of over \$200,000. (See VIRGINIA, UNIVERSITY OF.)

CHARM (Lat. *carmen*, a verse, a song, or a charm), a word used in necromancy to designate a power or spell exercised in an occult manner, by which the will and action of the charmed person are enchained. In ancient times charming was supposed to be effected by the assistance of the devil. The Scriptures (Deut. xviii. 11) place it in the same category with sorcery, witchcraft, and necromancy, and treating them all as acknowledged facts, forbid them to be practised. The charm was supposed to be accomplished by placing words or sometimes things in a certain arrangement (hence the name). The charming of serpents is also mentioned in Scripture. Something of the kind is still practised among the jugglers of India.

CHARNEL, or CHARNEL HOUSE, originally a place for depositing flesh, a larder, but now generally used to denote a receptacle for the dead, usually near or in a church.

CHARON, in Greek mythology, son of Erebus and Nox, the ferryman who transported the souls of the dead over the river Acheron to the infernal regions. The fee exacted for this service from each spirit ferried over by him was never less than 1 obolus, nor more than 8. The spirits of those who had not been honored with a funeral were not permitted to enter Charon's boat without having previously wandered

on the shore for a century; nor could any living person be admitted into it till he had shown its master a golden branch, the gift of the Cæmæan sybil. The ferryman was once imprisoned for a whole year for having conveyed Hercules across in violation of this rule, even though he had been compelled by the hero to do so. Charon is generally represented as a robust old man of stern countenance, his eyes glowing like flame, his hair white and bushy, and in his hands a pole to direct his boat on her course.

CHAROST, ARMAND JOSEPH DE BÉTHUNE, duke, a French philanthropist, a descendant of Sully, born at Versailles, July 1, 1738, died in Paris, Oct. 27, 1800. At a time when nobles were generally addicted to licentious pleasures, he devoted himself to the improvement of agriculture and of the condition of the laboring classes. The peasants on his estates were indebted to him for their emancipation, while he was active in promoting their welfare and education. His influence extended over several provinces of France, and the profligate Louis XV. himself acknowledged his services. When France was exposed to invasion, the duke, although he had little sympathy for the new government, contributed a large sum of money for the common defence. Nevertheless he was arrested and his property confiscated, but he escaped the guillotine.

CHARRAS, JEAN BAPTISTE ADOLFE, a French republican soldier and statesman, born at Pfalzburg, in the department of the Moselle (Lorraine), June 7, 1810, the son of Gen. Charras, took part in the revolution of 1830, was promoted in 1838 to the rank of lieutenant, wrote a series of able articles in the *National* on military affairs, which gave umbrage to the government and caused him to be sent to Algeria; distinguished himself there on the battle field as well as in the training of native troops and the colonization of the country; but, owing to his unpopularity with Louis Philippe's government, he was, after much procrastination, promoted only to the rank of lieutenant-colonel. After the revolution of 1848, he became under secretary of state (April 11), and representative for the department of Puy de Dôme (April 22). He was one of the most zealous members of the national assembly, one of the chief pillars of the republican government, and one of the victims of the *coup d'état* of Dec. 2, 1851. First detained at Ham, he was transported to Belgium in Jan. 1852, but expelled from that country, in Nov. 1854, at the request of Louis Napoleon, whom Charras had denounced on many occasions, but most effectively in a letter of which 50,000 copies were printed in Belgium alone. A pamphlet, *Les trois maréchaux de France* (Brussels, 1855), is also attributed to him. A remarkable work from his pen, *Histoire de la campagne de 1814*, appeared in Nov. 1857, and a second edition soon afterward. Since Dec. 1, 1857, he has been again permitted to reside in Brussels.

**CHARRON, PIERRE**, a French author, born in Paris in 1541, died there, Nov. 16, 1608. His father, a bookseller, had 25 children in all. Pierre studied law at Orleans and Bourges, and had practised already for some years as an attorney when he took holy orders, and soon became noted for his eloquence as a preacher. He filled several ecclesiastical offices in Gascony and Languedoc; was appointed chaplain of Queen Margaret of Navarre; in 1588 returned to Paris, intending to become a monk, but was rejected on account of his age. Remaining a secular priest, he went to Bordeaux, and there became intimately acquainted with Montaigne. Charron is the author of 2 books widely different in their tendency and character. His *Traité des trois vérités*, published for the first time in 1594, is a defence of religion against atheists, of Christianity against other religions, and of Catholics against heretics. In 1601, under the tolerant rule of Henry IV., Charron published his *Traité de la sagesse* (latest edition by Duval, Paris, 1821). To this work, branded by his contemporaries as rank atheism, Charron owes his place in the history of modern philosophy.

**CHART** (Lat. *charta*, paper), a topographical or hydrographical map. Its special design is not to indicate political divisions, nor geological, botanical, or zoological characteristics, but to represent a portion of the earth's superficies *in plano*. The topographical chart is a detailed draught of the superficial shape of a particular district. The hydrographical chart is chiefly for the use of navigators, and describes shores, banks, harbors, sounds, rocks, flats, and other nautical circumstances, with the latitude and longitude of every place. In the plane chart the meridians of longitude and the parallels of latitude are represented as always parallel and equally distant from each other, and therefore the degrees of each are everywhere equal. Mercator's chart differs from this only by representing the distance between the parallels of latitude as increasing in a certain proportion from the equator toward either pole. In the globular chart the proportion of magnitudes and distances is nearly the same as on the globe itself. The distance of the eye from the plane of the meridian on which the projection is made, is regarded as the sine of an angle of 45°, which makes the meridians always equidistant and the parallels nearly so. A selenographic chart represents the phases and spots of the moon.

**CHARTER** (Gr. *χαρτης*, parchment; Lat. *charta*), the name given in the middle ages to every kind of written convention. Among the principal kinds were *chartæ juratæ* or *sacramentales*, by which an engagement was contracted with an oath; *chartæ de muneburda*, by which kings, lords, or bishops granted their protection to corporations, churches, or monasteries; *chartæ apennes*, or *pantochartæ*, by which titles to property were confirmed; *chartæ beneficiaræ*, by which kings and emperors bestowed donations; and *chartæ partitæ* or *indentatæ*, which were common in

England and France, and were marked with indentations or cut asunder, as bank notes are now, in order to guard against counterfeits. The term came gradually to be limited to its modern sense, meaning an instrument by which a king or other sovereign power conferred rights and privileges. Thus many of the early colonies in America had charters from the king of England, by which they were permitted to establish a government, and make laws for their own regulation, which was therefore called a charter government. Among the charters of greatest historical importance are the *magna charta*, the basis of English liberty, which was signed by King John in 1215, and was frequently violated and confirmed by subsequent kings; the charter of peace, which Philip Augustus of France signed in 1222 at Melun, and which settled the relations between the royal officers and the officers of the bishop and chapter of Paris; the Norman charter, granted by Louis X. in 1315, to confirm the rights and privileges which Normandy had enjoyed under its ancient dukes, and which was not abolished till 1789; the constitutional charter, which was the fundamental law of the French realm under the restoration, promulgated by Louis XVIII. in 1814, and which made all authority and executive power reside in the person of the king, and gave legislative power to 2 chambers; and the French charter of 1830, by which the national sovereignty was proclaimed, which was voted by the chamber of deputies, Aug. 7, 1830, and accepted by King Louis Philippe on the following day. It is by royal charter in England that boroughs have the right of sending members to parliament, and that municipal bodies, universities, colleges, and companies are incorporated and endowed with powers and privileges; and in the United States, the act of the legislature creating a corporation is called its charter.

**CHARTER PARTY**, a contract relating to the hire or chartering of a ship. The owners find the vessel with all proper sails, tackle, and necessary outfit of every description; they also usually provide a captain and crew, whom they victual and pay, and also insure their own vessel. The person who hires the vessel is the charterer. The hire may be paid either by the month or by the voyage; and the contract may either terminate on arrival at a port of destination, or may provide for taking in a fresh cargo there, and proceeding to another port. The provisions vary in every charter party according to the requirements of the parties to the contract.

**CHARTERHOUSE** (Fr. *Chartreux*, a Carthusian convent), a celebrated modern school and charitable foundation for aged soldiers and merchants in the city of London. The site it occupies was bought for a public burial place, during the great plague of 1349, by Sir Walter de Manny, who afterward established on it a convent of Carthusians. After the dissolution of the religious houses by Henry VIII. it pass-

the battle of the people. Among these Cobbett made a conspicuous figure. His "Political Register," first, commenced on high tory principles, was afterward turned to the popular side; and his powerful common-sense articles aided the cause effectively, while his conduct under numerous convictions for libel set an example of submission to the laws. The rapidly succeeding deaths of Lord Castlereagh, Lord Liverpool, and Mr. Canning, the quarrels of the king and queen, some improvements in the state of trade, and the abundant harvest of 1822, distracted attention from political questions. The fire, however, was smouldering, not extinct. In 1827, "a national union of the working classes," the idea of which was borrowed doubtless from Robert Owen's plans, was founded at Birmingham, of which Lovett and Collins were the promoters, and which included among its members a large proportion of the middle classes as well as working men. These political unions, and the concentrated strength which they displayed, forced the attention of parliament; and to them must be attributed that measure of parliamentary reform which passed in 1832. The measure had already been brought forward in 1830, and in 1831 had passed the commons, but had been rejected by the lords; but the determined attitude taken by the people compelled the retirement of many of its active opponents, and the reform act was passed in a very mutilated state, embracing, however, a portion of the principles claimed, viz.: the disfranchisement of nominal constituencies, and the substitution of others which had, by population and wealth, the right to be represented in the great council of the state. From this period chartism as a separate development in the history of the nation dates. Whatever was gained by the reform act fell to the middle classes; the working men gained nothing. The suffrage was based on rateable property, and the great requisite of the ballot box was left unnoticed. George Grote, the distinguished historian of Greece, repeatedly brought forward his measure for the ballot, which was laughed out of the reformed house, and he retired from political life. The new poor law of 1835 further exasperated the working men against the whigs or reformers, whose partiality for the political economists of the Manchester school the chartists considered decidedly hostile to the interests of the working classes. The poor rates had always been a grievous burden; but the object of the new poor law was to make the relief as distasteful as possible to the recipient, and to place the distribution of the funds locally collected under the superintendence of central authority. With this object the parishes were joined into unions, while the internal regulations of the workhouses were of the most arbitrary character. They were generally considered, as indeed they were, little better than prisons, and the food was often inferior to that of the prisons. To render parochial relief more irksome, out-door relief was discouraged,

and applicants were driven "into the house." Trades unions were now formed throughout the country, with the object of fixing the rate of wages at something above a starvation standard; and with this purely social question the political question of chartism was incorporated. A convention of the chartist leaders sat in London, which was attended by delegates from all the bodies in the country and manufacturing districts. Chartism, as a political organization, had but little sympathy or encouragement in the agricultural districts; but the distress which was felt by the laborers created discontent, which found its expression in incendiarism, and "Swing," the watch-word of the laborer, became the terror of landlords and farmers. The engrafting of social reforms upon the purely political objects of the early associations was premature, and the avowal of extreme views by a section of the chartists who styled themselves "physical force men," alienated the middle classes from their cause, and even caused dissension and disruption in their own ranks. The radical members of the house of commons who were willing to befriend their cause found themselves embarrassed by the intimidating doctrines of the physical force men, and not less so by the direct interference with trade and with the laws of demand and supply contemplated by the trades unions. These were elements of discord, and arrayed the manufacturers and capitalists against their cause; and the liberals, who, in the cause of reform, had favored political unions, now discouraged them. Nevertheless, upon the presentation of a petition in 1839, its prayer was supported by 46 members, including some of the most eminent leaders of the newly-styled radical party. The physical force men endeavored to precipitate the march of events. Finding the petition disregarded, and the working men of the metropolis indifferent to the cause, they adjourned the convention to the northern districts, and endeavored to organize a combined revolutionary movement. Some insignificant demonstrations were made in the north, which were put down by the local police, and which were so mixed up with turn-outs for wages, and with hatred of mills and mill-owners, that the real end of chartism was lost sight of. In Newport alone, in South Wales, Frost, Williams, and Jones succeeded in getting up an insurrectionary movement among the miners, which was instantaneously quelled by a small party of military quartered on the spot; and the leaders, being brought to trial, were transported. In 1840 a new association was organized at Manchester, of which Feargus O'Connor, a member of parliament, was the ostensible head; but the prime movers were Lovett and Collins, the chiefs of the old unions, who had managed to escape the hand of the law. The chartists supported the anti-corn-law league, but the bond of union between themselves and the middle classes was broken. In 1841 a monster petition, with upward of a

million of signatures, was presented to the house of commons by Feargus O'Connor, praying for the release of the chartist convicts, and for the passage of a law embodying the six points. Mr. O'Connor propounded a land scheme to enable the chartists to become small freeholders, and thus to increase their votes; but the affair, from mismanagement, turned out a bubble, to the great loss and disappointment of the contributors. Chartistism fell for some time into neglect, and disappeared from public view until 1848, when the movements consequent on the French revolution aroused it, and an attempt was made to bring about a grand organized demonstration in London. Bodies of men were to march from the manufacturing districts, and from all parts of London, to hold a great meeting. There they were to be addressed by Mr. O'Connor and other important members of their party, and they were afterward to make a display of their numerical strength by parading in front of the houses of parliament. The intention was peaceable; but the doctrines of the ultra socialists in France, with whose name chartism had been coupled, alarmed the middle classes of London, and this temper completely neutralized the chartist programme. The demonstration took place in April; the government made no display of military force, although they took every precaution against any rising; no less than 150,000 residents in the metropolis came forward, and were made special constables. A large body of London chartists assembled at the place of meeting, but the county contingents did not come in; and Mr. O'Connor, fearing lest the spirit which he had evoked might be too potent, withdrew from the meeting. The demonstration began with a silent meeting, and ended with a peaceable parade through the public streets. The public tranquillity has not been disturbed since by apprehensions of chartism, and in 1856 Mr. John Frost was pardoned and permitted to return from transportation. Lord Brougham, on the occasion of presenting a petition, in July, 1857, declared himself in favor of an extended suffrage, but still on the basis settled by the reform of 1832, and by no means as a recognition of democratic principles. During the very same week a great meeting of non-electors was held at Rochdale, in the manufacturing districts, when the leading points of chartism were discussed and reaffirmed. One of those points, the abolition of the property qualification of members of parliament, was made the law of the realm in the summer of 1858.

CHARTRES, an arrondissement and city of

France, in the department of Eure-et-Loir: pop. of the former in 1856, 111,957, and of the latter 18,925. The arrondissement comprises 8 cantons and possesses 275,000 acres of grain land, 2,500 vineyards, 8,000 of various crops, 55,000 of meadow, 95,000 of fallow land, and 28,000 of wood and forest. The annual value of the raw material employed in manufactures is \$3,500,000, and of manufactured goods \$4,200,000. The number of hands employed is 130,000. The daily wages are for men 42 cents, and for women 17½ cts.—The city of Chartres is the chief town of the department, situated 54 m. from Paris, on the railroad from the city to Rennes, on a slope at the bottom of which runs the river Eure, which divides the town into 2 parts, connected by a bridge planned by Vauban. Upon the site of the former fortifications are fine boulevards, and some of the modern buildings are well built, but the general appearance of the city is not prepossessing, most of the streets being narrow and crooked. The great object of interest there is the cathedral of Notre Dame, commenced in the beginning of the 11th and dedicated in the latter part of the 13th century, one of the spires not having been finished till the 16th century. The principal front presents 2 square towers surmounted by 2 lofty octagonal pyramids. The old spire, of plain architecture, but cased with stone carved like the scales of a fish, is 374 feet high. The new spire is 418 feet high, built in the florid style. The rich portals, the painted glass windows, the beautiful choir adorned with valuable works of art, and other remarkable features, combine to make this church one of the most magnificent in the world. It was covered with an iron roof in 1841, the old framework having been destroyed by fire in 1836. There are several other churches in Chartres, and among the public buildings and institutions must be mentioned the residence of the prefect, 3 hospitals, a fine botanical garden, a museum, and a library of 80,000 volumes; a communal college and a normal school, a theatre, an agricultural society, and a charitable institution recently established by Dr. Aligre, whose name it bears, with accommodations for 200 aged poor, and for 100 poor children. The town carries on an active trade in the products of the country, has an important wool market, and manufactories of woollen goods, hosiery, leather, and machinery. But it derives its chief commercial importance from its corn market, which is the best regulated in France, and the management of whose business is intrusted to a corporation of women.
